Module 7
Compressive strength of double angles

Now I will be discussing about the design compressive strength of a double angles section. Now double angles section is oftenly used because may cases appear when the single angle is not capable of taking that much load and also in case of single angle the radius of gyration about the minor axis is very low compared to its X axis, or Y axis, or major axis. Therefore as radius of gyration is quite low about in minor axis, so strength of the angle section is quite low because it may buckle through its minor axis about its minor axis.

And because radius of gyration if it is low then slenderness ratio will be high and slenderness ratio high means the design compressive stress will be less and therefore the design strength of the member will be less. Therefore with the given load sometimes we go for double angle section again double angle section may be placed it is back to back with gusset plate means gusset plate in in its two side two angle section can be provided or in the same side also in the same side of gusset plate angle sections can be provided. So this is how one can place the angle sections to make double angle section.

(Refer Slide Time: 2:15)

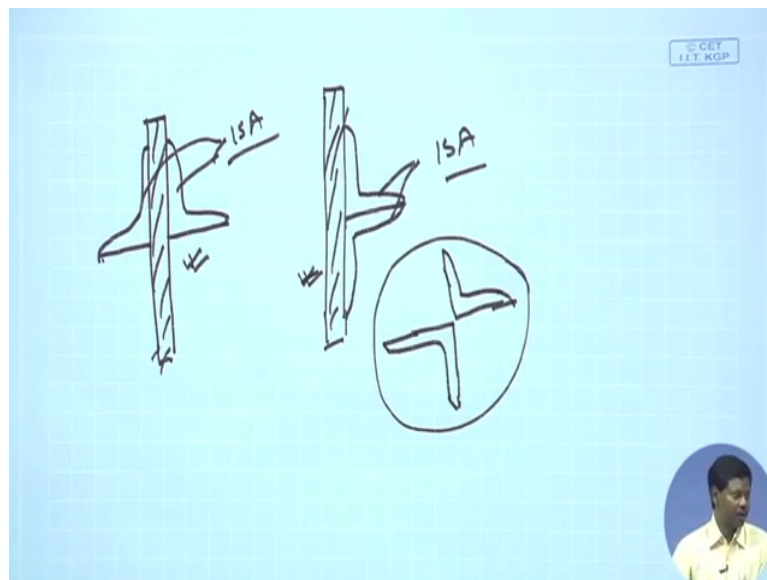

Now to know the design strength of the angle section we need to know what is the effective length of the double angles will come into come, that is given in clause 7.5.2, right the effective length of double angle struts in clause 7.5.2. So here we can see that the codal provision says that the effective length KL , in the plane of end gusset shall be taken as between 0.7 and 0.85 times the distance between the intersections, that means 0.7 to 0.85 times the L depending on the degree of restraint provided.

So depending on the degree of restraint provided the effective length will be consider as 0.7 to 0.85 times the distance between intersections and the effective length KL , in the plane perpendicular to that of the end gusset shall be taken as equal to the distance between centre of intersections. That means here K value will be 1, so this is what the codal provision says.

So when we will be going to calculate the strength of a double angle section we need means we have to follow this codal provision 7.5.2 to find out the effective length and therefore the radius of sorry slenderness ratio and then compressive stress, the allowable compressive stress. Therefore we have to know the effective length of the double angle section means whether it is according to the degree of restraint means whether the length is in the plane perpendicular to that of end gusset or other one.

(Refer Slide Time: 4:02)

So angle sections may be provided like this, say suppose two angle sections I want to provide. Now that may be possible if I use two angle section on the opposite side of gusset plate, this is one way we can make, this is gusset plate, right otherwise we can arrange the angle sections as like this also that means in same side of the gusset plate this will be. So this

is the gusset plate and we are providing two angle sections this is ISA some ISA in a single angle we can provide, right.

Also the two angles can be provided in a in this fashion also however it depends on the requirement means what type of architectural requirement is there depending on that also we can provide such type of double angle section. And also we will see if I provide angle section opposite side to the gusset plate and same side of the gusset plate then what will be the strength that means whether if I arrange in these ways strength will be more or if I arrange in this way strength will be more that also we can through one workout example we can compare.

(Refer Slide Time: 6:03)

Example: A discontinuous strut of length 4 m consists of two unequal angles ISA 100×75×8 and is connected to a 10 mm thick gusset plate by its longer leg. Determine the strength if it is connected on the:

- Opposite side of the gusset plate
- Same side of the gusset plate

Solution:

Properties of ISA 100×75×8 : [Table IV, SP:6(1)-1964]

$A = 1336 \text{ mm}^2$	}	$r_y = 21.8 \text{ mm}$
$r_x = 31.4 \text{ mm}$		$r_v = 15.9 \text{ mm}$
$r_u = 34.8 \text{ mm}$		$C_y = 18.7 \text{ mm}$
$C_x = 31.0 \text{ mm}$		$I_y = 63.3 \times 10^4 \text{ mm}^4$
$I_x = 131.6 \times 10^4 \text{ mm}^4$		

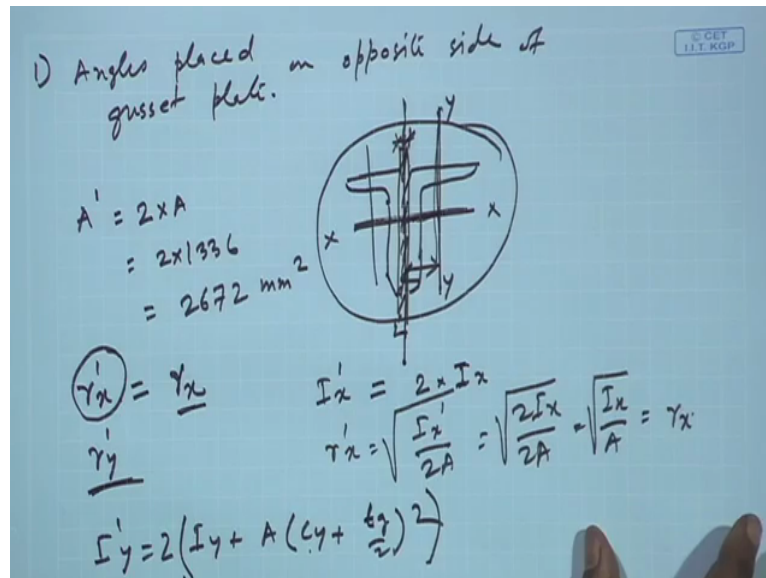

So let us go to one example which is given as this that is an discontinuous strut of length 4 meter consists of two unequal ISA ISA 100 by 75 by 8 and it is connected to a 10 mm gusset plate by its longer leg. So longer leg is connected to the gusset plate and thickness of gusset plate is 10 mm and size of angle is ISA 100 by 75 by 8. Now find the strength if it is connected on the opposite side of the gusset plate and same side of gusset plate.

So here we will compare the results using these two orientations one is opposite side of the gusset plate and another is same side of the gusset plate and we will see which one is taking more load, right.

Now properties of the single angle section can be found from table 4 of SP: 6-1964, where the cross sectional area is given r_x , r_y , r_u , r_v these are given then C_x , C_y and I_x , I_y are given and these are the properties which will be required to find out the equivalent properties of the

section equivalent properties of the section means what is the combined gross area of the section, what will be the radius of gyration minimum radius of gyration of the section, what will be the Cg of the section, so all these things we can find out from these properties and according to the orientation according to the placement of the gusset plate and angle we can find out its strength.

(Refer Slide Time: 8:12)

Now let us first come to the case where angles are placed on opposite side of the gusset plate that means we can consider that a plate a gusset plate is there and it is in its opposite side one angle is placed with its longer side longer leg and another angle of same size are placed in other side, so this will be the arrangement, this is the gusset plate, right. Now we have to find out the combined properties, like the area of the double angle say I can say A dash A dash will be 2 into area that means 2 into I got 1336, so this will be 2672 millimetre square.

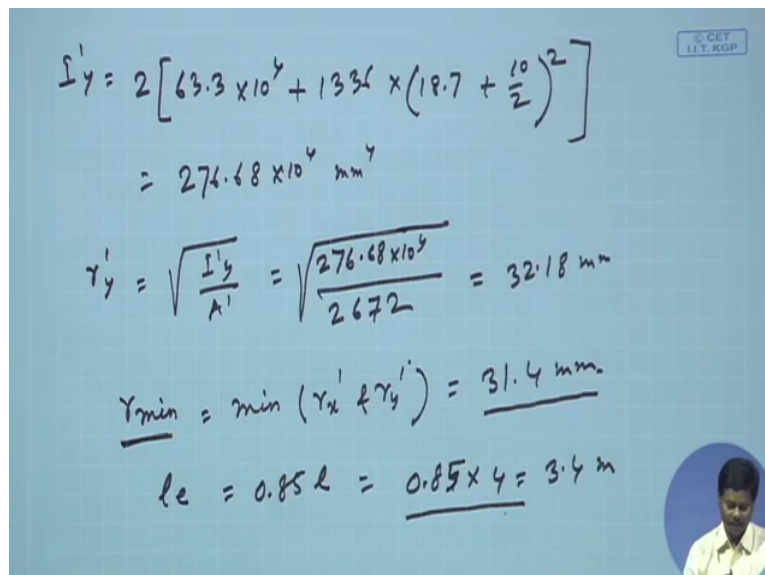

Similarly I can find out the value of r_x and r_y , that means r_x dash x and r_y dash y , so first let us find out r_x dash x , r_x dash x when we are going to find out that r_x dash x means we can find out in this direction, this is $x-x$. So to find out r_x dash x first I have to find out I_x dash that means moment of inertia about $x-x$ direction of the combined section. So that will be 2 into I_x means 2 into moment of inertia of the individual section because I_x will be in this same in same Cg distance means Cg it will it will buckle, so I_x will be same.

So I can find out r_x dash x as I_x dash by $2A$, so $2I_x$ by $2A$ that means I_x by A that means I can find out sorry this will be square root of this so root of I_x by A so r_x , that means the r_x dash x

dash value will become simply rx. So in this way means in this arrangement if we use then we cannot increase the rx value or r dash x value, right. So rx value is constant, only we can increase the value of r dash y by changing the gusset plate thickness.

Now let us see how the r dash y value is going to be calculated, so for that we have to calculate first I dash y, I dash y will be I dash y means in this direction, so I dash y will be I_y this is y-y, I_y about this axis plus $A r^2$ square, so I_y plus A into C_y plus t_g by 2 whole square, right. So I dash y about this axis will be I_y plus A into C_y square, C_y square means C_y plus t_g by 2, right and into 2 because two angles are there, so for this also it will be same so it will be added, so I dash y can be found like this, right.

(Refer Slide Time: 12:50)

$$I_y' = 2 \left[63.3 \times 10^4 + 1336 \times \left(18.7 + \frac{10}{2} \right)^2 \right]$$

$$= 276.68 \times 10^4 \text{ mm}^4$$

$$r_y' = \sqrt{\frac{I_y'}{A'}} = \sqrt{\frac{276.68 \times 10^4}{2672}} = 32.18 \text{ mm}$$

$$r_{\min} = \min(r_x', r_y') = 31.4 \text{ mm}$$

$$l_e = 0.85 L = 0.85 \times 4 = 3.4 \text{ m}$$

So if I calculate the I dash y value, I can find this as 2 into 63.3 into 10 to the power 4 which is I_y value plus A was 1336 into 18.7 plus 10 by 2 thickness of gusset plate is 10, so 10 by 2 like this. So I dash y I can find out 276.68 into 10 to the power 4 millimetre to the 4. Now once I calculate I dash y, I can find out the value of r dash y also, r dash y will be simply I dash y by A dash, so here I dash y value we have calculated as 276.68 into 10 to the power 4, A dash is basically 2 into A that is 2672, 1336 into 2, so this is becoming 32.18 millimetre.

So minimum radius of gyration r minimum I have to find out because about which it will buckle, so that will be minimum of rx dash and ry dash, right so minimum if will see it will be 31.4 millimetre, right this radius of gyration minimum radius of gyration we could found we could find as 31.4 millimetre.

Now to value the effective length l_e can be found as $0.85l$, so this will be 0.85 into it was 4 meter so this is 3.4 meter. So as per clause 7.5.2.1 I can find out the value of effective length as 0.85 into l that is 3.4 meter.

(Refer Slide Time: 15:22)

$$\lambda = \frac{l_e}{r_{\min}} = \frac{3.4 \times 1000}{31.4} = 108.28 < 180$$

Buckling class — C_1 Table-10

Table 9(c)

$$f_{cd} = 107 - \left(\frac{107 - 94.6}{10} \right) \times 8.28$$

$$= 96.73 \text{ MPa}$$

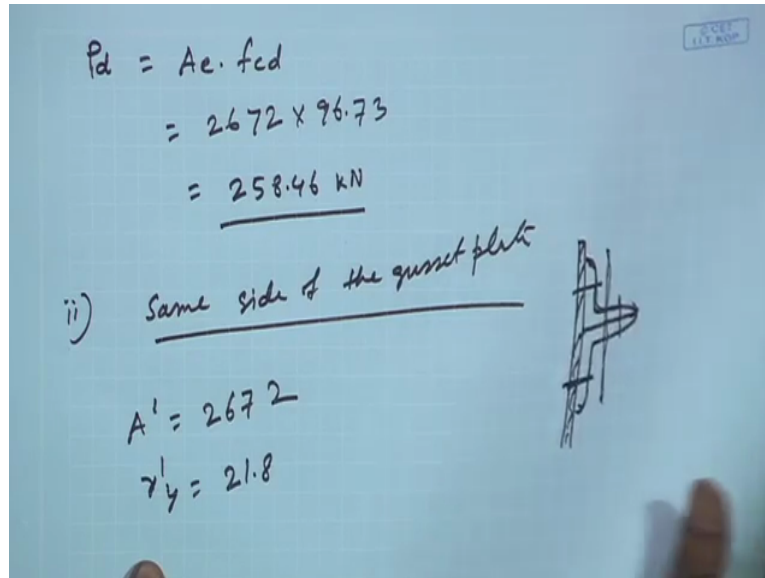

So now I can find out the value of slenderness ratio, so λ slenderness ratio I can find out l_e by r minimum that will be become 3.4 into 1000 to make it millimetre by 31.4 this is becoming 108.28 , right and this is less than 180 so it is okay as per table 3 it should be less than the permissible slenderness ratio. So λ value the slenderness ratio value we can find as 108.28 .

Now for angle section or for built-up section we know buckling class will be C buckling class of the section will be C from table 10 we can find out from table 10 I can find out the buckling class as table C and then I can find out the value of f_{cd} . Now if we use table 9c table 9c to find out value of f_{cd} f_{cd} either I can find out from the formula which are expressed in the code otherwise I can find the value from table 9c table 9 has been given to find out the value means for different value of slenderness ratio f_{cd} value has been given for different grade of steel.

So this f_{cd} value are given in table 9 a, b, c, d for class a, b, c, d. Now as this is the class C buckling class C, so we are using table 9c directly and if we use table 9c we can see that f_{cd} value will be 107 minus 107 minus 94.6 by 10 into 8.28 , this 107 is correspondent to 100 λ 100 and this correspondent to λ as 110 , for λ 110 this is 94.6 and for

lambda 100 it is 107. So if I interpolate for 108.28 I can find out the value of f_{cd} as 96.73 MPa. So f_{cd} value can be found from table 9c as 96.73 MPa.

(Refer Slide Time: 18:34)

Handwritten calculations on a grid background:

$$P_d = A_e \cdot f_{cd}$$

$$= 2672 \times 96.73$$

$$= \underline{258.46 \text{ kN}}$$

ii) Same side of the gusset plate

$$A' = 2672$$

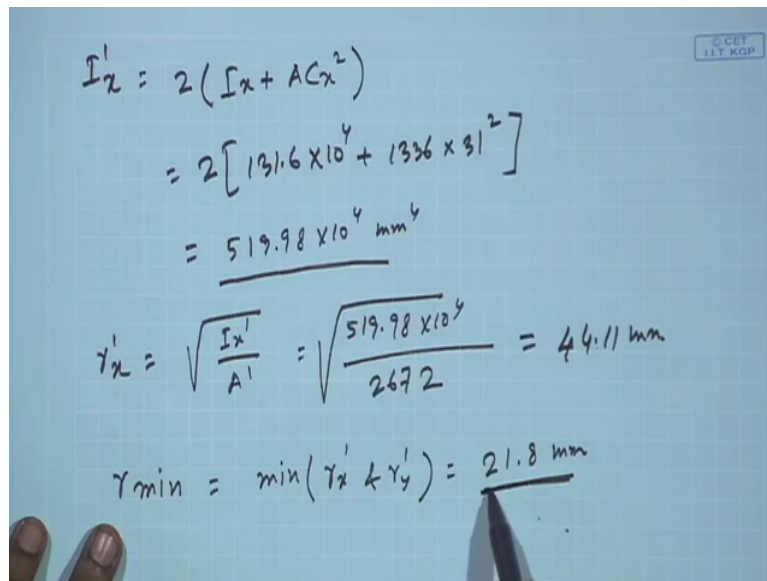

$$r'_y = 21.8$$

To the right of the text is a hand-drawn sketch of an angle section connected to a vertical line representing a gusset plate. The angle is connected to the gusset plate on the same side of its own back-to-back legs.

Now the strength design strength of the member now I can find out that will be A_e into f_{cd} , so if I put those value of A_e and into f_{cd} , A_e is 2672 which is the area of two angle section into 96.73 is the f_{cd} value. So this will become 258.46 kilonewton, right. So design strength of the member can be found as 258.46 kilonewton.

Now let us come to the second case second case is angle placed on same side of the gusset plate same side of the gusset plate. So if we use same side of the gusset plate then it will be something like this, say this is gusset plate and angle is connected through the same side of the gusset plate like this, right. So so for this case several things will be similar like A dash the gross area of the combined section will be same that will be 2672 and here r dash y will be same 21.8 which was considered earlier, r dash y means along this because r dash y , r_y of the single section whatever it is coming r dash y will be same because the C_g is not going to be changed but r dash x will be going to change.

(Refer Slide Time: 20:38)

The image shows handwritten mathematical calculations on a blue grid background. The calculations are as follows:

$$I'_x = 2(I_x + AC_x^2)$$
$$= 2[131.6 \times 10^4 + 1336 \times 31^2]$$
$$= 519.98 \times 10^4 \text{ mm}^4$$
$$r'_x = \sqrt{\frac{I'_x}{A'}} = \sqrt{\frac{519.98 \times 10^4}{2672}} = 44.11 \text{ mm}$$
$$r_{\min} = \min(r'_x \& r'_y) = 21.8 \text{ mm}$$

So we have to calculate the value of r'_x to find out r'_x , I have to find out I'_x . I'_x will be $2 I_x$ plus A into C_x square, so if I put the value of I_x as 131.6 into 10 to the power 4 plus 1336 into C_x square is 31 square. So I_x means I'_x value is becoming 519.98 into 10 to the power 4 millimetre to the power 4 . So moment of inertia of the gross section about x - x direction I am getting as this.

Now r'_x can be found that will be I'_x dash by A dash I'_x dash we got as 519.98 into 10 to the power 4 by A dash is 2672 . So after calculating the value is coming 44.11 , right. So now I can find out the value of r_{\min} , so r_{\min} will be the minimum of r'_x dash and r'_y dash, so this is becoming 21.8 mm, right. Now if we remember in earlier case r_{\min} was the r_x and here r_{\min} is the r_y , right.

(Refer Slide Time: 22:36)

$$l_e = 0.85l = 3.4 \text{ m.}$$
$$\lambda = \frac{l_e}{r_{\min}} = \frac{3.4 \times 10^3}{21.8} = 155.96 < 180$$
$$\begin{array}{l} \text{9(c)} \\ f_{cd} = 59.2 - \left(\frac{59.2 - 53.3}{10} \right) \times 5.96 \\ = 55.68 \text{ MPa} \\ P_d = 2672 \times 55.68 = 148.78 \text{ kN} \end{array}$$

Now let us come to effective length so effective length will be same for this case also l_e will be 0.85l, so 3.4 meter and λ I can find out slenderness ratio as l_e by r , r means r minimum, so this will become 3.4 into 10 cube to make it millimetre by r minimum is 21.8, so this is becoming 155.96 newton per millimetre square which is less than 180, right. So this is okay, from slenderness ratio point of view it is okay.

Now this will be buckling class C as similar to earlier case and we can use table 9c of IS 800, then I can find out the value of f_{cd} as 59.2 minus 59.2 minus 53.3 by 10 into 5.96. So this I can find as 55.68 MPa, here the value 59.2 is coming for λ is equal to 150 and 53.3 is coming for λ is equal to 160, so we are interpolating between 150 and 160 to find the value of f_{cd} at a λ of 155.96 which we are getting as this. So the design strength I can find out P_d as A_e will be same 2672 into f_{cd} value is 55.68, this is coming 148.78 kilonewton, right.

(Refer Slide Time: 24:50)

So what we could see that for first case when opposite sides of the gusset plate angles are placed opposite side to gusset plate we got 258.46 kilonewton and for second case we are getting 148.78 kilonewton, this is when angles are placed opposite side of gusset plate, here angles are placed same side of the gusset plate, so this is the difference, right. So what we could see for the same angle if it is placed opposite side to the gusset plate its strength is quite high compared to this that means we will try to prefer always the angles to be placed opposite side of the gusset plate. So that the strength can be achieved more compared to the earlier case means other case other case means when angles are placed same side of the gusset plate, right. So with this I like to conclude today's lecture, thank you.
