**Lecture 50**  
**Surface Water and Ground Water Interaction**

Welcome to this lecture of the course computational hydraulics. We are in module 6 interaction of different types of flow and this is unit number 1, surface water and ground water interaction.

(Refer Slide Time: 00:37)

The image shows a presentation slide with a white background and a red header and footer. The header contains a navigation menu with the following items: Problem Statement, Information Transfer Mechanism, Algorithm, and References. The I.I.T. Kharagpur logo is also present in the header. The main content of the slide is centered and includes the following text: **Module 06: Interaction of Different Types of Flow**, **Unit 01: Surface Water and Groundwater Interaction**, **Anirban Dhar**, Department of Civil Engineering, Indian Institute of Technology Kharagpur, Kharagpur, and National Programme for Technology Enhanced Learning (NPTEL). The footer contains the text: Dr. Anirban Dhar, NPTEL, Computational Hydraulics, and 1 / 16.

In this particular module I will be talking about interaction of different kinds of flow and specifically this module has got only one unit and this is surface water and ground water interaction. But at the same time I will usually talk about the pipe flow during this interaction. Learning objective, at the end of this unit students will be able to solve unsteady interaction problem between channel flow, surface flow and groundwater flow.

(Refer Slide Time: 01:24)

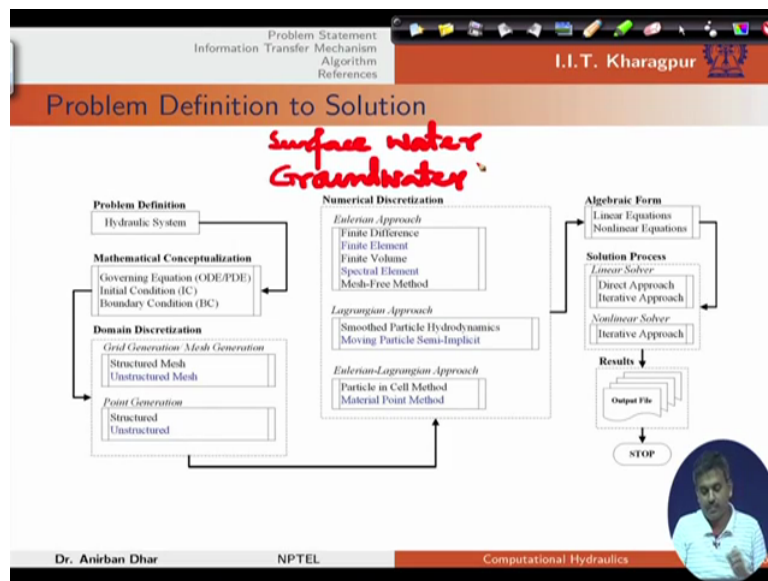

The slide is titled "Learning Objective" and is part of a presentation from I.I.T. Kharagpur. The navigation menu at the top includes "Problem Statement", "Information Transfer", "Mechanism", "Algorithm", and "References". The main content area contains a single bullet point: "• To solve unsteady interaction problem between channel flow, surface flow and groundwater flow." The slide footer identifies the speaker as "Dr. Anirban Dhar" and the course as "Computational Hydraulics".

So this is our general structure of the course. For a particular problem we need to identify the problem definition which is for the hydraulic system then we need to mathematically conceptualize the problem in terms of governing equation, initial condition and boundary conditions. After that we need to discretize the domain either with structured unstructured grid or point method that is mesh free approach.

And finally we need to discretize the governing equations and we need the algebraic form of the governing equation. So governing equations or discretized form of the governing equation these maybe linear or nonlinear in nature. And depending on that we need to apply different solvers. For linear problems we have direct or iterative approaches and for nonlinear method we have only iterative approach available. But in this case for interaction we have three components one is surface water, next one is ground water.

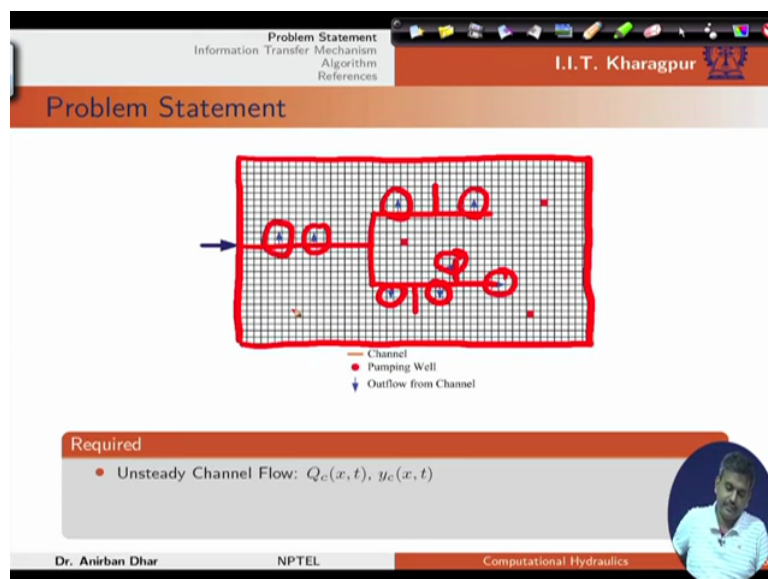

Now in the surface water and ground water can be conceptualized or mathematically conceptualized in terms of single governing equation. But whatever we have discussed in this course in that one we have talked about one dimensional channel flow, two dimensional surface flow and two dimensional ground water flow. So let us integrate this one dimensional channel flow, two dimensional surface flow and two dimensional ground water flow for this problem.

(Refer Slide Time: 04:09)

Now let us define the problem. What is the problem statement? Problem statement is let us say this is the area which is a particular command area or irrigation command area and we need to supply water for this irrigation command through 1D channel network. This is our channel network and within this channel network there are number of branches available. And we have this blue ones these are outlet points. Through these outlet points the water is supplied to the field.

(Refer Slide Time: 05:11)

Now for a particular irrigation system water is applied at the head of the channel reach and this water may be sufficient or in some cases may not be sufficient for the irrigation

command. Then we need to pump out water from the ground water system. So these three are pumping wells.

(Refer Slide Time: 05:51)

Problem Statement  
Information Transfer Mechanism  
Algorithm

I.I.T. Kharagpur

**Problem Statement**

Channel  
Pumping Well  
Outflow from Channel

**Required**

- Unsteady Channel Flow:  $Q_c(x, t), y_c(x, t)$

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

And finally when we will be applying water to the field through these outlets obviously water will travel in the field and there will be surface water flow in the field itself. And that is two dimensional in nature as per our conceptualization. Now we have three components, one is unsteady channel flow. In unsteady channel flow we need to find out what is  $Q_c$  and  $y_c$ ?  $Q_c$  is a function of  $x$  and  $t$ .  $Y_c$  is also function of  $x$  and  $t$ . What is  $Q_c$ ?  $Q_c$  is the discharge in the channel and  $y_c$  is the flow depth in the channel.

(Refer Slide Time: 07:00)

Problem Statement  
Information Transfer Mechanism  
Algorithm  
References

I.I.T. Kharagpur

**Problem Statement**

Channel  
Pumping Well  
Outflow from Channel

**Required**

- Unsteady Channel Flow:  $Q_c(x, t), y_c(x, t)$
- Unsteady Free-surface Flow (Shallow water):  $h_s(x, y, t), u_s(x, y, t), v_s(x, y, t)$

Dr. Anirban Dhar      NPTEL      Computational Hydraulics      4 / 16

Now in this case after this outflow from the channel network water will travel to the field and there will be two dimensional surface flow. So if we want to model that surface flooding or surface flow components it should be modelled through this shallow water flow equation. In shallow water flow equation  $hS$  which is the function of  $x$ ,  $y$  and  $t$  that is the total flow depth there in the field. Then we have  $u_s$  and  $v_s$ . These are also functions of  $x$ ,  $y$  and  $t$ .

Now third component which is required for the system is unsteady unconfined aquifer flow because your first layer or unconfined layer is connected directly with the surface through unsaturated zone. There will be one saturated zone and unsaturated zone in the system.

(Refer Slide Time: 08:36)

**Problem Statement**  
Information Transfer Mechanism Algorithm References

I.I.T. Kharagpur

**Problem Statement**

$h_s(x, y, t)$   
 $u_s(x, y, t)$   
 $v_s(x, y, t)$

Channel  
 Pumping Well  
 Outflow from Channel

**Required**

- Unsteady Channel Flow:  $Q_c(x, t)$ ,  $y_c(x, t)$
- Unsteady Free-surface Flow (Shallow water):  $h_s(x, y, t)$ ,  $u_s(x, y, t)$ ,  $v_s(x, y, t)$
- Unsteady Unconfined Aquifer Flow:  $h_g(x, y, t)$

Dr. Anirban Dhar NPTEL Computational Hydraulics 4 / 16

So if this is our ground surface and in the bottom we have water table at this level so for this system we will have surface water flow. In this case this is our  $hS$ . Now this  $hS$  is there and obviously they will be infiltration through this zone which is the ground surface or GS. And it will travel through this unsaturated zone and in the bottom we have saturated flow condition. This saturated flow condition is there for unconfined aquifer system.

For unconfined aquifer system we do not have any confining layer on top so it is directly connected to atmosphere. And unconfined aquifer system is also called as phreatic aquifer or water table aquifer.

(Refer Slide Time: 10:40)

Problem Statement

Information Transfer Mechanism Algorithm References

I.I.T. Kharagpur

$h_s(x, y, t)$   
 $u_s(x, y, t)$   
 $v_s(x, y, t)$

Unsaturated zone

Saturated Flow

Unconfined Aquifer / Phreatic Aquifer / Water Table

Required

- Unsteady Channel Flow:  $Q_c(x, t), y_c(x, t)$
- Unsteady Free-surface Flow (Shallow water):  $h_s(x, y, t), u_s(x, y, t), v_s(x, y, t)$
- Unsteady Unconfined Aquifer Flow:  $h_g(x, y, t)$

Dr. Anirban Dhar NPTEL Computational Hydraulics 4 / 16

Now in this case we have surface flow which is or this is SF or surface flow and below this water table we have GF or ground water flow which is for unconfined aquifer system. Now there will be recharge through this unsaturated zone towards this ground water table and after getting this recharge obviously we can solve this ground water equation. So for ground water problem which is unsteady unconfined aquifer flow we need to find out  $h_g$  or what is the hydraulic head with respect to datum?

(Refer Slide Time: 11:40)

Problem Statement

Information Transfer Mechanism Algorithm References

I.I.T. Kharagpur

$h_s(x, y, t)$   
 $u_s(x, y, t)$   
 $v_s(x, y, t)$

SF

Unsaturated zone

GF

Saturated Flow

Unconfined Aquifer / Phreatic Aquifer / Water Table

Required

- Unsteady Channel Flow:  $Q_c(x, t), y_c(x, t)$
- Unsteady Free-surface Flow (Shallow water):  $h_s(x, y, t), u_s(x, y, t), v_s(x, y, t)$
- Unsteady Unconfined Aquifer Flow:  $h_g(x, y, t)$

Dr. Anirban Dhar NPTEL Computational Hydraulics 4 / 16

Now we can divide it into three components. First one is channel flow so we have these are external junction points, at the same time if we have these points, these are also outlet points

or outflow points in between. And others are internal junction points. So we need a certain number of equations.

(Refer Slide Time: 12:31)

Problem Statement

**Problem Definition**  
Channel Flow

Required

- Unsteady Channel Flow:  $Q_c(x, t), y_c(x, t)$

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

Let us say in this case we have 1, 2, 3, 4, 5, then 6, 7, 8, this is 9, this one is 10, on this side we have 11, let us say this is 12, this is 13, this is 14, this is 15, 16 and 17 channel reaches in this case and we have one inflow condition. So for 17 channel reaches we have all total if we divide this one into number of reaches so for 17 if we have summation  $i$  equals to 1 to 17  $N_i$  or  $N_i$  plus 1 this is the total number of sections for  $i$ th reach.

(Refer Slide Time: 14:24)

Problem Statement

I.I.T. Kharagpur

**Problem Definition**  
Channel Flow

Required

- Unsteady Channel Flow:  $Q_c(x, t), y_c(x, t)$

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

And if we sum it up obviously we will get the total number of sections. We should multiply it with 2. That will give us the total number of unknowns because at each section we need to find out what is  $Q_c$  and  $y_c$  for this system? And  $Q_c$  and  $y_c$  these two values are functions of  $x$  and  $t$ , this is also functions of  $x$  and  $t$ . Obviously this is one unsteady channel network problem.

(Refer Slide Time: 15:04)

The slide displays a schematic of a channel network with 17 numbered nodes. Handwritten red annotations include the formula  $2 \times \sum_{i=1}^{17} (N_i + 1) = 80$  and the variables  $Q_c(x,t)$  and  $y_c(x,t)$ . A 'Required' section lists 'Unsteady Channel Flow:  $Q_c(x,t), y_c(x,t)$ '. The slide footer includes 'Dr. Anirban Dhar', 'NPTEL', and 'Computational Hydraulics'.

Depending on the upstream flow condition or upstream inflow condition there will be changes in the flow pattern and discharge within the channel network. Obviously these outlet points these points maybe through direct pipe flow or through some hydraulic structure. So we need to incorporate the effect of hydraulic structures within this system.

## Problem Definition

### Channel Flow

**Required**

- Unsteady Channel Flow:  $Q_c(x, t), y_c(x, t)$

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

But obviously in simplified form we will get junction conditions in terms of discharge or flow depth that is energy condition and we can solve the problem using our channel network flow equation and we can utilise our generalized code with reverse flow situation for this one. And this is one unsteady problem. Now next one is our conceptualization in terms of governing equation. So in this case in continuity as per our previous consideration we have  $\frac{\partial A}{\partial t}$  and  $\frac{\partial c}{\partial x}$ . This is  $\frac{\partial c}{\partial x}$ .

(Refer Slide Time: 16:53)

Problem Statement  
Information Transfer Mechanism  
Algorithm

I.I.T. Kharagpur

## Problem Definition

### Channel Flow

Governing Equation for unsteady 1D channel flow (St. Venant Equations) can be written as (Weiming, 2007).

**Initial Boundary Value Problem**

Continuity Equation:

$$\frac{\partial A}{\partial t} + \frac{\partial Q_c}{\partial x} = -q_c$$

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

So in this case one thing is important that is  $A$  is function of  $y_c$  and  $Q$  is one variable here and this minus  $Q_c$  this is important. Minus  $Q_c$  means that I am allowing outflow from the channel

network. That is there will be outflow from the channel network. So minus  $Q_c$  is the outflow component.

(Refer Slide Time: 17:23)

Problem Statement

## Problem Definition

### Channel Flow

Governing Equation for unsteady 1D channel flow (St. Venant Equations) can be written as (Weiming, 2007).

**Initial Boundary Value Problem**

Continuity Equation:

$$\frac{\partial A}{\partial t} + \frac{\partial Q_c}{\partial x} = -q_c$$

*Handwritten notes: A[y<sub>c</sub>], q<sub>c</sub>*

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

Next is momentum equation. This is the same equation that we have utilised for our unsteady channel network problem and these notations are standard ones. Yc is the depth of flow, Sf is the friction slope, this is n square Q square R to the power 4 by 3 A square, A is again cross sectional area as I have told, this is function of Yc. Qc is the lateral outflow, our negative sign is there to consider the outflow condition and H is water surface elevation which is yc plus z for any section.

Alpha is the momentum correction factor, Qc is the discharge, g is the acceleration due to gravity and z is the elevation of the channel bottom with respect to datum.

(Refer Slide Time: 18:41)

Problem Statement  
Information Transfer Mechanism  
Algorithm

## Problem Definition

### Channel Flow

Governing Equation for unsteady 1D channel flow (St. Venant Equations) can be written as (Weiming, 2007).

**Initial Boundary Value Problem**

Continuity Equation:

$$\frac{\partial A}{\partial t} + \frac{\partial Q_c}{\partial x} = -q_c$$

Momentum Equation:

$$\frac{\partial}{\partial t} \left( \frac{Q_c}{A} \right) + \frac{\partial}{\partial x} \left( \frac{\alpha Q_c^2}{2A^2} \right) + g \frac{\partial H}{\partial x} + g S_f = 0$$

where

$y_c$ = depth of flow	$H$ = water surface elevation (= $y_c + z$ )
$S_f$ = friction slope (= $\frac{n^2 Q^2}{R^{4/3} A^2}$ )	$\alpha$ = momentum correction factor
$A$ = cross-sectional area	$Q_c$ = discharge
$q_c$ = lateral outflow	$g$ = acceleration due to gravity
$z$ = elevation of the channel bottom w.r.t. datum	

Dr. Anirban Dhar      NPTEL      Computational Hydraulics      6 / 16

Now we need to consider this component and we need to link this component with the surface water because if there is lateral outflow from the channel obviously the contribution will be towards surface water flow situation which is two dimensional flow. Now in unsteady free surface flow condition which is shallow water flow condition these are inflow points or we have information about discharge values at these point or inflow values at these points for the surface water system.

With this we can start our unsteady problem and we can solve it with definite boundary conditions. Obviously we need boundary condition for this command area because we have considered this rectangular system as irrigation command.

(Refer Slide Time: 19:53)

Problem Statement  
Information Transfer Mechanism  
Algorithm

### Problem Definition

Unsteady Free-surface Flow

Required

- Unsteady Free-surface Flow (Shallow water):  $h_s(x, y, t)$ ,  $u_s(x, y, t)$ ,  $v_s(x, y, t)$

Dr. Anirban Dhar      NPTEL      Computational Hydraulics      7 / 16

Now next problem is definition of the governing equation in vector form. We can write  $\frac{\partial U}{\partial t}$ ,  $\frac{\partial E}{\partial x}$ ,  $\frac{\partial G}{\partial y}$  equals to  $S$ . And this is  $hS$ ,  $u_s$ ,  $v_s$  these are water height. This depth velocity at  $x$  and  $y$  directions and this component is important because we need to find out the linkage between channel flow and surface water flow.

(Refer Slide Time: 20:36)

Problem Statement  
Information Transfer Mechanism  
Algorithm  
References

I.I.T. Kharagpur

### Problem Definition

Unsteady Free-surface Flow

Depth-integrated mass and momentum conservation equations for surface water flow can be written as,

Governing equation

$$\frac{\partial \mathbf{U}}{\partial t} + \frac{\partial \mathbf{E}}{\partial x} + \frac{\partial \mathbf{G}}{\partial y} = \mathbf{S} \quad (1)$$

$$\mathbf{U} = \begin{bmatrix} h_s \\ h_s u_s \\ h_s v_s \end{bmatrix}, \quad \mathbf{E} = \begin{bmatrix} h_s u_s \\ h_s u_s^2 + \frac{gh_s^2}{2} \\ h_s u_s v_s \end{bmatrix}, \quad \mathbf{G} = \begin{bmatrix} h_s v_s \\ h_s u_s v_s \\ h_s v_s^2 + \frac{gh_s^2}{2} \end{bmatrix}, \quad \mathbf{S} = \begin{bmatrix} R + q_c - q_s \\ gh_s(S_{0x} - S_{fx}) \\ gh_s(S_{0y} - S_{fy}) \end{bmatrix}$$

where  $h_s$  = water height,  $u_s, v_s$  = velocity at x and y directions.

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

What is the linkage? Linkage is here, if I have rainfall component R is rainfall and plus qc which is qc is the channel outflow. So this contribution is coming from channel. R is rainfall which is occurring in the area. So R plus qc minus qs. What is this qs? Qs is the infiltration component. So we can deduct this amount to get the maximum or the total inflow to the system. This is inflow minus outflow. So effective inflow to the system is R plus qc minus qs.

(Refer Slide Time: 21:35)

### Problem Definition

Unsteady Free-surface Flow

Depth-integrated mass and momentum conservation equations for surface water flow can be written as,

Governing equation

$$\frac{\partial \mathbf{U}}{\partial t} + \frac{\partial \mathbf{E}}{\partial x} + \frac{\partial \mathbf{G}}{\partial y} = \mathbf{S} \quad (1)$$

$$\mathbf{U} = \begin{bmatrix} h_s \\ h_s u_s \\ h_s v_s \end{bmatrix}, \quad \mathbf{E} = \begin{bmatrix} h_s u_s \\ h_s u_s^2 + \frac{gh_s^2}{2} \\ h_s u_s v_s \end{bmatrix}, \quad \mathbf{G} = \begin{bmatrix} h_s v_s \\ h_s u_s v_s \\ h_s v_s^2 + \frac{gh_s^2}{2} \end{bmatrix}, \quad \mathbf{S} = \begin{bmatrix} R + q_c - q_s \\ gh_s(S_{0x} - S_{fx}) \\ gh_s(S_{0y} - S_{fy}) \end{bmatrix}$$

where  $h_s$  = water height,  $u_s, v_s$  = velocity at x and y directions.

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

Now we need to link these parameters. Out of these parameters rainfall we cannot directly link with groundwater flow system. We need another component because if there is rainfall in a particular area so total amount will not get recharged into the system. Partial or a fraction of

that will be there for infiltration. So let us say that  $q_s$  is that amount. Now we need to link this  $q_s$  with our ground water equation. So this is our unconfined unsteady aquifer flow model where we have three pumping wells, 1, 2 and 3.

(Refer Slide Time: 22:40)

The slide is titled "Problem Definition: Unsteady Unconfined Aquifer Flow". It shows a grid representing a discretized domain with three red circles containing dots, representing pumping wells. A "Required" section lists "Unsteady Unconfined Aquifer Flow:  $h_g(x, y, t)$ ". The slide is from I.I.T. Kharagpur, presented by Dr. Anirban Dhar, and is part of the NPTEL Computational Hydraulics course.

And in this case we need to find out what is  $h_g$  which is again function of  $x$ ,  $y$  and  $t$ . And we should remember that at every cell because I have discretized it into number of cells so at every cell we will have information about  $q_s$ .  $Q_s$  is the component which is coming from our or which is linking the surface water and ground water. So  $q_s$  is the amount which is coming out from the surface water system and it is getting recharged into the saturated ground water flow as saturated ground water flow component.

So obviously in this case we are considering that whatever amount is getting recharged into the system that is directly added to the ground water system. There is no loss in unsaturated zone.

(Refer Slide Time: 24:00)

Problem Statement

**Problem Definition**  
Unsteady Unconfined Aquifer Flow

9

Required

- Unsteady Unconfined Aquifer Flow:  $h_g(x, y, t)$

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

So in this case we can utilise our usual governing equation for solution. So what is that governing equation? Now I have modified this equation because we need to consider the bed elevation of the aquifer. This bed elevation component this is again function of x and y. So we are considering bed elevation with respect to a particular datum. So if I consider that this is my datum and this is the ground water table and this is my base of the aquifer then we have this is ground surface or GS.

(Refer Slide Time: 25:24)

Problem Statement  
Information Transfer  
Mechanism  
Algorithm

**Problem Definition**  
Unsteady Unconfined Aquifer Flow

**Governing equation**

In two-dimension groundwater flow in unconfined aquifer can be written as,

$$S_y \frac{\partial h_g}{\partial t} = \frac{\partial}{\partial x} \left( K_x (h_g - \xi) \frac{\partial h_g}{\partial x} \right) + \frac{\partial}{\partial y} \left( K_y (h_g - \xi) \frac{\partial h_g}{\partial y} \right) - W_p + W_I + q_s$$

where  $K_x, K_y$  = hydraulic conductivity at x and y directions  $W_I$  = injection rate,  $W_p$  = pumping rate,  $\xi$  = elevation of aquifer base.

$\zeta(z,y)$   
 $h_g(z,y,t)$   
Datum

Dr. Anirban Dhar NPTEL Computational Hydraulics 10 / 16

So in this case we need to deduct this amount for consideration of flow and other three components we have minus P, plus I and plus  $q_s$ . Plus  $q_s$  is the infiltration component which is coming from the surface water system. This component can be calculated using our standard one dimensional conceptual models or analytical models like (26:56) models. And it is minus WP is the pumping rate because we have three pumping wells in the system so we need to consider this component. And there can be injection wells in the system where we can inject water into the aquifer.

(Refer Slide Time: 27:21)

Problem Statement  
Information Transfer Mechanism  
Algorithm

I.I.T. Kharagpur

### Problem Definition

Unsteady Unconfined Aquifer Flow

**Governing equation**

In two-dimension groundwater flow in unconfined aquifer can be written as,

$$S_y \frac{\partial h_g}{\partial t} = \frac{\partial}{\partial x} \left( K_x (h_g - \xi) \frac{\partial h_g}{\partial x} \right) + \frac{\partial}{\partial y} \left( K_y (h_g - \xi) \frac{\partial h_g}{\partial y} \right) - W_p + W_I + q_s$$

where  $K_x, K_y$  = hydraulic conductivity at x and y directions  $W_I$  = injection rate,  $W_p$  = pumping rate,  $\xi$  = elevation of aquifer base.

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

So obviously in this case we are considering these three components channel flow, surface flow and ground water flow. Let us see how these components are interacting with each other? Now this is canal surface water ground water interaction case. Now we have channel network let us say this is our one particular section. This was our rectangular domain for the command area and within that let us say this is our channel system. And if I take one section there let us say this is my section A, A prime.

(Refer Slide Time: 28:50)

If I take that section I should get this view and in that section I have this canal flow on top because canal is always at a higher elevation compared to usual ground surface. This is our ground surface on both sides and we have outflow component which is coming out from the canal system which is  $q_c$  and this outflow is through pipe.

(Refer Slide Time: 29:30)

So we have linked canal flow with pipe flow Now if the water level is above this pipe inlet obviously there will be flow from left to right. If this water level is below the lower elevation of the outlet pipe then there will be no flow from left to right. That is  $q_c$ . Then  $q_c$  will be zero. Now in this case we are considering this canal flow through this outlet.

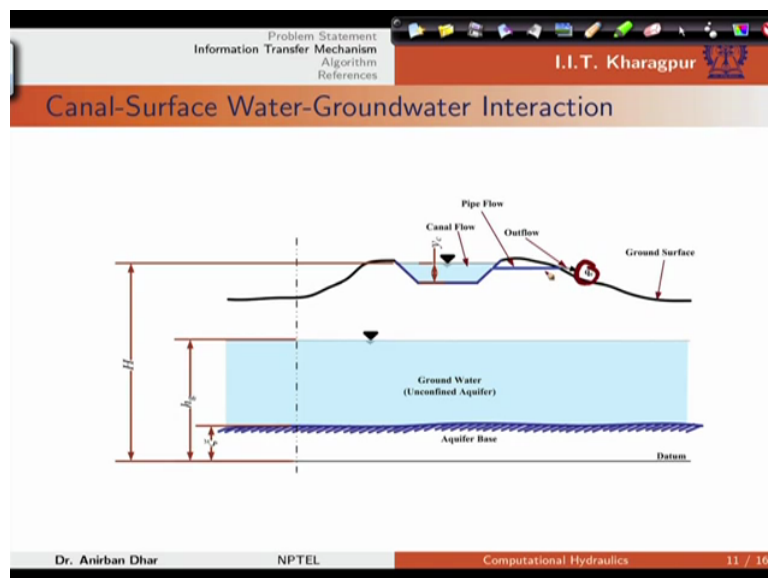

There may be situations where we have a flood situation in the right hand side then if we have surface flooding which is above this outlet but it is below this (30:50) height obviously there will be flow from right to left wards if there is difference in elevation.

(Refer Slide Time: 31:00)

So we can see that this  $q_c$  is not fixed amount. It will vary depending on the condition in the 2D system or 2D surface flooding system and 1D canal flow system. Obviously in this case we are considering that canal is line 1. So there is no outflow or infiltration from the channel bottom or canal system. Only through outflow we have this component,  $q_c$  is coming out from the system.

(Refer Slide Time: 32:01)

Now after I have got this  $q_c$  amount from our channel network we can find out what will be the surface flooding situation in the two dimensional system. So this will be the surface flooding situation. Obviously as we are considering canal flow is one dimensional or channel

flow as one dimensional. We are not considering any rainfall recharge on top of the canal. Only we will be considering this rainfall in the 2D surface flooding (sys) system.

So obviously if there is outflow from the canal there will be rise in the water table or surface in the surface flooding situation. So this is the free surface there. So we have recharge component or rainfall here and  $q_s$  is the infiltration component and  $q_c$  is inflow. So that is why  $R + q_c - q_s$  is the net inflow to the system.

(Refer Slide Time: 33:40)

Now in this case we are considering this surface water system and when we have considered our canal flow still there will be ground water flow but without recharge from the surface water system. But when we have this recharge component available  $q_s$  so we need to add this to our ground water system or which is the unconfined aquifer. In that case there will be a rise in the water table due to this recharge. Below this canal I have not considered this recharge because this is line 1 that is by conceptualization of this problem.

(Refer Slide Time: 34:47)

So in this case we need to define our values. So what are the values for our canal flow  $H$  which is water surface irrigation.  $H$  is nothing but  $y_c$  plus  $z$ . So I have not shown this  $z$  but I have shown this  $y_c$  and  $H$ . Obviously  $z$  will be  $H$  minus  $y_c$  in this case. This  $h_s$  is the surface water flow depth,  $z_D$  is the water elevation of the ground surface,  $h_g$  is the elevation of the ground water surface or (35:50) water table and in this case this is the elevation of the aquifer bottom.

(Refer Slide Time: 36:00)

So these are the different components that we need to consider in the integrated system. Obviously in this case we have linked few things or few components. One is groundwater

flow from the backward direction groundwater flow then we have surface water flow, we have pipe flow, we have channel.

(Refer Slide Time: 36:34)

In our module 3 we have discussed our discretization of the ground water flow equations. In module 4 I have discussed this canal flow or channel network flow problem, this one is module 3, module 4, module 5 is our ground surface or this also comes under module 4. This is last unit or unit 8 and this module 5 is our pipe network flow.

(Refer Slide Time: 37:30)

So we can integrate the discretization of different components from different modules and we can solve one integrated problem using our available governing equations. Now in this case we have linked this problem of 1D channel flow, pipe flow, our surface flooding and ground water flow components using recharge or discharge value. That is infiltration or outflow from the system or infiltration to the system.

But there is another way of linking this surface water and ground water flow. In this case canal is at a higher elevation but if we consider river flow situation in that case river will be at a lower elevation, river bed. Now this is our regional ground water level.

(Refer Slide Time: 39:05)

In that case this unconfined ground water table elevation should coincide with the water level or stage in the river. So we can solve this integrated surface ground water and river flow situation using our governing equations. But still in this case there can be surface flow. This surface flow may be due to rainfall. This surface flow may be due to rainfall, this  $q_s$  is the infiltration which is coming out from the surface water system.

(Refer Slide Time: 40:00)

Obviously if we have water level at higher elevation at the ground water system then there will be flow of water from ground water system towards the river. The situation is called as gaining stream situation. And if we have a losing stream situation where our water level is like this. So this is the water surface elevation.

(Refer Slide Time: 40:53)

For our ground water system obviously there will be flow from our river system towards the ground water. So this is the losing stream situation. So we can model the interaction between ground water and surface water. In previous case in the canal flow situation there will be interaction between the surface flooding situation and canal flow. Still if we have water

logging situation in the system then also there will be interaction between ground water and surface water.

But in this case this ground water system is directly linked with the river flow situation. And surface water is linked through this  $q_s$ . Obviously if there is a rise in the water table up to ground surface there will be interaction between surface flow and ground water flow. So what is algorithm structure? Data, let us say this is the information available at  $n$ th time level. So these are the values which are available at the  $n$ th time level.

## Algorithm Structure

Time-stepping

Data:  $Q_c(x, t_n)$ ,  $y_c(x, t_n)$ ,  $h_s(x, y, t_n)$ ,  $u_s(x, y, t_n)$ ,  $v_s(x, y, t_n)$ ,  $h_g(x, y, t_n)$

Dr. Anirban Dhar NPTEL Computational Hydraulics

And what is our objective? Objective is to find out the value for updated  $Q_c$  or  $x$   $t_n$  plus 1. That means at future time level what will be the value? Now what should be the structure? Structure is forward structure for the problem solve channel flow with  $\Delta t_c$  then calculate  $Q_c$  then solve surface water flow with  $\Delta t_s$  then calculate  $q_s$  because we need to use this  $q_s$  for both surface flow and ground water flow. So this solve ground water flow system with  $\Delta t_g$ .

### Algorithm Structure

Time-stepping

**Data:**  $Q_c(x, t_n), y_c(x, t_n), h_s(x, y, t_n), u_s(x, y, t_n), v_s(x, y, t_n), h_g(x, y, t_n)$   
**Result:** Updated  $Q_c(x, t_{n+1}), y_c(x, t_{n+1}), h_s(x, y, t_{n+1}), u_s(x, y, t_{n+1}), v_s(x, y, t_{n+1}), h_g(x, y, t_{n+1})$

```
while t < end time do
  Solve Channel Flow with  $\Delta t_c$ 
  Calculate  $q_c$ 
  Solve Surface Flow with  $\Delta t_s$ 
  Calculate  $q_s$ 
  Solve Groundwater Flow with  $\Delta t_g$ 
```

Dr. Anirban Dhar NPTEL Computational Hydraulics

So in this case  $q$  is required for both so we need to calculate first here and then we need to solve surface water flow and ground water flow system. So finally we need to solve this ground water system with  $\Delta t_g$  and  $n$  we should update to get the old time level value because now future time level value is old time level value or available value for the next time step. Now in this case these three things are important,  $\Delta t_c$ ,  $\Delta t_s$ ,  $\Delta t_g$ .

  Calculate  $q_c$ 
  Solve Surface Flow with  $\Delta t_s$ 
  Calculate  $q_s$ 
  Solve Groundwater Flow with  $\Delta t_g$ 
   $n \leftarrow n + 1$ 
end
```

Dr. Anirban Dhar NPTEL Computational Hydraulics

Let us say that we are utilising explicit formulation for our problem. Obviously depending on the requirement for different condition like CFL condition or other condition we need to restrict the  $\Delta t$  value. Obviously for surface water ground water interaction problem we

have this usual condition. That means  $\Delta t_c$  should be less than  $\Delta t_s$  less than  $\Delta t_g$ . So why this is happening? Because the groundwater flow is the slow process and it is a slow system.

## Algorithm Structure

### Time-stepping

**Data:**  $Q_c(x, t_n), y_c(x, t_n), h_s(x, y, t_n), u_s(x, y, t_n), v_s(x, y, t_n), h_g(x, y, t_n)$   
**Result:** Updated  $Q_c(x, t_{n+1}), y_c(x, t_{n+1}), h_s(x, y, t_{n+1}), u_s(x, y, t_{n+1}), v_s(x, y, t_{n+1}), h_g(x, y, t_{n+1})$

```

while t < end time do
  Solve Channel Flow with  $\Delta t_c$ 
  Calculate  $q_c$ 
  Solve Surface Flow with  $\Delta t_s$ 
  Calculate  $q_s$ 
  Solve Groundwater Flow with  $\Delta t_g$ 
  n ← n + 1
end

```

$\Delta t_c < \Delta t_s < \Delta t_g$

Time-Step  
 $\Delta t_c < \Delta t_s < \Delta t_g$

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

Then comes this  $\Delta t_s$  or 2D surface flooding situation and finally 1D channel flow. Obviously this channel flow is much faster compared to our surface flooding situation. So this condition will be there. So for a particular time step this  $\Delta t_g$  is more and  $\Delta t_c$  is less. Obviously for a particular time period or  $\Delta t_g$  we need to iterate our surface flow situation number of times. Again for a particular  $\Delta t_s$  or surface flow situation we need to iterate this  $\Delta t_c$  number of times so that we can match the values or transfer the values at the end of any time period.

Time-Step  
 $\Delta t_c < \Delta t_s < \Delta t_g$

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

So this is the overall structure of the algorithm. We can utilise this information from different modules and we can integrate this discretization to solve one integrated problem. Now this is one example which is much more generalized one. Let us say that we have a reservoir inflow system. This is one reservoir there, this is another reservoir system on this side.

## 1D-2D Integrated System

(a) Integrated 1D-2D simulations with lateral and flow direction connections (Blade et al., 2012)

(b) Discretization of computational domain

Dr. Anirban Dhar      NPTEL      Computational Hydraulics

And we have this command area system available here. So flow is coming from there. This is 1D flow to the system. Again when water will be transferred to the command area so this is 2D flow. Again at this point it is 1D and it is coming to the downstream 2D flooding area or area of our concern because if we discretize the total domain the computational effort will be much more.

So we can conceptualize different components of the system in terms of 1D and 2D systems and we can integrate those systems to solve a particular integrated problem.

(Refer Slide Time: 48:22)

The slide is titled "1D-2D Integrated System" and is from I.I.T. Kharagpur. It features a navigation bar at the top with "Problem Statement", "Information Transfer Mechanism", "Algorithm", and "References". Below the title, there are two diagrams. Diagram (a) shows a network of channels with 1D and 2D simulation regions. Diagram (b) shows a discretized domain with a red outline and a small inset showing a triangular mesh. The slide footer includes "Dr. Anirban Dhar", "NPTEL", and "Computational Hydraulics".

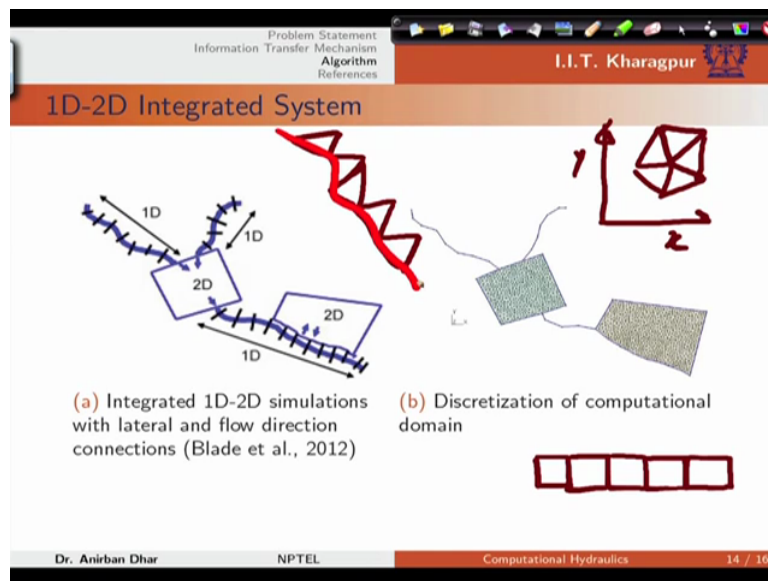

And this is discretization of the computational domain. Obviously we have only talked about the discretization in terms of rectangular gridding system which is according to the (48:47) coordinate system. But still with the (48:51) coordinate system itself we can use triangular mesh on quadrilateral mesh to divide the same domain into number of elements.

(Refer Slide Time: 49:06)

This slide is similar to the previous one, titled "1D-2D Integrated System" from I.I.T. Kharagpur. Diagram (a) is identical. Diagram (b) shows the same discretized domain but with a red outline and a small inset showing a triangular mesh. Below diagram (b), there is a red outline of a rectangular grid. The slide footer includes "Dr. Anirban Dhar", "NPTEL", "Computational Hydraulics", and "14 / 16".

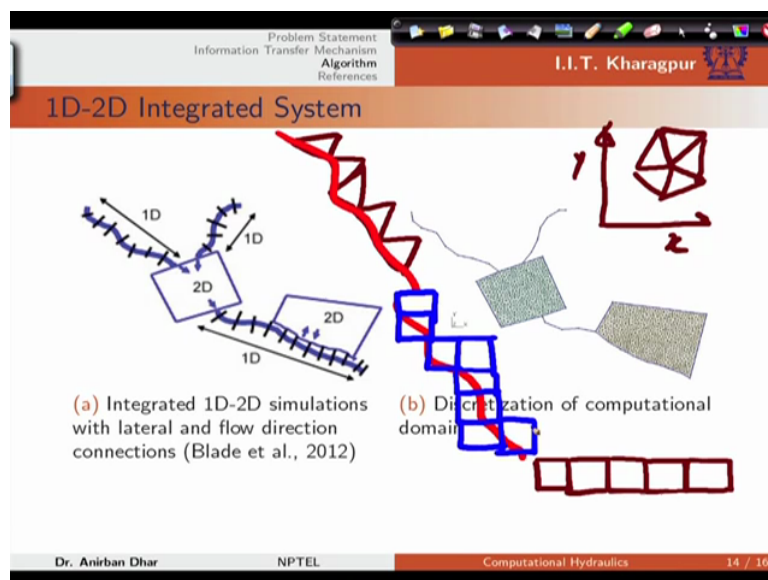

So what is the advantage of that? Advantage is that we can easily track the irregular boundaries. Near irregular boundaries this discretization is much better compared to our conventional rectangular gridding system. If this is our boundary let us say this is our boundary.

(Refer Slide Time: 49:40)

For same boundary if I want to utilise a rectangular gridding system then I need to include certain number of cells and I need to omit certain number of cells. So we cannot exactly track the boundary using or irregular boundary using our usual rectangular gridding system.

(Refer Slide Time: 50:26)

Obviously in that case we need to use this triangle meshes. So this is our overall idea about the integrated solution of the problem considering different components, it can be channel flow, it can be surface water flow, it can be ground water flow. Now we can integrate all components and we can solve this system using this integrated approach. Thank you.
