

Course on Design of Steel Structures
Professor Damodar Maity
Department of Civil Engineering
Indian Institute of Technology Kharagpur
Lecture 55
Module 11
Design of Purlins

This lecture will cover a workout example on design of purlin, in last lecture we have discussed about the design procedure of purlin members for both channel sections and angle sections, channel or I sections and angle sections. So here we will go through one example and we will try to understand how to design a member using channel section sorry using I sections because because of shortage of time we will not go through channel section we will have to do lot of calculation for that, so if we understand the design calculation of I section we can similarly find out for channel section. So using an example of I sections we will try to demonstrate the example.

(Refer Slide Time: 1:12)

Example: Design an I-section purlin, for an industrial building situated in the outskirts of Kolkata, to support a galvanized iron sheet roof for the following data:

- Slope of truss = 30°*
- Spacing of truss c/c = 5.0 m*
- Span of truss = 12.0 m*
- spacing of purlins c/c = 2 m*
- wind speed = 50 m/s*
- Weight of galvanized sheets = 120 N/m^2*
- Grade of steel = $\text{Fe } 410$*

Now here example is like this that we need to design an I section purlin for industrial building situated in the outskirts of Kolkata to support galvanized iron sheet roof for the following data. So datas are given like slope of the truss is 30 degree, spacing of the truss is 5 meter that means the length of the purlin is 5 meter, span of the truss is 12 meter and spacing of purlin is 2 meter that means if we draw so we are using purlin in some places, right so this will be 2 meter, right this is 2 meter and span of truss is 12 meter, right.

And in this direction the purlin if we see in this direction these purlins are length are 5 meter. Wind speed in Kolkata we can assume as 50 meter per second and weight of galvanized sheet is given as 120 newton per meter square and grade of steel as Fe 410. So with this data we need to design a I section purlin.

(Refer Slide Time: 2:57)

So considering this data let us try with the design of the purlin section say for Fe 410 grade of steel fy we know that is 250 by 250 MPa and weight of galvanized corrugated iron sheet was 120 newton per meter square 120 newton per meter square the weight that means if we have spacing of purlin is 2 meter then the weight per meter length will be 120 into 2 so 240 newton per meter, okay.

Also we can assume some dead load of the purlin say 100 newton per meter, okay. So total dead load total dead load we can consider as 340 newton per meter and that is acting vertically downward, okay which is P dash P, right. So total dead load acting vertically downward is 340 newton per meter and it has two components if we consider the truss member as like this so purlins are provided in different places say we have provided here, provided here like this, right so load is total dead load is 340, right.

So it has one component perpendicular to the roof, another component parallel to the roof, right. So dead load perpendicular to the roof we can calculate dead load perpendicular to the roof will be $340 \cos 30$ because angle is 30 degree this is 30 degree slope is 30 degree. So this will become 294.5 newton per meter and similarly so this is dead load normal to the roof say y and dead load (normal) parallel to the roof say x or I should say not y

because normal to the roof means say v and this is u so that will be $340 \sin \theta$, this is becoming 170 newton per meter.

So if we have an I section with an angle of 30 degree is placed then we have a load in this direction and we have a load in this direction, right. So in this direction is 170 and in this direction it is 294.5 this is due to dead load and also wind load is acting and as the wind speed is 50 meter, so we can find out wind pressure wind pressure will be calculated as $0.6 V_z^2$ so this will be 0.6×50^2 , this is becoming 1500 newton per meter square, right. So wind load will become means per meter wind load will become 1500 into 2, so that will be because 2 meter center to center distance it was so 3000 newton per meter, right.

So and it has been assumed that the wind is flowing perpendicular to the roof so wind is acting perpendicular to the roof also wind is acting perpendicular to the roof, right so this wind load is also will act on this direction that is 300 newton per meter. So factored means total load will be how much total load total load on purlin normal to roof normal to roof one is parallel to roof, another is normal to roof that will be 3000 plus 294.5, so this will become 3294.5 newton per meter, right so this is what the load will be.

(Refer Slide Time: 8:23)

$$\begin{aligned}
 P &= 1.5 \times 3294.5 = 4941.75 \text{ N/m} \\
 H &= 1.5 \times 170 = 255 \text{ N/m} \\
 M_{ux} = M_z &= \frac{PL}{10} = \frac{(4941.75 \times 5) \times 5 \times 10^{-3}}{10} = 12.35 \text{ kNm} \\
 M_{yy} = M_y &= \frac{HL}{10} = \frac{(255 \times 5) \times 5 \times 10^{-3}}{10} = 0.6375 \text{ kNm} \\
 z_{p_z, reqd} &= M_z \cdot \frac{y_{mo}}{f_y} + 2.5 \left(\frac{d}{6} \right) M_y \cdot \frac{y_{mo}}{f_y} \left\{ \begin{array}{l} d = 125 \\ b_f = 75 \end{array} \right\} \\
 &= 12.35 \times 10^3 \times \frac{1.1}{250} + 2.5 \times \left(\frac{125}{6} \right) \times 0.6375 \times \frac{1.1}{250}
 \end{aligned}$$

$$\begin{aligned}
 H &= 1.5 \times 170 = 255 \text{ N/m} \\
 M_{ux} = M_z &= \frac{PL}{10} = \frac{(4941.75 \times 5) \times 5 \times 10^{-3}}{10} = 12.35 \text{ kNm} \\
 M_{vy} = M_y &= \frac{HL}{10} = \frac{(255 \times 5) \times 5 \times 10^{-3}}{10} = 0.6375 \text{ kNm} \\
 Z_{pz, reqd} &= M_z \cdot \frac{\gamma_{m0}}{f_y} + 2.5 \left(\frac{d}{b} \right) M_y \cdot \frac{\gamma_{m0}}{f_y} \left\{ \begin{array}{l} d=125 \\ b=75 \end{array} \right\} \\
 &= 12.35 \times 10^6 \times \frac{1.1}{250} + 2.5 \times \left(\frac{125}{75} \right) \times 0.6375 \times \frac{1.1}{250} \\
 &= 66 \times 10^3 \text{ mm}^3
 \end{aligned}$$

So we can now find out the factored load normal to the roof say P as 1.5 into 3294.5, this will become 4941.75 newton per meter. Similarly factor load parallel to roof that will be denoted as H it will be 1.5 into 170 so 255 newton per meter, okay. So from this I can find out maximum bending moment, right so maximum bending moment say Muu or Mz we can say either we can say Mz or in this purlin axis we can say Muu that will be PL by 10 that means 4941.75 into 5 that is P total load into L because length is 5 meter by 10, this is meter and newton newton means if we make it kilonewton then I can find 12.35 kilonewton meter, right.

Similarly Mvv we can find out Mvv will be we can say also My, HL by 10 so H was 255 into 5 total horizontal load into into we can consider 5 into 10 to the power minus 3 by 10, okay. So this will be 0.6375 kilonewton meter okay. So Muu and Mvv we obtained. Now we have to find out a approximate section that we can find out from the Gaylord equation that is Zpz required that we know Mz into gamma m0 by fy plus 2.5 d by b into My into gamma m0 by fy, okay.

Now to calculate Zpz required all the values of this parameters are known except d by b so here we can assume certain depth say we assume d is equal to 125 and b as width of flange as 75, so with this assumptions we can find out the value. So if we put the values Mz as 12.35 kilonewton meter means we can make it newton millimetre with multiplication of 10 to the power 6 into 1.1 by (10) 250 plus 2.5 into 125 by 75 this is absolutely approximate one, My we have 0.6375 into 1.1 by 250, so this is how the Zpz required can be found as 66 into 10 cube millimetre cube, okay.

(Refer Slide Time: 12:35)

Handwritten calculations for ISLB 150 section properties:

$$\begin{aligned} \text{ISLB 150} \\ Z_{p2} &= 104.5 \times 10^3 \text{ mm}^3 \\ A &= 1808 \text{ mm}^2 \\ D &= 150 \\ b_f &= 80 \\ t_f &= 6.8 \\ t_w &= 4.8 \\ R_1 &= 9.5 \\ d &= D - 2(t_f + R_1) \\ &= 150 - 2(6.8 + 9.5) = 117.4 \text{ mm} \\ I_z &= 688.2 \times 10^4 \text{ mm}^4 \\ I_y &= 55.2 \times 10^4 \text{ mm}^4 \\ Z_{e2} &= 91.8 \times 10^3 \text{ mm}^3 \\ Z_{ey} &= 13.8 \times 10^3 \text{ mm}^3 \end{aligned}$$

So on the basis of this approximate plastic section modulus we can choose a section. So if we choose a section of ISLB 150 from the SP 6 we can choose a section in which the section modulus is more than the required one. So plastic section modulus of this ISLB 150 is 104.5 into 10 cube and we need to have 66 into 10 cube millimetre cube, right. And from SP 6 we can find out the cross-sectional area as 1808 which will be required. So this data we can find out like depth is 150, width of flange is 80, thickness of flange is 6.8, thickness of web is 4.8 and root radius R_1 is 9.5, right.

Also we can find out the value of d effective depth that is we know d minus 2 into t_f plus R_1 , so if we put this value we can find out the value of effective depth as 117.4 millimetre, right. Now we can find out also we can find out the value of I_z as 688.2 into 10 to the power 4 millimetre to the power 4 from the SP 6. Similarly I_y as 55.2 into 10 to the power 4 millimetre to the power 4 and Z_{e2} the elastic section modulus is equal to 91.8 into 10 cube millimetre cube and Z_{ey} 13.8 into 10 cube millimetre cube, right. So we have all these data for ISLB 150.

(Refer Slide Time: 15:10)

Handwritten calculations on a whiteboard:

$$\epsilon = \sqrt{\frac{250}{fy}} = 1$$

$$\frac{b}{tf} = \frac{40}{6.8} = 5.88 < 9.4$$

$$\frac{d}{tw} = \frac{117.4}{4.8} = 24.5 < 84$$

plastic

$$Mdz = \frac{Z_{pz} \times fy}{\gamma_{m0}} = \frac{104.5 \times 10^3 \times \frac{250}{1.1} \times 10^{-6}}{1.1} = 23.75 \text{ kNm}$$

$$< 1.2 \frac{Z_{ez}}{\gamma_{m0}} = 1.2 \times 91.8 \times 10^3 \times \frac{250}{1.1} \times 10^{-6} = 25.04 \text{ kNm}$$

12.35 kNm OK

Now we need to know the section type so to classify the section we need to know b by t_f ratio and d by t_w and also epsilon we know that is 250 by f_y so here it will be 1 and b by t_f will be b was b_f was 80 so b will be 80 by 2 that is 40 and t_f was given as 6.8 so it is 5.88 less than 9.4 and d by t_w d we have considered as 117.4 while t_w is 4.8 so 24.5 and less than 84 . So from this we can say that the section is plastic, right. So section is classified as plastic.

Now we have to check for bending strength, so bending strength we can calculate that is M_{dz} as Z_{pz} into f_y by γ_{m0} Z_{pz} value was taken as 104.5 into 10 cube into f_y is 250 by γ_{m0} is 1.1 and to make it kilonewton meter we can multiply as 10 to the power minus 6 , so this is becoming 23.75 kilonewton meter, right and it should be less than as we know $1.2 Z_{ez}$ by γ_{m0} . So that if we calculate we can see that is 1.2 into 91.8 into 10 cube into 250 by 1.1 is equal to 25.04 kilonewton, okay. So M_{dz} value is coming this which should be less than this so it is okay.

Maximum moment M_z was 12.35 , so it is okay. So the design bending strength M_{dz} was calculated as 23.75 kilonewton meter and the bending moment about z - z axis is coming 12.35 kilonewton which is less than the design bending strength so it is okay, if it is not okay then we need to increase the section size, right.

(Refer Slide Time: 17:59)

$$M_{dy} = \frac{Z_{py} \times f_y}{\gamma_{m0}}$$

$$Z_{py} = \left(\frac{b_f}{2} \times t_f \times \frac{b_f}{4} \right) \times 4 + (D - 2t_f) \times \frac{t_w}{2} \times \frac{t_w}{4} \times 2$$

$$= \frac{t_f b_f^2}{2} + \frac{(D - 2t_f) t_w^2}{4} = \frac{6.8 \times 80^2}{2} + \frac{(150 - 2 \times 6.8) \times 4.8}{4}$$

$$= 22546 \text{ mm}^3$$

$$\rightarrow M_{dy} = 22546 \times \frac{250}{1.1} \times 10^{-6} = 5.12 \text{ kNm}$$

$$Z_{py} = \left(\frac{b_f}{2} \times t_f \times \frac{b_f}{4} \right) \times 4 + (D - 2t_f) \times \frac{t_w}{2} \times \frac{t_w}{4} \times 2$$

$$= \frac{t_f b_f^2}{2} + \frac{(D - 2t_f) t_w^2}{4} = \frac{6.8 \times 80^2}{2} + \frac{(150 - 2 \times 6.8) \times 4.8}{4}$$

$$= 22546 \text{ mm}^3$$

$$\rightarrow M_{dy} = 22546 \times \frac{250}{1.1} \times 10^{-6} = 5.12 \text{ kNm}$$

$$M_p = 1.5 \times 13.8 \times 10^3 \times \frac{250}{1.1} \times 10^{-6} = 4.7 \text{ kNm}$$

$$Z_{py} = 1.6 \times 10^6 \text{ mm}^3$$

So next will calculate the M_{dy} value, right to calculate M_{dy} value we need to know say M_{dy} is equal to Z_{py} into f_y by γ_{m0} . So we need to know the value of Z_{py} , right. So Z_{py} we can calculate from the formula the Z_{py} is the section modulus along y-y, so Z_{py} we know for a I section we can calculate the Z_{py} value in this way that is the cg will pass through middle of the section so here we will calculate this portion into 4 that means that will be Z_{py} is equal to b_f by 2 into t_f into b_f by 4 into 4, right. So area into cg distance area is this and cg distance is b_f by 4 into 4 plus D minus $2t_f$ this portion this portion will be this so D minus $2t_f$ into t_w by 2 into cg distance that will be t_w by 4 into 2 side so into 2.

So finally it will become t_f into b_f square by 2 plus D minus $2t_f$ into t_w square by 4 and if we put the values of these parameters we can see that (b_f) t_f is 6.8, b_f is 80, then overall depth is

150 and thickness of flange is 6.8 and width of the web is 4.8, right. So this is becoming 22546 millimetre cube. So now we can find out the value of M_{dy} , right so M_{dy} will become 22546 that is Z_{py} into f_y by γ_{m0} so into 10 to the minus 6, so this is becoming 5.12 kilonewton meter.

And it should be less than 1.2 into Z_{ey} into f_y by γ_{m0} , so here 1.2 will be replaced by 1.5 why I am coming so 1.5 into Z_{ez} was Z_{ey} was 13.8 into 10 cube into f_y by γ_{m0} into 10 to the power minus 6 is equal to 4.7. Because here we have consider in place of 1.2 we have consider as 1.5 as γ_{mf} because here Z_{py} and (Z_{ez}) Z_{ey} ratio is greater than it is 1.6 which is greater than 1.2. So if Z_{py} , Z_{ey} ratio is greater than 1.2 we know that the γ_{mf} value will be consider in place of 1.2 as 1.5, so the value is coming 4.7. So M_{dy} value is coming 5.12 and it has to be less than or equal to 4.7.

(Refer Slide Time: 22:41)

Handwritten calculations on a blue background:

$$M_{dy} = 4.7 \text{ kNm} > 0.6375 \text{ kNm}$$

$$\frac{M_z}{M_{dz}} + \frac{M_y}{M_{dy}} \leq 1$$

$$\frac{12.35}{23.75} + \frac{0.6375}{4.7} = 0.66 < 1 \quad \text{OK}$$

$$\delta_{all} = \frac{5000}{180} = 27.78 \text{ mm}$$

$$\delta = \frac{1}{384} \times \frac{wL^4}{EI} = \frac{3294.5 \times 10^{-3} \times 5000^4}{384 \times 2 \times 10^5 \times 688.2 \times 10^3}$$

$$\approx 4 \text{ mm} < 27.78 \text{ mm} \quad \text{OK}$$

Therefore the M_{dy} value can be consider as 4.7 kilonewton and it is more than the M_y value that is 0.6375 kilonewton meter, right so this is also okay, right. Now so so individual moment carrying capacity in both the directions we could find it is satisfying. Now we have to check for overall member strength means local capacity from the interaction formula that M_z by M_{dz} plus M_y by M_{dy} it has to be less than or equal to 1.

So M_z was 12.35 M_{dz} was 23.75 plus M_y was 0.6375 by 4.7 so that is becoming 0.66, right and it is less than 1 so okay. So the bending moment point of view the section is okay. So now what we need to do we need to check for deflection, right. So allowable deflection delta we know L by 180, so length was 5000 by 180 is 27.78 millimetre and delta actual is actually

1 by 384 into Wl to the power 4 by EI okay so this is coming as W is 3294.5 remember this W is the service load not the factored load 10 to the power minus 3 into l to the power 4 equal to 5000 to the power 4 by 384 into EI E is 2 into 10 to the power 5, I is 688.2. So this we are calculating 688.2 into 10 to the power 4 sorry right.

So I was so after calculating we can find out value as around 4 millimetre which is less than 27.78 millimetre so okay. Now similarly we have to check against the lateral deflection okay, so deflection in both the directions also we have to check and in other direction deflection is quite less because the load is very less so that will be also okay. So this is how one can design the purlin by checking the deflection and prior to that checking the moment, okay.

(Refer Slide Time: 26:29)

Solution:
 For steel of grade Fe 410: $f_y = 250$ MPa
 Weight of galvanized corrugated iron sheets = $120 \times 2 = 240$ N/m
 Assume dead load of purlin = 100 N/m
 Total dead load = $240 + 100 = 340$ N/m
 The dead load acts vertically downwards.
 The component of dead load parallel to roof = $340 \sin 30^\circ = 170$ N/m
 The component of dead load normal to roof = $340 \cos 30^\circ = 294.5$ N/m
 Wind pressure = $p_z = 0.6 V_z^2 = 0.6 \times 50^2 = 1500$ N/m²
 Wind load is assumed to act normal to the roof.
 Wind load = $1500 \times 2 \times 1 = 3000$ N/m
 Total load on purlin normal to roof = $3000 + 294.5 = 3294.5$ N/m
 Factored load normal to roof,
 $P = 1.5 \times 3294.5 = 4941.75$ N/m
 Factored load parallel to roof,
 $H = 1.5 \times 170 = 255$ N/m

So whatever I have discussed I am going through the PPT to review once again as we have little time. So what we did is this first that is first we have found the weight of galvanized corrugated sheet which was given 120 into spacing 2, we have assumed dead load as 100, so total dead load is becoming 340. Now component of dead load parallel to roof will be 340 into sin 30 so 170 this is parallel to the roof and normal to roof it will be 340 into cos 30 that is this 294.5.

And wind pressure will be calculated as $0.6 V_z^2$ square which is becoming 1500 newton per meter square. So the load will be into the influenced area so 3000 newton per meter and the total load on the purlin normal to roof we can calculate as 3294.5 newton per meter, right and factored load normal to roof thus we can calculate as 1.5 into this dead load plus wind load,

okay and factored load parallel to roof we can find out this. So once we find out the factored load in both the directions then we can find out the moment.

(Refer Slide Time: 28:02)

Maximum moment,
 $M_{uu} = M_z = PL/10 = (4941.75 \times 5) \times 5 \times 10^{-3} / 10 = 12.35 \text{ kNm}$
 $M_{vv} = M_y = HL/10 = (255 \times 5) \times 5 \times 10^{-3} / 10 = 0.6375 \text{ kNm}$
 Let us try a section with flange width $b_f = 75 \text{ mm}$ and depth, $d = 125 \text{ mm}$.
 Plastic section modulus required,

$$Z_{pz, reqd} = M_z \frac{\gamma_{mo}}{f_y} + 2.5 \left(\frac{d}{b} \right) \left(M_y \frac{\gamma_{mo}}{f_y} \right)$$

$$Z_{pz, reqd} = 12.35 \times 10^6 \times \frac{1.1}{250} + 2.5 \left(\frac{125}{75} \right) \left(0.6375 \times 10^6 \times \frac{1.1}{250} \right)$$

$$= 66 \times 10^3 \text{ mm}^3$$

 Select a section ISLB 150 with $Z_{pz} = 104.5 \times 10^3 \text{ mm}^3$
 $A = 1808 \text{ mm}^2$, $D = 150 \text{ mm}$, $b_f = 80 \text{ mm}$, $t_f = 6.8 \text{ mm}$, $t_w = 4.8 \text{ mm}$
 $R_1 = 9.5 \text{ mm}$,
 $d = 150 - 2(6.8 + 9.5) = 117.4 \text{ mm}$

So moment will become M_{uu} as W_l by 10 that is this 12.35 kilonewton meter, similarly M_{vv} will become 0.6375 kilonewton and now we need to know a approximate plastic section modulus to start with an approximate section so Z_{pz} required we can calculate from this formula which was proposed by the Gaylord Et Al. And according to that we need the Z_{pz} as 66 remember for finding out Z_{pz} required we need to put some assumed value of d by b , so d and b we have assumed as this to calculate the Z_{pz} required.

So once we calculate the Z_{pz} required as 66.10 cube we can select a section and for this we have selected a section of ISLB 150 for which the Z_{pz} value is 104.5 into 10 cube and for this ISLB section the relevant properties are consider from SP 6 like the cross-sectional area, the depth, the width of flange, thickness of flange, width of the web, root radius R_1 and we can calculate the effective depth as this 117.4.

(Refer Slide Time: 29:40)

$$I_z = 688.2 \times 10^4 \text{ mm}^4, I_y = 55.2 \times 10^4 \text{ mm}^4$$

$$Z_{ez} = 91.8 \times 10^3 \text{ mm}^3, Z_{ey} = 13.8 \times 10^3 \text{ mm}^3$$

Section classification

$$\epsilon = \sqrt{\frac{250}{f_y}} = \sqrt{\frac{250}{250}} = 1$$

$$b/t_f = 40/6.8 = 5.88 < 9.4$$

$$d/t_w = 117.4/4.8 = 24.5 < 84$$

Hence the section is plastic.

Check for bending strength

$$M_{dz} = Z_{pz} \frac{f_y}{\gamma_{m0}} = 104.5 \times 10^3 \times \frac{250}{1.1} \times 10^{-6} = 23.75 \text{ kN-m}$$

$$< 1.2 Z_{ez} \frac{f_y}{\gamma_{m0}} = 1.2 \times 91.8 \times 10^3 \times \frac{250}{1.1} \times 10^{-6} = 25.04 \text{ kN-m}$$

Which is alright. ✓

Also we can note down the properties of I_z as this, I_y as this, Z_{ez} and Z_{ey} and then we can find out the type of section through section classification and we could see that the section is plastic. Then we can find out the M_{dz} value the design bending strength which is coming 23.75 kilonewton meter and which should be less than the value that is 1.2 Z_{ez} into f_y by γ_{m0} . So as this is less so we can say this is okay and the design bending strength is more than the bending moment coming on that direction. So the member section whatever we have chosen is okay.

(Refer Slide Time: 30:40)

$$M_{dy} = Z_{py} \times \frac{f_y}{\gamma_{m0}} \leq \gamma_f Z_{ey} \frac{f_y}{\gamma_{m0}}$$

$$Z_{py} = 4 \times \left[\left(\frac{b_f}{2} \times t_f \right) \times \frac{b_f}{4} \right] + 2 \times \left[\left\{ (D - 2t_f) \times \frac{t_w}{2} \right\} \times \frac{t_w}{4} \right]$$

$$Z_{py} = \frac{t_f b_f^2}{2} + \frac{(D - 2t_f) t_w^2}{4} = \frac{6.8 \times 80^2}{2} + \frac{(150 - 2 \times 6.8) 4.8^2}{4}$$

$$= 22546 \text{ mm}^3$$

$$M_{dy} = 22546 \times 250/1.1 \times 10^{-6} = 5.12 \text{ kN-m}$$

$$< 1.5 \times 13.8 \times 10^3 \times 250/1.1 \times 10^{-6} = 4.7 \text{ kN-m}$$

(1.2 is replaced by $\gamma_f = 1.5$ since $Z_{py}/Z_{ey} (=1.6) > 1.2$)

Hence, $M_{dy} = 4.7 \text{ kN-m} > 0.6375 \text{ kN-m}$; OK

Similarly in other directions also we have calculated the design bending strength M_{dy} , so to calculate M_{dy} we need to find out Z_{py} which is not given in the SP 6 or IS 800, so we need

to calculate manually so Z_{py} we have calculated from this formula how we have derived we have shown while working out. So from that Z_{py} value was this, so then M_{dy} value we can find out as this, okay. So M_{dy} value is should be less than the value that is 1.2 into $Z_{e fy}$ by γ_{m0} , here 1.2 will be replaced by the γ_f as Z_{py} by Z_{ey} value is more than 1.2.

So with those the M_{dy} value is coming 4.7 and as it is less than 5.12 so we should consider M_{dy} value as 4.7 kilonewton meter and it is more than 0.6375 so okay, right. So individually the bending strength in both the directions are fine for the assumed section.

(Refer Slide Time: 32:09)

Check for overall member strength (local capacity)

$$\frac{M_z}{M_{dz}} + \frac{M_y}{M_{dy}} \leq 1$$

$$\frac{12.35}{23.75} + \frac{0.6375}{4.7} = 0.66 < 1; \text{OK}$$

Check for deflection

$$\delta_{all} = 5000/180 = 27.78 \text{ mm}$$

$$\Delta = \frac{5}{384} \times \frac{w l^4}{EI}$$

$$= \frac{5 \times 3294.5 \times 10^{-3} \times 5000^4}{384 \times 2 \times 10^5 \times 688.2 \times 10^4}$$

$$= 19.5 \text{ mm} > \delta_{all}; \text{OK.}$$

Now we will go for the combined one that through the interaction formula we can see that M_z by M_{dz} plus M_y by M_{dy} is less than 1 because the value is coming 0.66 which is less than 1 so it is okay. Now we will go for deflection check for deflection check allowable deflection is 27.78, now the actual deflection will be 1 by 384 into $w l$ to the power 4 by EI , here we should consider 1 because it is a continuous, right.

So if we consider 1 then the value will be around 4 millimetre and which is which is less than allowable allowable deflection so it is okay, right. So this is how we can find out the section, right. So in today's lecture we could see that how to find out the section of a purlin member while using I section and how to calculate the biaxial bending moment formula means how to check the biaxial bending moment that also we have seen. And first we have seen how to find out the approximate section from the Gaylord formula that also we have noticed. So using this we can design a purlin, right. Next we will discuss about the Gantry Girders because

Gantry Girder is nothing but one type of flexural member. So how to design that Gantry Girder that will be discussed in next class, thank you.
