Lecture No. # 35
Sampling Distribution and Parameter Estimation

Hello and welcome to this lecture today. We are starting a new module.

(Refer Slide Time: 00:24)

This module is on probability and statistics. In last couple of modules, we have seen, we have discussed about different theories related to probability. Basically those, whatever we have discussed, is associated with the population.

Now, when we talk about the statistics, this statistics is related to **the to** few samples taken from this population. More precisely speaking, it is some of this random sampling. So, the **the** sample that we take that should be the random sample **for** from the population.

So, now, as we are using the word the population sample, so, at the starting of this lecture, we should know what does this actually means. You know that when we are talking about some of this parameters for those distribution, that we have seen in the last

lecture in this last module, that there are certain parameters are there which, is associated for some standard probability distribution, that we have seen.

So, basically we have to estimate those parameters. Those parameters when we estimate, we should estimate, we should have some sample data. From there, we should estimate those **those** parameters. Now again, the samples means, when we are taking the random samples from the population, now once we change the sample; obviously, **that** that estimation of those parameters may also change. Obviously, it will change because two samples will never be exactly identical. So, those **those** estimations also we will have some **some** distribution. So, those are basically called the sampling distribution. So, basically our first lecture that we are going to take in this module is **is** on this sampling distributions and the parameter estimation.

So, in this parameter estimation that what we will do **we will do** is based on this, some of this sampling distribution. You know that, whenever we talk about the mean or standard deviation or this type of parameters and which is estimated from the samples, those are also follow some distribution. So, we will see what that distribution refers to and then we can go for its estimation. Now, in the **in the** estimation theory also, we can do this estimation in terms of for two different types. One is that, that it is the point estimation. The point estimation means just one value. I can estimate from whatever information that is available to me through the random samples. Or, what I can do is that, I can look for some of this interval **of this** of this estimation.

So that, this is the interval, this is the lower limit, and this is the upper limit of this particular parameter. So, that it will be more logical to say or **in the** in the statistical sense, that instead of giving a single value as the estimate, sometimes it is preferable to give some of this interval. So, the all these things we will discuss in this lecture.

(Refer Slide Time: 03:30)

So, our outline of today's lecture is that, first we will discuss about the population and sample, then the random sampling and the point estimation. As I was mentioning, thus the single value, we will just pick up and we will just estimate from the sample. Then, properties of this point estimation and there are two methods for this estimation. One is that called Method of moments and other one is Method of maximum likelihood. Then, the interval estimation of this mean, and then interval estimation of the variance, and then estimation of the proportion.

So, all these things will go, basically this outlines **should not be a** should not be a dead end here. So, it should continue and we should have this hypothesis testing also. Because, these are all very well related to whatever we are going to discuss. So, may be one after another, we will take all these topics. So, to discuss about our **the** statistics, which is related to each and every point, whatever we will be discussing. We will see that what and where these things are useful to handle in some of the civil engineering problems. So, that, we will see. So to start with, we will start that about the concept of this population and sample.

(Refer Slide Time: 04:52)

Population and Sample

- Population is the complete set of all values representing a particular random process.
Example: Streamflow in a certain stream over infinite timeline.
- A sample is any subset of the entire population.
Example: Streamflow in the stream over the last 30 years.

 Probability Methods in Engineering: H7/L1 Dr. Rajib Halty, IIT Kharagpur 3

So, the population is the complete set of all values representing a particular random process. So, when we talk about this, all values which represents a particular random **random** process; that means, this all is very **very** I should say, that is including of, whatever the possible range is there, that should include everything.

So, what I can give the example is that, the stream flow in a certain stream over the infinite timeline. So, if we are collecting the time series **of the** of the stream flow value, so, there should not be a finite time over which we are looking the data. So, it should be on this infinite timeline of whatever has happened and what is going to happen, everything. So, that is what is our **our** population is. When we talk about a sample, that sample is any subset of the entire population. Its corresponding example for this stream flow that we have used here is, the stream flow in the stream over the last 30 years. So, if I just take over the last 30 years, then that particular data set that is available to us is the sample of this population.

Now, you can see that whatever the probability theory that we have discussed earlier, is basically related to its **its** entire **entire** possible values. That is, all possible values **of that** of that random process, but in reality, we never get, we never have this entire or whatever **whatever** all possible values, that is possible that we may not have.

So, we have to rely on some **some** sample and somehow we have to relate whatever we can estimate from the sample. We have to relate it to **to** its population. So, this is basically

the role of this statistics and with this, we will just see **how we can estimate the parameters** how we can estimate the required information from the samples. Then we will infer something about its population. Because as I told that, having the entire population is not possible in for almost all the cases.

(Refer Slide Time: 07:19)

So in now, in sample, I was mentioning that the random samples, when should we call that a sample is a random **is a random** sample. So, as it is impractical or and or uneconomical to observe the entire population that I was mentioning. So, a sample that is a subset is selected from the population for analysis. A sample is said to be random sample, when these two conditions are satisfying. One is that, it is the representative of the population. So, whatever the possible cases that we can see in the population, the sample should have **have** that representation in it. The second one is that, when the probability theory can be applied to it, to infer the results that pertain to the entire population.

So, the probability theory as I was telling, it is basically relates to the population. Now, if we can apply the probability theory to the sample to infer the results that pertains to the population, then we can say that, whatever the sample we are taking, that is the random sample. So, these are just the concept and with this concept, what we can do is that, we can use whatever we have seen from the probability theory, we can apply **to the** to this random samples.

(Refer Slide Time: 08:48)

Random sample from finite and infinite population

- An observation set $(X_1, X_2, X_3, \dots, X_n)$ selected from a **finite** population of size N , is said to be a random sample if its values are such that each X_i of n has the same probability of being selected.
- An observation set $(X_1, X_2, X_3, \dots, X_n)$ selected from an **infinite** population $f(x)$, is said to be a random sample if its values are such that each X_i of n have the same distribution $f(x)$ and the n random variables are independent.

Probability Methods in Dr. Rajib Maity, IIT Kharagpur 09:22

Now, the random sample for finite and infinite populations. So, you know that there are certain cases where the population can be finite, or in other cases it can be infinite, or sometimes it can be countably infinite. Even though I know that; obviously, there is some maximum number is there. But we can sometimes; we can also say that that is countably infinite. So, in such cases, what should be the random sample?

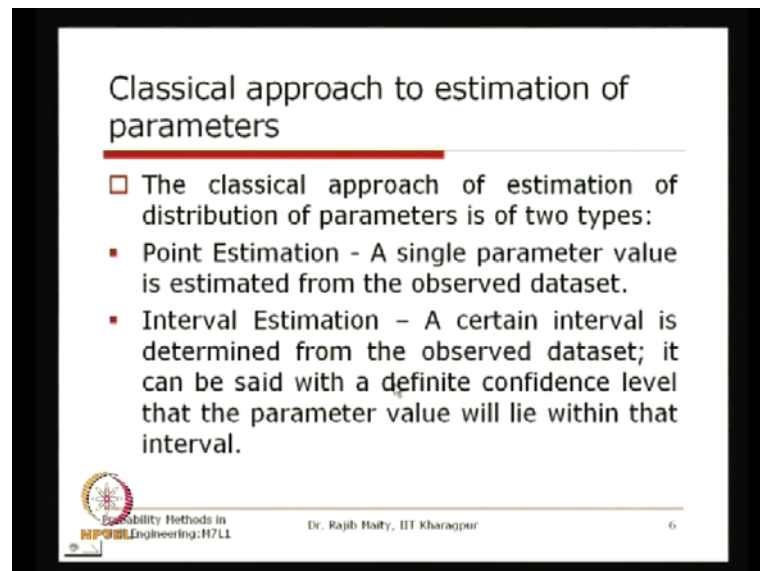

So, first we will take the case of this finite population. An observation set x_1, x_2, x_3 up to x_n is selected from a finite population of size n . So, that entire size of the population is n is said to be a random sample, if its values are such that, each x_i of n has the same probability of being selected. Now, so as we can see that there is this, the size of this population is finite that its maximum number is n . So, this x_1, x_2, x_3 , so, we can say that it is a random sample, if each of this item have the, so this, each of this element of this set have the equal probability of being selected from the population.

The second one, if the population is infinite, an observation set again that x_1, x_2, x_3, x_n is selected from an infinite population $f(x)$. So obviously, when we talk about this infinite series, we generally denote it through its probability density function. Here, it is that $f(x)$ is said to be a random sample. If its values are such that, each x_i of n have the same distribution $f(x)$ and the n random variables are independent.

So each observation, now the first observation, second observation, third up to n , these are also; we can say that these are also a random variables. So, these variables should have

the same distribution, which is $f(x)$ and which is same to the distribution of the population. And all these n elements of this set are independent to each other, then we can say that this set is one random sample.

(Refer Slide Time: 11:17)

Classical approach to estimation of parameters

- The classical approach of estimation of distribution of parameters is of two types:
 - Point Estimation - A single parameter value is estimated from the observed dataset.
 - Interval Estimation - A certain interval is determined from the observed dataset; it can be said with a definite confidence level that the parameter value will lie within that interval.

 Probability Methods in Engineering: H7/L1 Dr. Rajib Halty, IIT Kharagpur 6

The classical approach to estimation of this parameter. So, the classical approach of the estimation of this of the distribution parameters is of two types. One is the point estimation and other one is the interval estimation. So, this point estimation means a single parameter value is estimated from the observed dataset that is from the sample. So, from the sample a single parameter value is estimated.

Now, **we will** we will discuss how to estimate that parameter. That we will see so, but, here I want to trace the word single. So, when the single parameter is estimated, that is known as the point estimation. On the other hand, it will be the interval estimation, when a certain interval is determined from the observed dataset. It can be said with a definite confidence level that the parameter value will lie within that interval.

So, there are now, might be many new things here. One is that it is the interval. So, this word, the certain interval when we are predicting, then it is the interval estimation. Now, when we say that this is the interval estimation, then certain confidence level comes. So that, with this much confidence or with this much confidence and this confidence are also in this in the statistical sense. So, **sometimes** the general values that we use for this confidence levels are the 90 percent confidence, 95 percent confidence, 99 percent

confidence. So, this confidence level can vary from the 0 to 1 basically. So, means 0 percent to 100 percent. So...So, so whenever we say that it is an interval estimate, we this interval estimations are always associated with some confidence level. We will see all these things, how we can **how we can** declare that, this is the confidence for this **this** interval. But, one thing is should be cleared here now is that, this is this confidence level. If I increase the confidence level, so that means, as you can read from this sentence, that it can be said with a definite confidence level, that the parameter value will lie within that interval.

Now, suppose that I take two cases; one is that 95 percent confidence level, other one is the 99 percent confidence level. Then the, obviously, the 99 percent confidence level is more. So that, the **that the** chance of the exact parameter value will lie within that interval. In case of the 99 percent confidence, should be more so; obviously, the interval estimate that we are doing **should be more** should be more wider in case of 99 percent confidence interval, compared to what we can estimate in case of the 95 percent confidence interval. So, more the confidence level, wider is the interval. So, that is what you can we **we** can see at least at this test. We will discuss all these things.

.(Refer Slide Time: 14:18)

Random sampling and Point Estimation

- As the parameters of the distribution of a population are unknown and it is not feasible to obtain them by studying the entire population, hence a random sample is generally selected. The parameters of the distribution that are computed based on analysis of the sample values are called the estimators of the parameters.
- Thus, parameters correspond to the population; while estimators correspond to the sample.

 Probability Methods in Engineering: H7/L1 Dr. Rajib Halty, IIT Kharagpur 7

Now, the random sampling and point estimation. So, first we will take that point estimation out of these two estimates. So, as the parameters of the distribution of a population are unknown and it is not feasible to obtain them by studying the entire population, hence, the random sample is generally selected. The parameters of the

distribution that are computed based on the analysis of sample values are called the estimator of the parameters.

So, whatever the quantity that we try to estimate as the estimate of that parameter is known as the estimator. So, there are two things, one is the estimation and the other one is the estimators. So, through what **through what** function I can say, through what function I am trying to estimate that parameter that is known as the estimator.

Thus parameters correspond to the population; while estimators corresponds to the sample. So that, so this is what, when we are talking about the parameters of a distribution or of a **of a** particular probability distribution, say so, that is generally corresponds to the population. When we talk about the estimator that is correspond to the sample. So, if I take the example of this normal distribution **that we have** that we have seen earlier, is that there are two parameters now. One is the μ and the other one is the σ^2 , μ is the mean and the σ^2 is the variance.

So that, μ and σ^2 , these are the properties, **these are the** these are related, these are associated with the population. Now, how we will estimate that mean that is μ and how we will estimate that variance from a sample. So, those are the estimator and those are associated with the sample. That we will see now.

(Refer Slide Time: 16:11)

Desirable Properties of a Point Estimator

□ Desirable properties of a point estimator are:

Unbiasedness, Consistency,
Efficiency, Sufficiency

▪ **Unbiasedness:** Bias of an estimator is equal to the difference between the estimator's expected value and its true value. For an unbiased estimator of the parameter, expected value = true value.

 Probability Methods in
Engineering:17L1

Dr. Rajib Halty, IIT Kharagpur

8

So, when we say that there is a point estimator and that point estimator is, you know that should have some properties. These properties, there are four different properties that a point estimator should have before we can use that one. Because, you see that there could be many functions that we can use to estimate that particular parameter. But, so, we have to take that particular function, which is satisfying all these **all these** properties or at least the **the** more maximum number of these properties should be satisfied by those estimators.

That these four properties are the unbiasedness, consistency, efficiency and sufficiency. So, we will take one by one. The unbiasedness is the bias of an estimator is equal to the difference between the estimator's expected value and its true value. For an unbiased estimator of the parameter, expected value should be equal to the true value.

Now, when we are talking about this true value; that means, it is the value for the population that is μ . **Now, whatever the estimator, from the estimator, which is, we are getting which we should, for which we should use the sample that is available with us.** And I, as I told that these estimators also have some distribution. So, as these estimators are also having some distributions so, we can also calculate, whatever the properties that we knew from our earlier lectures and modules is that, so one is that the expected value. So, if I take the expectation of that estimator itself, so, that will reach to one **one** value.

Now, the difference between the **the** this expected value of the estimator and its true value should be obviously, the desirable thing is that, it should be as minimum as possible. So, and that is the bias. So, the estimators should be unbiased and this is the property that is written here. At least, when **when** we see that if n tends to infinity, means n , when n is the number of sample that we take. So, when n tends to infinity, then if that expectation of the estimator should be equal to its true population parameter. So, if that is the case that is basically the check for this unbiasedness.

(Refer Slide Time: 18:42)

Desirable Properties of a Point Estimator

- **Consistency:**
It refers to the asymptotic property whereby the error in the estimator decreases with increase in the sample size n . Thus as $n \rightarrow \infty$, the estimated value approaches the true value of the parameter.

Dr. Rajib Halty, IIT Kharagpur

9

Second is the consistency. It refers to the asymptotic property, whereby, the error in the estimator decreases with the increase in the sample size of n . Thus as n tends to infinity, estimated value approaches to the true value of the parameter. So, this is the consistency. That is, as we are increasing, the increasing the number of element in the sample, the estimators should be such that **that**, the value of the estimators should be should approach to the **to the** true value of the parameter, that is the parameter of the population.

(Refer Slide Time: 19:24)

Desirable Properties of a Point Estimator...contd.

- **Efficiency:** An estimator with a lesser variance is said to be more efficient compared to that with a greater variance, other conditions remaining same.
- **Sufficiency:** If a point estimator utilizes all the information that is available from the random sample, then it is called a sufficient estimator.

Dr. Rajib Halty, IIT Kharagpur

10

Third one is the efficiency. An estimator with lesser variance is said to be more efficient compared to that with a greater variance keeping, keeping other conditions same. So here, you can see that suppose, we got two estimators and both the estimators can satisfy the first two properties; one is the both are unbiased and both are what is called, that consistent. So, if both, are both are satisfying the first two condition, then we have to **we have to** select the estimator, which is having the less amount of the variance.

So, this is basically related thing, which one is more efficient **more efficient** estimator, the **the** estimator having the lesser variance is **is** more efficient in such cases. Sufficiency, if a point estimator utilizes all the information that is available from the random sample, then it is called a sufficient estimator.

(Refer Slide Time: 20:33)

Methods of Point Estimation of Parameters

□ The most commonly used methods of point estimation of parameters are:

- Method of Moments
- Method of Maximum Likelihood

Probability Methods in Engineering: M/L/L Dr. Rajib Maiti, IIT Kharagpur 11 21:07/24:50

Now, now we will discuss this thing through, there are two commonly used method of this point estimator. This will apply to one of the known distribution and can easily be handled through the, this hand calculation problem, that we will see. So, **basically** the two commonly used method for this point estimation **is are the point estimation** of the parameter are the method of moments and other one is method of maximum likelihood.

(Refer Slide Time: 21:10)

Method of Moments

- The method of moments is based on the fact that the moments of a random variable have some relationship with the parameters of the distribution.
- If a probability distribution has ' m ' number of parameters, then the first ' m ' moments of the distribution are equated to the first ' m ' sample moments. The resulting ' m ' number of equations can then be solved to determine the ' m ' number of parameters.

Probability Methods in Engineering: H7/L1
Dr. Rajib Halty, IIT Kharagpur
12

So, first we will take this method of moments. The method of moment is based on the fact, that the moments of a random variable have some relationship with the parameters of the distribution. So, whatever the sample that we are having, we will calculate what are the moments of that random variable and that should have some relationship with the parameters of the distribution. We have discussed this in the first moment, second moment with respect to the origin.

You know the first moment with respect to the origin is the mean, and second moment with respect to the origin, we generally we can take, but, we generally do not take from the second moment onwards. We take it with respect to the mean and that gives the expression for the spread of the distribution. All these things, we have discussed earlier and we have also discussed that the first moment with respect to the mean is zero. So, that concept we have discussed earlier. So, here we will use that concept to use in this method of moments.

So, if a probability distribution has m number of parameters, then the first m moments of the distribution are equated to the first m sample moments. The resulting m number of equations can then be solved to determine the m number of parameters. So, we will take two examples. One is that; say for example, that exponential distribution. So, exponential distribution is having one parameter, that you know, the λ , one parameter is having. So, the first moments, the first moment of the sample that you are having should be equated to the first sample moment. Whatever the sample that you are having, we can

also calculate what is this first moment, with respect to origin, of course, and that we can equate to **to** get that what is the estimate for this lambda.

We take another example. That is, say that normal distribution or gamma distribution, both are having two parameters. So, for normal it is mu and sigma square and for gamma you know that it is alpha and beta. So that, two parameters are there, then the first two moments, first moment and the second moment should be equated to the first two moments of the sample and this should be equated to those **those** parameters. That is, first one should be equated to the mu in case of normal distribution, and second one should be equated to the sigma square in case of normal distribution. So, there are two unknowns now and there are two equations also. That we can solve, to get what are the estimate of those parameters.

(Refer Slide Time: 23:52)

Method of Moments...contd.

□ For a sample size n , the sample mean and sample variance are:

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i, \quad s^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2$$

Thus $\bar{x}$ and s^2 are point estimates of the population mean and population variance respectively and the parameters of the distribution can be determined from these. If needed, other higher order sample moments can also be obtained to calculate all the parameters.

 Institute of Technology, Kharagpur
Dr. Rajib Halty, IIT Kharagpur

13

Now, for a sample size n , the sample mean and sample variance that what we use as their estimator, is that $\bar{x}$ is 1 by n summation of all the **all the** sample that we are having. Here, the sample size is n as it is mentioned here. So, we will sum up all the sample and divide by n , that is, basically the arithmetic mean. And this is, we can show that this is the estimator for the sample mean, which is satisfying all the properties that we can, that we have discussed. That is, four requirements for the estimator.

Now this **this** is s^2 , which is the sample variance, which is 1 by n summation of x_i minus $\bar{x}$. Again, this $\bar{x}$ is that mean estimated through this equation and this is

square summing up from this $\sum (x_i - \bar{x})^2$ equals to $(n-1)s^2$. Now, this is the point estimator for the variance.

Now, this one, it can, we can show that if we use this one, this will **not be** not be unbiased. Now, to make this one unbiased, that is, as I was telling that if the n tends to infinity, it should reach to the actual value. Then, what we have to use? We have to use that $1/(n-1)$. So, if we use that $n-1$, so, in many text what you will see that this estimator for this variance is that $1/(n-1)$. So, that minus 1 is basically to make the estimator unbiased. And you know that, this minus 1, that we are talking about is basically a, we can say that it is a, it is that degrees of freedom. So, one degree of freedom is lost here, that is why we have to, we need to get that $n-1$. Why it is lost is that, we are using this mean which is also estimated from the sample itself.

So, that is why. So, one degrees of freedom is lost here, and so, we have to write that $n-1$. Now, somehow if you know what is the population mean and if you can replace this $\bar{x}$ with respect to the population mean, that is $x_i - \mu$, that square and **if you** if we use this quantity, then there is no need to make that $n-1$, then that $1/n$ is sufficient.

So, thus this $\bar{x}$ and s^2 are the point estimates of the population mean and the population variance. So, these are the point estimate for those things, which is obtained from the sample and the parameters of the distribution can be determined from these. So, these are the first two, **that mean the population are** the estimate for the population mean and population variance. So if needed, other higher order sample moments can also be obtained, to calculate all the parameters.

So that means, that we can go to the skewness. With sample estimate of the skewness, we can go to the sample estimate of the **kurtosis** and all.

(Refer Slide Time: 27:10)

Method of Moments...contd.

- The relation between parameters of some common distributions and the moments are:
 - In case of normal distribution, parameters μ and σ^2 are equal to the mean and variance
$$E(X) = \mu : \text{Var}(X) = \sigma^2$$
 - In case of gamma distribution, the parameters α and β are related to the mean and variance as follows:
$$E(X) = \alpha\beta : \text{Var}(X) = \alpha\beta^2$$

 Probability Methods in Engineering: H7/L1 Dr. Rajib Halty, IIT Kharagpur 14

So now, the relation between the parameter of some common distribution and the moments are say for example, here we are taking the normal distribution first. There are two parameters that you know, one is that μ and other one is the σ^2 are equal to the mean and variance, like this. So, expectation of x is equal to mean and the variance is equal to σ^2 .

So, what you can see is that, directly we can use whatever, we, whatever the estimate that we have done, that we can put here to get what is this population mean and the population variance.

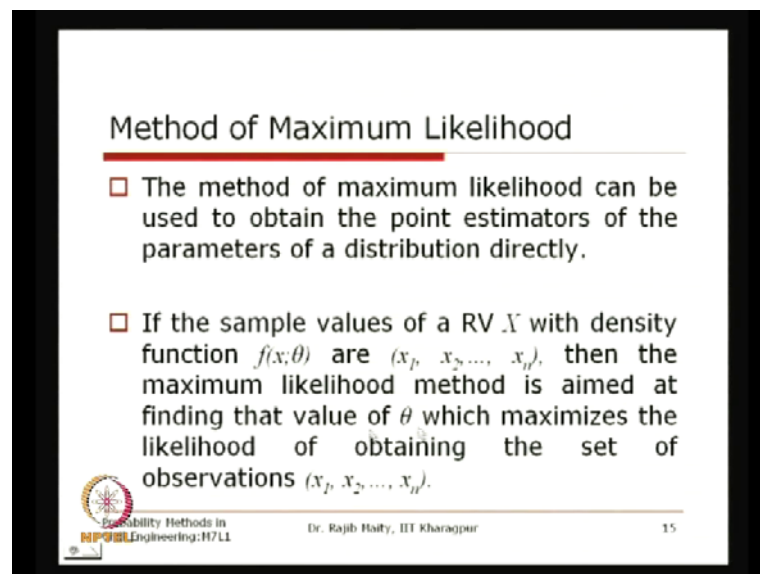

Now, in case of the gamma distribution, now the parameters are the α and β , that relates to the mean and variance as follows. That you know, that expectation of a x in case of the gamma distribution is the $\alpha\beta$ and the variance is $\alpha\beta^2$.

So, all these things we have discussed in the earlier modules. You can refer to those lectures. Here, we are just using that what we have seen in the earlier modules.

So, fine. So, as to conclude this one is that, now you are having, basically, this you can estimate from this sample. This also you can estimate from the sample. Now, if you equate this one with these two parameters, that is, what we are saying, so, we are having that two unknown α and β and there are two equations. So, these two can be

can be solved to get what is the estimate of this alpha and beta. And here, it is straightforward because, we are getting this μ , is the expectation which is directly should be equal to this $\bar{x}$. Whatever you have seen and the variance, should be that sigma square, what you have seen in this slide. Obviously, if you are using this $\bar{x}$, that is, which is also estimated from this sample, this instead of $1/n$, it should be $n-1$.

(Refer Slide Time: 29:12)

Method of Maximum Likelihood

- The method of maximum likelihood can be used to obtain the point estimators of the parameters of a distribution directly.
- If the sample values of a RV X with density function $f(x; \theta)$ are $(x_1, x_2, \dots, x_n)$, then the maximum likelihood method is aimed at finding that value of θ which maximizes the likelihood of obtaining the set of observations $(x_1, x_2, \dots, x_n)$.

Reliability Methods in Engineering: H7/L1 Dr. Rajib Halty, IIT Kharagpur 15

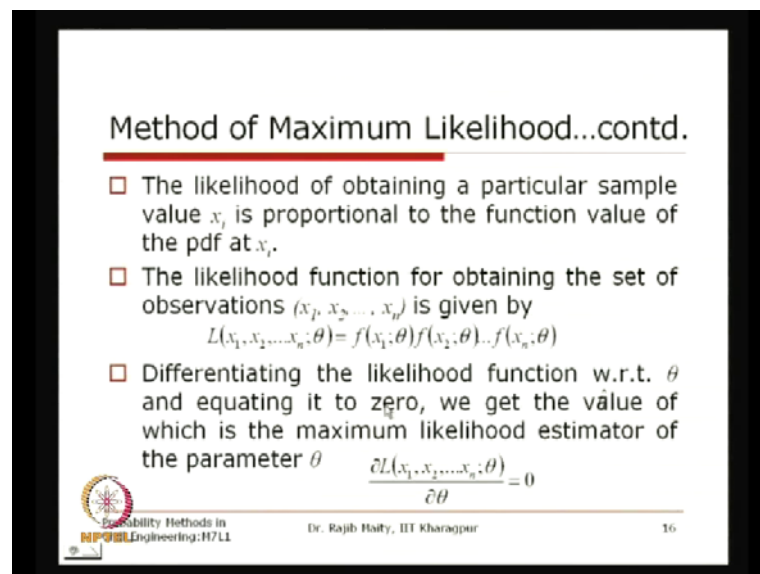

Now, the second method is that method of maximum likelihood. The method of maximum likelihood, can be used to obtain the point estimator of the θ parameters of a distribution directly.

So, there are some shortcomings of this method of moments, which we generally suppose that, sometimes the estimator that is using the method of moments, what we get is that, sometimes the solutions are once it is solved, we get that the, it is not within the θ range of these parameters. So, sometimes this kind of things are observed. So, that is the criticism over the method of moments. So there, this method of likelihood has found to be more effective. Because, here directly the distribution we are using and we are developing a likelihood function and that likelihood function is maximized to estimate that particular parameter. Now, you know that how to maximize that likelihood function. First of all, we will see what is the likelihood function and then we will maximize that one. Now, as many parameters are there, so, we have to maximize all

those parameters. So that, we will get those many equation to have to solve them to get those estimate.

So, suppose that if a sample value of a random variable x with density function $f(x)$ and the parameter is θ here are this $x_1, x_2, \dots, x_n$ then, the maximum likelihood method is aimed at finding that value of θ , which maximizes the likelihood of obtaining the set of observations $x_1, x_2, \dots, x_n$.

(Refer Slide Time: 30:54)

Method of Maximum Likelihood...contd.

- The likelihood of obtaining a particular sample value x_i is proportional to the function value of the pdf at x_i .
- The likelihood function for obtaining the set of observations $(x_1, x_2, \dots, x_n)$ is given by

$$L(x_1, x_2, \dots, x_n; \theta) = f(x_1; \theta) f(x_2; \theta) \dots f(x_n; \theta)$$
- Differentiating the likelihood function w.r.t. θ and equating it to zero, we get the value of which is the maximum likelihood estimator of the parameter θ

$$\frac{\partial L(x_1, x_2, \dots, x_n; \theta)}{\partial \theta} = 0$$

Probability Methods in Engineering: H7/L1 Dr. Rajib Halty, IIT Kharagpur 16

So, what we have to do is that the likelihood of **the of** obtaining a particular sample x_i is proportional to the function value of the pdf at x_i . So, so this x_i means from this $x_1, x_2, \dots, x_n$, we have to calculate what is that likelihood function. So, the likelihood function for obtaining the set of this observation $x_1, x_2, \dots, x_n$ is given by these values of this distribution at each point. That is, what is the value of that function at x_1 , at x_2 , at x_3 and all and their multiplication.

So, this differentiating the likelihood function with respect to θ now and equating it to 0, so, this is basically we are **we are** maximizing the likelihood function. We are finding where this likelihood function will be maximized. We get the value, that is θ value of **of** that estimate, that is $\hat{\theta}$, we can just set which is the maximum likelihood estimator of this parameter θ , that is this 1 will equate to 0 and then we will get that estimate of that $\hat{\theta}$.

(Refer Slide Time: 32:11)

Method of Maximum Likelihood...contd.

- The solution of can also be obtained by maximizing the logarithm of the likelihood function L .
$$\frac{\partial \log L(x_1, x_2, \dots, x_n; \theta)}{\partial \theta} = 0$$
- If there are 'm' number of parameters of the distribution, then the likelihood function is
$$L(x_1, x_2, \dots, x_n; \theta_1, \theta_2, \dots, \theta_m) = \prod_{i=1}^n f(x_i; \theta_1, \theta_2, \dots, \theta_m)$$
- And the maximum likelihood estimators are obtained by solving the following simultaneous equations.
$$\frac{\partial L(x_1, x_2, \dots, x_n; \theta_1, \theta_2, \dots, \theta_m)}{\partial \theta_j} = 0; \quad j = 1, 2, \dots, m$$

 Probability Methods in Engineering: H7/L1
Dr. Rajib Halty, IIT Kharagpur 17

The solution can also be obtained by maximizing the logarithm of this likelihood function. So, if we take the log also, sometimes this it will be more that. So, far as mathematical calculation is concerned, it a may become easier that will take the log of this likelihood function and will differentiate with respect to the parameter, can if there are m numbers of parameters of the distribution, then the likelihood function is like this. So, there are theta 1 theta 2 up to theta m, these are the parameters of the distribution and this is you know, that this is a multiplication sign of this at each sample point x i.

The maximum likelihood estimators are obtained by solving the following simultaneous equations. So, we will, we have to take the differentiation with respect to each parameter theta j, j can vary from 1 to up to m. And we can take this; we can take this parcel derivatives equated to 0. So, we will get m equations to solve them, to get that estimate of this m parameters.

(Refer Slide Time: 32:21)

Problem on Point Estimate

Q. The interarrival time of vehicles on a certain stretch of a highway is expressed by an exponential distribution

$$f_T(t) = \frac{1}{\lambda} e^{-\frac{t}{\lambda}}$$

The time between successive arrival of vehicles was observed as 2.2s, 4.0s, 7.3s, 11.1s, 6.2s, 3.4s, 8.1s.

Determine the mean inter arrival time λ by the
a) method of moments b) the maximum likelihood method.

Probability Methods in Engineering: H7/L1 Dr. Rajib Halty, IIT Kharagpur 18

Now, we will take one example using both the methods that we have seen just now. Both, that **that method of** method of moment and method of maximum likelihood.

So, and here we have taken that example of this exponential distribution. You know this exponential distribution here, the example is on this interarrival time of this vehicle on a certain stretch of a highway is expressed by an exponential distribution, where this $f(t)$ is equals to $\frac{1}{\lambda} e^{-\frac{t}{\lambda}}$.

Now, means some places or even in this lecture also, earlier we have, we might have used some other form, that is, $\lambda e^{-\lambda t}$. So, it does not matter. So, there just parameter is taken that $\frac{1}{\lambda}$ here. So, here also. So, the form is not changing, only thing the parameter represents in a different way. So, if we use that, the **the** other form also that is $\lambda e^{-\lambda t}$, then also **we can** we can get the same result that we see now.

So, and obviously, here this t is greater than equal to 0. Now, there are some samples has been taken, that is the time between the successive arrival of the vehicle was observed as 2.2 seconds, 4 seconds, 7.3 seconds, 1.1 seconds, 6.2 second, 3.4 seconds and 8.1 seconds. So, this is a sample that we have collected. Now, determine the mean, inter arrival time that is λ by, so, or I, if I do not even want to mention this; what is this, I just want to estimate, what is the parameter λ for this distribution by two

methods. One is the method of moments and other one is the method of maximum likelihood.

(Refer Slide Time: 35:12)

Problem on Point Estimate...contd.

Soln.:

(a) The first moment about the origin of $f_X(x)$ is

$$\mu = \frac{1}{\lambda} \int_0^{\infty} t e^{-t/\lambda} dt$$

or, $\mu = -\left[t e^{-t/\lambda} + \lambda e^{-t/\lambda} \right]_0^{\infty}$

or, $\mu = \lambda$

Therefore, $\lambda_0 = \mu = \bar{X} = \frac{1}{7} \sum_{i=1}^7 t_i = 6.04 \text{ s}$

Probability Methods in
Engineering: H7/L1

Dr. Rajib Halty, IIT Kharagpur

19

So, first the method of moment. When we have said that, we should take the moment with respect to the origin and that we should equate with this mean. So, if we take this moment, you know that this is a first moment with respect to mean that we have discussed in the earlier classes, is that that t multiplied by that distribution. Taking this integration over the entire support of this distribution and here this exponential distribution having the support 0 to infinity. So, we will take this integration and if we solve this one, we can see that this μ is equals to λ here. So, this is μ . So, the λ is equals to μ , which is, we can obtained from this sample of this $\bar{x}$, which is the estimator for this mean. So, this 1 by 7 summation of all this t_i , so, it is the arithmetic mean. So, 6.04 second is the estimate for this λ .

Now, if we use the other form of this exponential distribution that is **that is** $\lambda e^{-\lambda t}$ then, you can see that this μ will become that 1 by λ . So, there the λ will be equals to 1 by $\bar{x}$ and this will be 1 by 6.04 second. So, it depends on what way parameters is used here.

(Refer Slide Time: 36:26)

Problem on Point Estimate...contd.

(b) Assuming random sampling, the likelihood function of the observed values is

$$L(t_1, t_2, \dots, t_7; \lambda) = \prod_{i=1}^7 \frac{1}{\lambda} \exp\left(-\frac{t_i}{\lambda}\right)$$
$$= (\lambda)^{-7} \exp\left(-\frac{1}{\lambda} \sum_{i=1}^7 t_i\right)$$

The estimator can now be obtained by differentiating the likelihood function L with respect to λ .

Probability Methods in Engineering: H7/L1

Dr. Rajib Halty, IIT Kharagpur

20

And, the other one that is use of this **maximum likelihood** maximum likelihood function. That is, so, assuming the random sampling, the likelihood function of the observed value is that is t_1, t_2, t_3 up to t_7 . So, all this sample will take and this will get what is the likelihood function first.

So, $1/\lambda$ by $e^{-t_i/\lambda}$. So, $e^{-t_i/\lambda}$ by $1/\lambda$. So, at all this observation, we are getting this value and we are multiplying them with each other. So, this λ^{-7} exponential of this value, we will get and the estimator can now be obtained by differentiating the likelihood function L with respect to the parameter that is λ .

(Refer Slide Time: 37:12)

Problem on Point Estimate...contd.

Hence, $\frac{\partial L}{\partial \lambda} = -7\lambda^{-8} \exp\left(-\frac{1}{\lambda} \sum_{i=1}^7 t_i\right) + \lambda^{-8} \exp\left(-\frac{1}{\lambda} \sum_{i=1}^7 t_i\right) \frac{\sum_{i=1}^7 t_i}{\lambda^2} = 0$

or, $\lambda^{-8} \left(-7 + \frac{1}{\lambda} \sum_{i=1}^7 t_i\right) \exp\left(-\frac{1}{\lambda} \sum_{i=1}^7 t_i\right) = 0$

or, $\frac{1}{\lambda} \sum_{i=1}^7 t_i = 7$

or, $\lambda = \frac{1}{7} \sum_{i=1}^7 t_i$

or, $\hat{\lambda} = 6.04s$

Reliability Methods in
Engineering: H7/L1

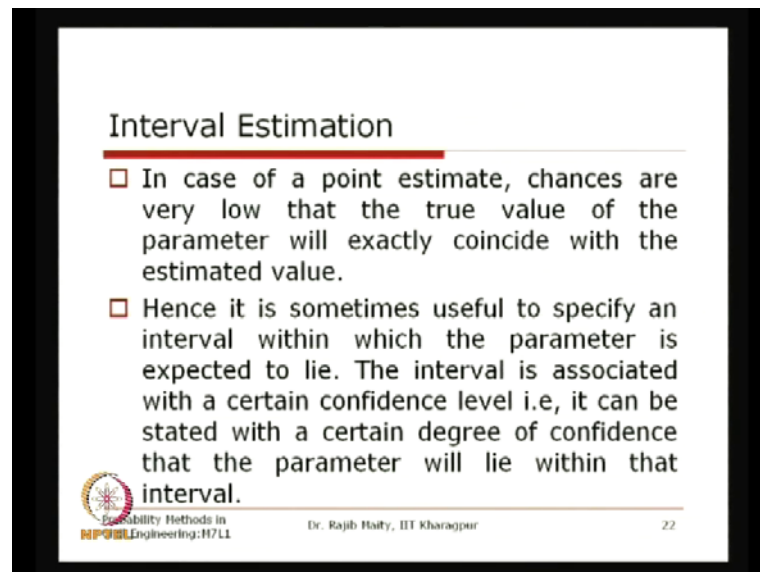

Dr. Rajib Halty, IIT Kharagpur

21

So, if we do that that, if we do this derivative, we take with respect to the lambda, then we will get this form. If we just equate it to the 0, then after solving this form, you will get that again the lambda is equals to 6.04 second.

So, for this one, this example, that we have shown for both the method, whatever the parameter that we have **that we have** estimated are same for the lambda is equals to 6.04 second for both the methods; that is method of moment and method of maximum likelihood. But sometimes, in some problems, in some distribution this two estimate may not be same.

(Refer Slide Time: 37:56)

Interval Estimation

- ❑ In case of a point estimate, chances are very low that the true value of the parameter will exactly coincide with the estimated value.
- ❑ Hence it is sometimes useful to specify an interval within which the parameter is expected to lie. The interval is associated with a certain confidence level i.e, it can be stated with a certain degree of confidence that the parameter will lie within that interval.

 Probability Methods in Engineering:H7/L1

Dr. Rajib Halty, IIT Kharagpur

22

So, next we will take that interval estimation. So, as I was telling that in this point estimation, we generally get a single value. That is, what we have seen in **in** the previous example also, in both the methods of method of moments or method of maximum likelihood, we get the single value. That is, the lambda value that you have seen that 6.04 second. So, only a single value that you have seen in the point estimate.

Now, the **the** interval estimate, we generally look for a interval, in which, with some confidence that actual value of the parameter should lie. So, this is what this interval estimation.

So, in case of point estimate, the chances are very low that the true value of the parameter will exactly coincide with the estimated value. So, as the sample is finite, always there will be some error. So, hence sometimes, it is desirable or it is useful to specify an interval within which the parameter is expected to lie.

The interval is associated with certain confidence level that is, it can be stated with certain degree of confidence that the parameter will lie within that interval. So, this is what we have, we are discussing few minutes ago, that **always this estimate** whenever we say that this is **the this is** the interval, so, that interval must be associated with some of some confidence level, in statistical sense.

(Refer Slide Time: 39:27)

Confidence interval of Mean with known variance

- For a large sample n ($n \geq 30$) if $\bar{x}$ is the calculated sample mean and σ^2 is the known variance of the population, then $\frac{\bar{x} - \mu}{\sigma / \sqrt{n}}$ is a standard normal variate.
- The confidence interval of the mean μ is given by
$$\bar{x} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}} < \mu < \bar{x} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$$
where $(1-\alpha)100\%$ is the degree of confidence and $z_{\alpha/2}$ is the value of standard normal variate at cumulative probability level $\alpha/2$ and $(1-\alpha/2)$.

 Probability Methods in Engineering: H7/L1 Dr. Rajib Halty, IIT Kharagpur 23

Well. So, the confidence interval of the mean with known variance. So, **so** whatever the estimators that we have seen for this mean, and as we are taking it from the sample, so, that will also have some sampling distribution; it should have. And if we somehow know what is the variance and known variance means, we know the population variance. If we know that, one then, how we can get that confidence interval for the mean. So, for a large sample n , so, large sample is again, this is a subjective word. So, generally we can, we have seen that, if n is greater than equal to 30, then you can say that in case of mean only, so, not for all in general case, in case of mean, if the sample size is greater than 30, then we can say that it is a large sample. So, in such case, if $\bar{x}$ is calculated sample mean and the sigma square is the known variance of the population. So, sigma square I know **which is exactly** which is actual value of this population. How we know, that is the second issue, but, we know this sample **population** we know the variance of the population. Only thing we are interested to know, what is the interval for this sample mean.

Then, it is, it can be shown that this $\bar{x}$ is **is** a normal distribution with mean equals to μ , which is the population mean and the variance of this $\bar{x}$, that is, this sample mean, variance of the $\bar{x}$ is sigma square by n or the standard deviation of this $\bar{x}$ is sigma by square root n .

So, this what I want to repeat once again, that this sigma square is the variance of the population for the random variable x . Now, what we are talking about is this $\bar{x}$. This x

bar is again another random variable, which is normally distributed having the same mean of the population, which is μ and its standard deviation is $\sigma/\sqrt{n}$.

Now, you know from the, from our earlier lecture, that this if we just take this quantity now, that this, what is the random variable minus its mean divided by its standard deviation is a **is a is a** standard normal distribution. So, that is why this $\bar{x}$ minus μ by $\sigma/\sqrt{n}$ is a standard normal variate.

So, now for once we know that this is the quantity and this follow a standard normal distribution. Now, we can calculate whatever the confidence interval that we are looking for. So, the confidence interval of the mean μ is given by is this, that is, $\bar{x}$. Basically, we are just equating it with two side of this standard normal distribution.

(Refer Slide Time: 42:36)

Now, if you **if you** see this one here. So, if this is your standard normal distribution, then basically that **that** quantity, that is $\bar{x}$ minus μ by $\sigma/\sqrt{n}$, that should, so, this is your, this is the standard normal distribution. So, this the distribution that I have drawn is a standard normal distribution. So, this should lie between these two values here, should in such a way that this area should be your, that whatever the confidence limit that you wish to specify.

Now, so, **so** this is the confidence level of that estimated that it should have. Now, if I just say that this **this** confidence level is, say at some **some** level, say that 95 percent

confidence level. So, whatever is remaining here is your 0.025 and whatever is remaining here is again 0.025.

So, we have to find out these two values. Suppose that, if I just put that one, $z_{\alpha/2}$ and $-z_{\alpha/2}$ this is say that $z_{\alpha/2}$; obviously, this will be the negative side, this is 0 for the standard 1. So, this one, so, this quantity should lie between this $z_{\alpha/2}$ and this $-z_{\alpha/2}$, where this $z_{\alpha/2}$ are basically the cumulative probability up to that point.

So... So, this $\bar{x} - \mu$ divided by $\sigma / \sqrt{n}$ should lie between this two, $z_{\alpha/2}$ and $-z_{\alpha/2}$, sorry, $z_{\alpha/2}$. So, z is the z variate, is the z reduced variate for this standard normal distribution. And, this $z_{\alpha/2}$ is this part where we are. So, the confidence, if I just want to relate to this confidence level is that, it will be that $1 - \alpha$ multiplied by 100 confidence level. So, this is the confidence level that we can say. So, that if this area, this white area is the $1 - \alpha$, then this 95, that is here in case of 0.25 here, can be relate to this one.

So, this is that confidence interval that we are, that is the confidence level that we are talking about for this, once we can put this limits as this $z_{\alpha/2}$. Now, if I just do some arithmetic change, then it will come like this; that is, μ should be equals to here that $\bar{x} \pm z_{\alpha/2} \sigma / \sqrt{n}$. Here it will be, $\bar{x} - z_{\alpha/2} \sigma / \sqrt{n}$ to $\bar{x} + z_{\alpha/2} \sigma / \sqrt{n}$.

So, you remember, that even this $z_{\alpha/2}$ when we are talking about. So, so this $z_{\alpha/2}$, it is automatically, when it is coming to this negative side, it have this negative value. So, do not confuse that this will have $-z_{\alpha/2}$ the negative value and this again another negative sign is here. So, this will not be the plus. So, this is a single value that we are using here, which should have that this particular quantity. From the symmetry, both the values will be same numerically, only this one will be positive and this one will be negative.

So, this is what is mention here, that is $\bar{x} - z_{\alpha/2} \sigma / \sqrt{n} < \mu < \bar{x} + z_{\alpha/2} \sigma / \sqrt{n}$. So, you know that from the continuous distribution less than and less than equals to are same.

Where, this 1 minus alpha into 100 percent, this is the quantity, which is the degree of confidence. And here, this minus plus z alpha by 2 is the value of the standard normal variate, at the cumulative probability level alpha by 2 and 1 minus alpha by 2.

So, when you are taking this minus sign minus z alpha by 2, this is **is** the probability level at this alpha by 2. So, if it is 95, if you put this alpha equals to 0.95 then; obviously, 1 minus, so, **sorry**, this is full is equals to 0.95, then alpha will become 0.05 and this alpha by 2 will become 0.025.

Now, at this 0.025, this z alpha by 2 will be, say if it is 1.96, you know that this value will be 1.96. So, this will be $\bar{x}$ minus 1.96 multiplied by sigma by square root n and here also, plus 1.96 sigma by square root n this will come.

(Refer Slide Time: 47:36)

Confidence interval of Mean with unknown variance

- For a small sample n ($n < 30$), if $\bar{x}$ is the calculated sample mean and s^2 is the calculated sample variance, then the random variable $\frac{(\bar{x} - \mu)(s/\sqrt{n})}{\sigma}$ follows t-distribution with $(n-1)$ degrees of freedom.
- The confidence interval of the mean μ is given by $\bar{x} - t_{\alpha/2} \frac{\sigma}{\sqrt{n}} < \mu < \bar{x} + t_{\alpha/2} \frac{\sigma}{\sqrt{n}}$

Probability Methods in
Engineering: H7/L1

Dr. Rajib Halty, IIT Kharagpur

24

Now, as we are discussing that if the sample is more, if the sample is large, if it is more than 30, now in other case, if the sample size is small, say if it is less than 30 and if the $\bar{x}$ is the calculated sample mean and this, then this s^2 is this calculated sample variance, then the random variable $\bar{x}$ minus μ divided by s square root of n , follow a t distribution with n minus 1 degrees of freedom.

Here you see, this is that the variance, we do not know that is the unknown variance. So, this one also we have to calculate from the **from the** sample itself. So, this also, again

when you take that this $\bar{x}$ minus this population mean divided by this sample variance divided by square root n .

So, this one instead of following this standard normal distribution, it will follow the t distribution with $n - 1$ degrees of freedom. So, this t distributions and all we have discussed earlier. Only thing is that, if the sample size is small, this quantity will follow the t distribution. If the sample size is more and **this** variance is known, then this will follow a normal distribution.

So, here in this case, this **this** confidence interval will be $\bar{x} \pm t_{\alpha/2} \frac{\sigma}{\sqrt{n}}$ and $\bar{x} \pm z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$. So, this is a t distribution with degrees of freedom $n - 1$. And, you can see even that from standard text book about this t distribution, when this n **n** goes beyond 30, then the value of this $t_{\alpha/2}$ and the $z_{\alpha/2}$ are essentially same.

(Refer Slide Time: 49:30)

Confidence interval of Mean with unknown variance...contd.

where $(1-\alpha)100\%$ is the degree of confidence and $\pm t_{\alpha/2}$ is the value of standard t -distribution variate at cumulative probability level $\alpha/2$ and $(1-\alpha/2)$. It can be obtained from the t -distribution table.

□ Though it is assumed that the sample is drawn from a normal population, the expression applies roughly for non-normal populations also.

Probability Methods in
Engineering: H7/L1

Dr. Rajib Halty, IIT Kharagpur

25

So, where this again, the $1 - \alpha$ into 100 percent is the degree of confidence and $\pm t_{\alpha/2}$ is the value of the standard t distribution variate at cumulative probability again, that $\alpha/2$ and this $1 - \alpha/2$. So, basically the difference between the t and the **and the** standard normal distribution is at this lower end level, where you will get a **a** wider estimate of the interval because, **the** when the sample size is less, as there are uncertainty is more.

Though it is assumed that the sample is drawn from a normal population, the expression applies roughly for non normal population also. So, basically when the population is normal distributions, these are very well acceptable method. But, even though it is non normal also, this method we can apply.

(Refer Slide Time: 50:26)

Problem on Confidence interval of Mean with known variance

Q. Thirty concrete cubes prepared under a certain condition. The sample mean of these cubes is found to be 24 KN/m^3 . If the standard deviation is known to be 4 KN/m^3 , determine the 99% and the 95% confidence interval of the mean strength of the concrete cubes.

 Probability Methods in
Engineering: H7/L1

Dr. Rajib Halty, IIT Kharagpur

26

So, we will take one example of this, whatever we have seen, is that 30 concrete cubes prepared under certain condition. The sample mean of these cubes is found to be 24 kilo Newton per meter cube, if the standard deviation is known to be 4 kilo Newton per meter cube, determine the 99 percent and 95 percent confidence interval of the mean strength of the concrete cube.

So, this 4 kilo Newton per meter cube is known; it is from the population. And this one, when we say that this one is obtained from this sample.

(Refer Slide Time: 51:10)

Problem on Confidence interval of Mean with known variance...contd.

Soln.:

(a) For the 99% confidence interval,
 $1-\alpha=1-0.99=0.01$
From the standard normal table,

$$P(Z \leq z_{\alpha/2}) = 1 - \frac{\alpha}{2}$$
$$\text{or, } P(Z \leq z_{0.005}) = 1 - 0.005$$
$$\text{or, } P(Z \leq z_{0.005}) = 0.995$$
$$\text{or, } z_{0.005} = 2.575$$

Now, $\frac{\sigma}{\sqrt{n}} z_{\alpha/2} = \frac{4}{\sqrt{30}} (2.575) = 1.88$

 Reliability Methods in Engineering: H7/L1 Dr. Rajib Halty, IIT Kharagpur 27

So, if we want to solve this one, then you know, that we first of all, we will get that what should be the quintile value for this z alpha by 2 and this is for this 99% confidence interval from the standard normal table. You can see that it is 2.575, which is z alpha by 2 value. So, this sigma by square root n multiplied by z alpha by 2 is equals to 1.88, whatever the data is available.

(Refer Slide Time: 51:35)

Problem on Confidence interval of Mean with known variance...contd.

The 99% confidence interval of the mean strength of the concrete cubes is

$$(24 - 1.88; 24 + 1.88) \text{ kN/m}^2$$
$$\text{i.e., } (22.12; 25.88) \text{ kN/m}^2$$

(b) To determine the 95% confidence interval,

$$P(Z \leq z_{0.025}) = 1 - \frac{0.05}{2}$$
$$\text{or, } P(Z \leq z_{0.025}) = 0.975$$
$$\text{or, } z_{0.025} = 1.96$$

 Reliability Methods in Engineering: H7/L1 Dr. Rajib Halty, IIT Kharagpur 28

So, the 99 percent confidence interval will be the mean minus that quantity 1.88 and mean plus 1.88. So, the confidence interval is 22.12 and 25.88 kilo Newton per meter square. Sorry.

To determine the 95 percent confidence interval, again we have to find out the z alpha by 2 and this is your 1.96, earlier it was 2.575. So, it is now 1.96.

(Refer Slide Time: 52:03)

Problem on Confidence interval of Mean with known variance...contd.

$$\text{Now, } \frac{\sigma}{\sqrt{n}} z_{\alpha/2} = \frac{4}{\sqrt{30}} (1.96) = 1.43$$

The 95% confidence interval of the mean strength of the concrete cubes is
 $(24 - 1.43, 24 + 1.43) \text{ KN/m}^2$
 i.e., $(22.57, 25.43) \text{ KN/m}^2$

It is more likely that the larger interval will contain the mean value than the smaller one. Hence the 99% confidence interval is larger than the 95% confidence interval.

Reliability Methods in Engineering: H7/L1 Dr. Rajib Haity, IIT Kharagpur 29

If we calculate this one, it will become 1.43 and the 95 percent confidence interval of the mean strength of this concrete will be 24 minus 1.43 and 24 plus 1.43. So 22.57 and 25.43 kilo Newton per meter square. Sorry. This is or this is the density sorry **sorry** this is the density. So, this it is kilo meter per meter cube.

But, what we should observe here is that there are two confidence interval. We have determined one is the 99 percent confidence interval and other one is the 95 percent confidence **confidence** interval.

So, the 95 percent confidence interval is 22.57 to 25.43 whereas, the 99 percent confidence interval is 22.12 and 25.88. So, you can see that this 99 percent confidence interval is wider, because it is more likely that the larger interval will contain the mean value than the smaller one. So, hence the 99 percent confidence interval is larger, when the 95 percent confidence interval **whereas** compare to this 95 percent confidence interval.

So, this example, that we have used, it is we **we we** have taken that a variance is known. So, once we **we** have decided the variance is known, we have used the standard normal distribution. But, in the other case, we have seen that sometimes the sample size is less and we have to **we have to** use, in that case, we have to use that, what is the t distribution. From the t distribution interval, we have to use that one.

So, maybe we will take up the same example, but, in that time we will just declare that whatever the distribution, whatever the standard deviation that we got, it is not from the population, but, from the sample. So, that example we will basically start from the next lecture and after that we will take what should be the, that estimation for the other parameters like the variance proportion and all. And, we will also relate, we will also see about this test of hypothesis which is obviously, essential when we are comparing the mean of from the two different samples or the variance or proportion from. So, when it is related to two different samples, then we have to go for those testing. So, we will start from this point in the next lecture. Thank you.
