Lecture # 61
Introduction to wave mechanics (Contd.)

(Refer Slide Time: 00:32)

Welcome back students for this third lecture of this module, where we are deriving the velocity potential of the ocean surface waves. Last time we concluded with this particular slide indicating the definition sketch of the wave motion, where we have told you what the water depth is this figure is actually very important for understanding how this linear wave is represented. The wavelength is given as L at the top the depth is indicated wave height H is also given no sea bed is shown so we from this point onward will continue with our derivation.

(Refer Slide Time: 01:00)

SOLUTION TO THE LAPLACE EQUATION:

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial z^2} = 0 \quad (2.6)$$

- Method of separable is used to obtain the solution to Eqn. (2.6)
- Let us assume

$$\phi(x, z, t) = \bar{X}(x)\bar{Z}(z)\bar{T}(t) \quad (2.7)$$

Now we have listed the boundary conditions one was $w = 0$ at the bottom second was we specified free surface dynamic free surface boundary condition at the top. And now we start with the solution of the Laplace equation. So, Laplace equation in terms of velocity potential in 2 dimension, as we have assumed x and z is $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 0$.

To obtain the solution a very simple method of separable is used to obtain the solution to this equation which is 2.6. Our let us assume, main method of separable ϕ of x, z, t can be written as \bar{X} as a function of x it can be separated \bar{Z} as z , \bar{T} as t .

(Refer Slide Time: 01:55)

- Substituting Eq. (2.7) in Eq. (2.6) we get

$$\bar{X}'' \bar{Z} \bar{T} + \bar{X} \bar{Z}'' \bar{T} = 0$$

- Where each prime denotes differentiation once with respect to the particular independent variable.
- Dividing both side of the above $\bar{X} \bar{Z} \bar{T}$ gives

$$\frac{\bar{X}''}{\bar{X}} = -\frac{\bar{Z}''}{\bar{Z}}$$

Now, if we substitute 2.7 this equation into 2.6 because due to the velocity potential Laplace equation properties, we are able to separate X , Z and T using the method of separable what do we get x double bar. So, x double prime bar Z bar and T bar + X bar Z double prime whole bar and T bar = 0. Here each prime denotes differentiation once with respect to the particular independent variable for double means double differential. Now, if we divide both sides by X bar, Z bar and T bar, we get X bar X double prime bar by X bar = - Z double prime whole bar by said this is the equation that we get.

(Refer Slide Time: 03:03)

• Let this be constant = $-k^2$; then

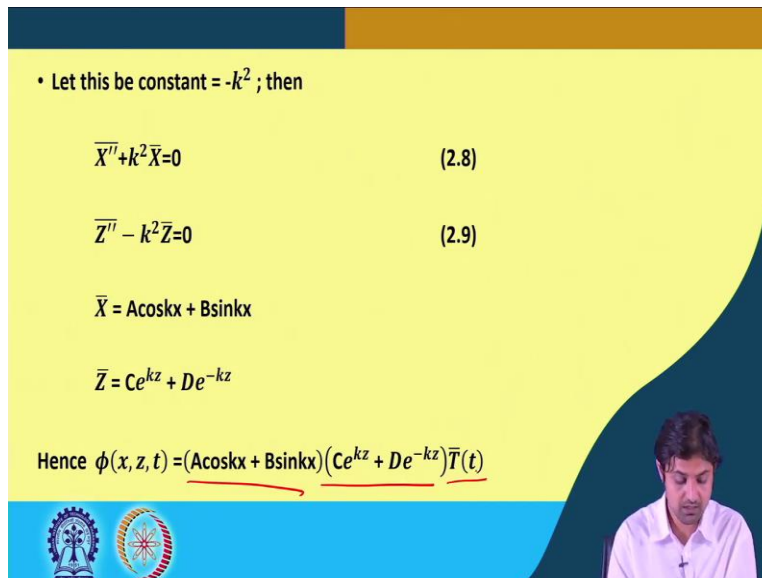

$$\bar{X}'' + k^2 \bar{X} = 0 \quad (2.8)$$

$$\bar{Z}'' - k^2 \bar{Z} = 0 \quad (2.9)$$

$$\bar{X} = A \cos kx + B \sin kx$$

$$\bar{Z} = C e^{kz} + D e^{-kz}$$

Hence $\phi(x, z, t) = (A \cos kx + B \sin kx) (C e^{kz} + D e^{-kz}) \bar{T}(t)$

Now, see this is we let us say this is a constant - K square, then we can write 1 of the equations from this will come X double prime bar + k squared x bar = 0 and the second one will be Z double prime bar - k square z bar = 0, these 2 are very famous equation the solution for this is standard. So, x bar from 2.8 can be written as $A \cos kx + B \sin kx$. Whereas Z from equation number 2.9 solution to this type of equation is here solution to the equations of type 2.9 is this one from equation 2.9.

We get X bar and Z bar so, we can simply write so, you see we had the solution that we all initially assumed was $\phi(x, z, t)$ is X bar, Z bar and T bar so we can write instead of X bar we can write this one instead of Z bar we can read this one and T bar remains as T bar.

(Refer Slide Time: 04:38)

- Let this be constant $= -k^2$; then

$$\bar{X}'' + k^2 \bar{X} = 0 \quad (2.8)$$

$$\bar{Z}'' - k^2 \bar{Z} = 0 \quad (2.9)$$

$$\bar{X} = A \cos kx + B \sin kx$$

$$\bar{Z} = C e^{kz} + D e^{-kz}$$

$$\text{Hence } \phi(x, z, t) = (A \cos kx + B \sin kx) (C e^{kz} + D e^{-kz}) \bar{T}(t)$$

Now, the solutions to ϕ are simple harmonic in time, that is, because we know from previous that they are waves and periodic in time. Therefore, \bar{T} can be simply replaced as $\cos t$ or $\sin t$ anything it can be replaced, and therefore with each of the values of $\sin t$ or $\cos t$, we have 4 forms of ϕ one will be $A \cos kx$ multiplied by \sin , the other would be $A \cos kx$ multiplied by \cos . The other would be $B \sin kx$ multiplied by \sin and then the third the fourth one would be $B \sin kx$ multiplied by \cos .

(Refer Slide Time: 05:32)

- The solutions to ϕ are simple harmonic in time requiring $\bar{T}(t)$ be replaced as $\cos(\sigma t)$ or $\sin(\sigma t)$, thus leading to four forms of solutions to ϕ , such that

$$\bullet \phi_1 = A_1 (C e^{kz} + D e^{-kz}) \cos(kx) \cdot \cos(\sigma t)$$

$$\bullet \phi_2 = A_2 (C e^{kz} + D e^{-kz}) \sin(kx) \cdot \sin(\sigma t)$$

$$\bullet \phi_3 = A_3 (C e^{kz} + D e^{-kz}) \sin(kx) \cdot \cos(\sigma t)$$

$$\bullet \phi_4 = A_4 (C e^{kz} + D e^{-kz}) \cos(kx) \cdot \sin(\sigma t)$$

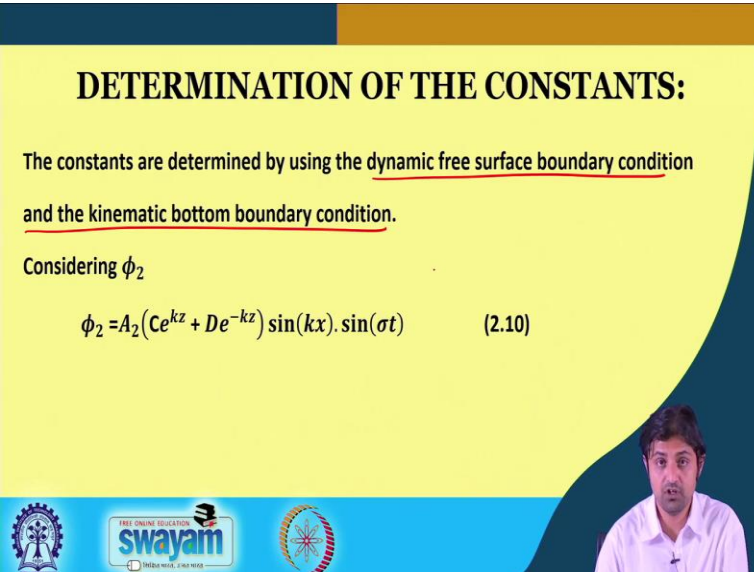

So we can write 4 different terms A_1 we did not touch this, so $A \cos kx + B \sin kx$ multiplied by either $\sin \sigma t$ or $\cos \sigma t$. There are going to be 2 terms when we assume t as a function of $\sin \sigma t$, and they would not mean after multiplication with this and there will be 2

other term is if instead of sin we assume cos t bar T . So total we can write 4 terms, ϕ_1 will be A_1 into $C e$ to the power $k z$ cos $k x$ cos σt . Another thing would be $A_2 C e$ to the power $k z$ + $D e$ to the power $- k x$ sin $k x$ sin σt .

The third would be sine $k x$ cos σt and fourth would be cos $k x$ sin σt . However the total velocity potential is going to be some of 2 of those which one we will come to it later. But for now, we have assumed 4 different terms $\phi_1 \phi_2 \phi_3 \phi_4$, 1 would be $\phi_1 - \phi_2$ the other could be $\phi_3 - \phi_4$, but that will come to later.

(Refer Slide Time: 07:01)

DETERMINATION OF THE CONSTANTS:

The constants are determined by using the dynamic free surface boundary condition and the kinematic bottom boundary condition.

Considering ϕ_2

$$\phi_2 = A_2 (C e^{kz} + D e^{-kz}) \sin(kx) \cdot \sin(\sigma t) \quad (2.10)$$

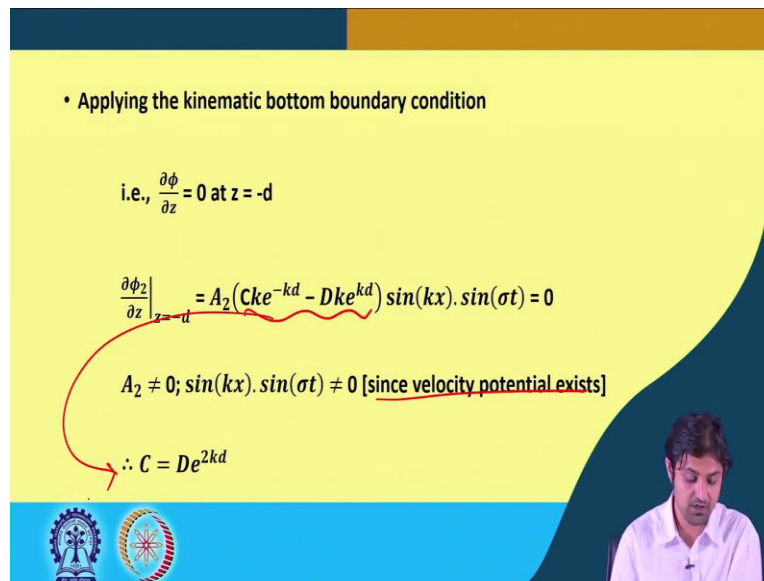

The slide also features logos for Swayam and other educational institutions at the bottom.

So, we have to see this these terms $\phi_1, \phi_2, \phi_3, \phi_4$ are constants A_1, C, D, σ is related to the time period case rate to the wave period that will come to it later. But more importantly we have to find these constants A_1, C and D . So, how did it remind these constants, the constants are determined using the dynamic free surface boundary condition and the kinematic bottom boundary condition as you would remember, because, by the definition of the boundary condition, we said that, there could be infinite number of solutions to a governing equation?

However, with the application of boundary condition, we can find one or more unique solutions to the problem that is what we are going to do. These constant will be determined from the boundary Conditions let us consider ϕ_2 is one velocity potential that we have written here this

one. So, what does it say ϕ_2 is A_2 into $C e$ to the power $kz + D e$ to the power $-kz$ into $\sin kx$ into $\sin \sigma t$ we call this equation number 2.10.

(Refer Slide Time: 08:29)

• Applying the kinematic bottom boundary condition

i.e., $\frac{\partial \phi}{\partial z} = 0$ at $z = -d$

$$\left. \frac{\partial \phi_2}{\partial z} \right|_{z=-d} = A_2 (Cke^{-kd} - Dke^{kd}) \sin(kx) \cdot \sin(\sigma t) = 0$$

$A_2 \neq 0; \sin(kx) \cdot \sin(\sigma t) \neq 0$ [since velocity potential exists]

$\therefore C = De^{2kd}$

If we apply the kinematic bottom boundary condition, which means fields the velocity potential ϕ is given by $\frac{\partial \phi}{\partial z}$ and that will be 0 at $z = -d$. If you apply that $\frac{\partial \phi}{\partial z}$ at $z = -d$ it will be A_2 into $C e$ to the power $-kd - D k e$ to the power kd into $\sin kx \sin \sigma t = 0$ at $z = -d$. So, now there is no Z but instead of Z we have d . So, A_2 is not equal to 0 otherwise there is not going to be any wave also $\sin kx \sin \sigma t$ will not be 0 because there will be a velocity potential if we substitute them to be either one of them to be 0 the velocity potential becomes 0.

So that means these 3 terms cannot be 0. Therefore, the only thing is that this be 0 and if we utilize this we are going to get C as D into e to the power kd . So with one boundary condition we have reduced our unknown by 1 number. $C = D e^{2kd}$ we have related C and D .

(Refer Slide Time: 09:48)

Substituting for C in (Eq. 2.10) and simplifying,

$$\phi_2 = 2A_2 D e^{kd} \left(\frac{e^{k(d+z)} + e^{-k(d+z)}}{2} \right) \sin(kx) \sin(\sigma t)$$

$$\phi_2 = 2A_2 D e^{kd} \cosh k(d+z) \sin(kx) \sin(\sigma t) \quad (2.11)$$

Now if we substitute for C in equation 2.10 so instead of CV put 2d into what the term that we have got we are going to get $\phi_2 = 2A_2 D e^{kd} \sin kx \sin \sigma t$ or simply we can write this is nothing but $\cosh kd + z$. Simple trigonometry.

(Refer Slide Time: 10:37)

$$\left. \frac{\partial \phi_2}{\partial t} \right|_{z=0} = 2A_2 D \sigma e^{kd} \cdot \cosh kd \cdot \sin(kx) \cdot \cos(\sigma t)$$

On assuming

$$\eta = a \sin(kx) \cos(\sigma t) \text{ where } a = \text{wave amplitude} = \frac{H}{2} \text{ and applying the free}$$

surface boundary condition $\left\{ \eta = \frac{1}{g} \frac{\partial \phi_2}{\partial t} \right\}_{z=0}$ we get

$$\frac{1}{g} \frac{\partial \phi_2}{\partial t} \Big|_{z=0} = \eta$$

So, we have got ϕ_2 is $2A_2 D e^{kd} \cosh k(d+z)$ so we are left with A_2 and D for now. And if we do $\frac{\partial \phi_2}{\partial t}$ at $Z = 0$. We get $2A_2 D \sigma e^{kd} \cosh kd \sin kx \cos \sigma t$ and on assuming if we assume that free surface elevation is $A \sin kx \cos \sigma t$. So, what we are going to do here is the wave amplitude that is $H/2$ this is our assumption and by applying the free surface boundary condition that $\eta = \frac{1}{g} \frac{\partial \phi_2}{\partial t}$ at $Z = 0$.

So, first we are applied the bottom boundary condition. On the second step we want to apply the dynamic free surface boundary condition. So, for applying the dynamic free surface boundary condition we need to calculate this term one by $g \frac{\partial \phi}{\partial z}$ at $Z = 0$. And this is what we get this term and this we equate to η is the free surface which $= A \sin kx \sin \sigma t$.

(Refer Slide Time: 12:13)

$$a \sin(kx) \cdot \cos(\sigma t) = \frac{2A_2 D \sigma e^{kd}}{g} \cdot \cosh kd \cdot \sin(kx) \cdot \cos(\sigma t)$$

$$2A_2 D e^{kd} = \frac{ag}{\sigma \cosh kd}$$

$\sigma = \frac{2\pi}{T} \rightarrow \text{time period}$
 $k = \frac{2\pi}{L} \rightarrow \text{wavelength}$

Substituting in eq. (2.11), we get

$$\phi_2 = \frac{ag}{\sigma} \frac{\cosh k(d+z)}{\cosh kd} \sin(kx) \cdot \sin(\sigma t) \quad (2.12)$$

So simply what we do $\eta =$ and after solving for this we get $2A_2 D e^{kd}$ is ag by σ into 1 by $\cosh kd$. And if we substitute these values into our original ϕ_2 we are going to get it as $\phi_2 = \frac{ag}{\sigma} \cosh k(d+z) \cosh kd \sin kx \sin \sigma t$. So, we have now, first what we did we solve for Laplace equation applied the 2 boundary conditions and obtain the value of the velocity potential ϕ_2 which is of the form $\frac{ag}{\sigma} \cosh k(d+z) \cosh kd \sin kx \sin \sigma t$.

So, σ is 2π by T and k is 2π by L this is wavelength and this is time period for you the derivation is not important what the results are, but the derivation is important in a way that it makes you appreciate how starting from the basics we can derive these equations they will ask the potential.

(Refer Slide Time: 14:16)

• $a \sin(kx) \cdot \cos(\sigma t) = \frac{2A_2 D \sigma e^{kd}}{g} \cdot \cosh kd \cdot \sin(kx) \cdot \cos(\sigma t)$

$$2A_2 D e^{kd} = \frac{ag}{\sigma \cosh kd}$$

Substituting in eq. (2.11), we get

$$\phi_2 = \frac{ag \cosh k(d+z)}{\sigma \cosh kd} \sin(kx) \cdot \sin(\sigma t) \quad (2.12)$$

Let us consider ϕ_3

I do not expect you to remember the derivation but the steps you must know the things like the specifying the governing equation, what are the governing equations governing equation is Laplace equation for the boundary conditions we utilize the Bernoulli's equation and the continuity equation for example, so, we have obtained phi 2 here.

(Refer Slide Time: 14:42)

$$\phi_3 = A_3 (C e^{kz} + D e^{-kz}) \sin(kx) \cdot \cos(\sigma t) \quad (2.13)$$

• Applying the kinematic bottom boundary condition

$$\left. \frac{\partial \phi_3}{\partial z} \right|_{z=-d} = A_3 (C k e^{-kd} - D k e^{kd}) \sin(kx) \cdot \cos(\sigma t) = 0$$

• $A_3 \neq 0; \sin(kx) \cdot \cos(\sigma t) \neq 0$

$$C = D e^{2kd}$$

• Substituting for C in eq. (2.13)

So, if we consider phi 3 and apply the same concepts that phi 3 = you know, we apply the dynamic boundary condition. This will give C equal to D into e to the power 2 k d.

(Refer Slide Time: 14:59)

Substituting in eq. (2.14), we get

$$\phi_3 = \frac{-ag \cosh k(d+z)}{\sigma \cosh kd} \sin(kx) \cdot \cos(\sigma t) \quad (2.15)$$

Let us consider ϕ_4

$$\phi_4 = A_4 (C e^{kz} + D e^{-kz}) \cos(kx) \cdot \sin(\sigma t) \quad (2.16)$$

Applying the kinematic bottom boundary condition

$$\left. \frac{\partial \phi_4}{\partial z} \right|_{z=-d} = A_4 (C k e^{-kd} - D k e^{kd}) \cos(kx) \cdot \sin(\sigma t) \longrightarrow C = D e^{2kd}$$

Substituting for C in eq. (2.16)

And same procedure is repeated for the dynamic free surface boundary condition and we get for phi 3 at term like this, you understand same procedure. So phi 3 we get $-ag$ by $\sigma \cosh kd + z$ similarly, we get phi 3. And same procedure we do for phi 4, for obtaining the values.

(Refer Slide Time: 15:30)

$$\phi_4 = 2A_4 D e^{kd} \cosh k(d+z) \cos(kx) \cdot \sin(\sigma t) \quad (2.17)$$

And

$$\left. \frac{\partial \phi_4}{\partial t} \right|_{z=0} = 2A_4 D e^{kd} \cosh k(d+z) \cos(kx) \cdot \sin(\sigma t)$$

Assuming $\eta = a \cos(kx) \cdot \cos(\sigma t)$ and applying eq (2.5)

We get $2A_4 D e^{kd} = \frac{ag}{\sigma \cosh kd}$

(Refer Slide Time: 15:31)

- Substituting in eq. (2.17), we get

$$\phi_4 = \frac{ag}{\sigma} \frac{\cosh k(d+z)}{\cosh kd} \cos(kx) \sin(\sigma t) \quad (2.18)$$

- Let us consider ϕ_1

$$\phi_1 = A_1 (C e^{kz} + D e^{-kz}) \cos(kx) \cos(\sigma t) \quad (2.19)$$

- Applying the kinematic bottom boundary condition

$$\left. \frac{\partial \phi_1}{\partial z} \right|_{z=-d} = 0 \quad C = D e^{2kd}$$

And what we get ϕ_4 is $\frac{ag}{\sigma}$ by a similar result we get and we repeat the same procedure again for ϕ_1 .

(Refer Slide Time: 15:46)

- Substituting for C in eq. (2.19)

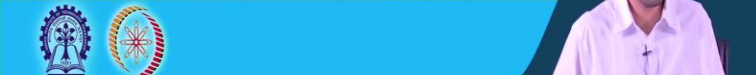

$$\phi_1 = 2A_1 D e^{kd} \cosh k(d+z) \cos(kx) \cos(\sigma t) \quad (2.20)$$

- assuming $\eta = a \cos(kx) \sin(\sigma t)$ and applying equation (2.5)

We get

$$2A_1 D e^{kd} = \frac{-ag}{\sigma} \frac{1}{\cosh kd}$$

- Substituting in eq. (2.20), we get

$$\phi_1 = \frac{-ag}{\sigma} \frac{\cosh k(d+z)}{\cosh kd} \cos(kx) \cos(\sigma t) \quad (2.21)$$

Applying the kinematic bottom boundary condition first and then applying the dynamic. See I am skipping because it is essentially the same process.

(Refer Slide Time: 15:53)

- If $\phi^+ = \phi_2 - \phi_1$

$$= \frac{ag \cosh k(d+z)}{\sigma \cosh kd} [\cos(kx) \cdot \cos(\sigma t) + \sin(kx) \cdot \sin(\sigma t)]$$

$$\phi = \frac{ag \cosh k(d+z)}{\sigma \cosh kd} \cdot \cos(kx - \sigma t). \quad (2.22)$$

- This is the expression for the velocity potential for a propagating wave in a constant water depth

More important is this term so ϕ_1 we get is $-ag$ by $\sigma \cosh k(d+z)$ if you remember, ϕ_2 and ϕ_4 was positive with a positive sign ϕ_4 and ϕ_1 was with the negative sign after the derivation. Now you remember I said that the total velocity potential will be the summation of the two terms. So our velocity potential is going to be $\phi_2 - \phi_1$, or also in terms of ϕ_3 and ϕ_4 also so this becomes, so if you add to velocity potential, this was you know, ϕ_2 .

And, this one with a negative sign was ϕ_1 so, we get this so, $\cos kx \cos \sigma t + \sin kx \sin \sigma t$ can be return as $\cos kx - \sigma t$ using trigonometry. So, the final velocity potential with the value I mean the formula for which you are supposed to remember is this ag by $\sigma \cosh k$ into $d+z$ divided by $\cosh kd$ into $\cos kx - \sigma t$ this is the final velocity potential. So, now if you see we have determined ϕ is the amplitude of the wave.

σ is 2π by t k is 2π by L everything you know. So, as a function of x we have found out the velocity potential here as I said this is the expression for the velocity potential for a propagating wave in a constant water depth. So, this is at one particular constant water depth, this is the velocity potential which we have derived from hydraulic assumptions and conditions.

(Refer Slide Time: 18:36)

Since $\eta = \frac{1}{g} \frac{\partial \phi}{\partial t} \Big|_{z=0}$

$$\eta = \frac{1}{g} \frac{ag}{\sigma} \frac{\cosh k(d+z)}{\cosh kd} \cdot \sigma \sin(kx - \sigma t).$$

Hence $\eta = a \sin(kx - \sigma t)$. phase (2.23)

- ' η ' is periodic in x and t . If we locate a point and traverse along the wave, such that, at all-time ' t ' our position relative to the wave form remains fixed then the phase difference is zero or $kx - \sigma t = \text{constant}$

Now, because we have got the velocity potential we can finally write the term for eta, we are going to check so, eta can be return as so, $\frac{1}{g} \frac{\partial \phi}{\partial t}$ at $z = 0$ will come out to be this one. So, ag can be return as so, if you just g and g will cancel σ and σ will cancel. So, at $z = 0$, this will also get canceled. So, simply we left with $\eta = a \sin(kx - \sigma t)$.

So, now this eta is periodic in x and t , if we locate a point and traverse along the wave says that at all time t , our position relative to the waveform remains fixed. So, basically this term $kx - \sigma t$ from your earlier mechanics class you would know this is what this is the phase $kx - \sigma t$. So, with this phase we do an experiment what we do is if we locate a point and traverse along the waves such that at any time t our position relative to the waveform remains fixed.

Then this means that $kx - \sigma t$ will be 0 phase difference is going to be 0 which means that $kx - \sigma t$ is going to be constant. Because if phase will be constant phase difference is going to be 0.

(Refer Slide Time: 20:39)

• And the speed with which we must move to accomplish this is given by $kx = \sigma t + \text{constant}$

$$k \frac{dx}{dt} = \sigma$$

$$\frac{dx}{dt} = \frac{\sigma}{k} = \frac{2\pi}{T} \frac{L}{2\pi} = \frac{L}{T} = C$$

• $C = \frac{L}{T} = \text{CELERITY or Speed of the wave}$ (2.24)

And the speed with which we must move to accomplish this will be given by $kx = \sigma t + \text{constant}$ or $kx = \sigma t + \text{constant}$. On differentiating we can get this equation we differentiate we get $k \frac{dx}{dt} = \sigma$ we differentiate with respect to time = σ or $\frac{dx}{dt}$ can be written as σ by k , and σ was nothing but $\frac{2\pi}{T}$ and k was nothing but $\frac{2\pi}{L}$. So, it becomes $\frac{L}{T}$ and that is the C and C is the wave celerity.

So, to determine the velocity of the wave, this is the so, this is how the wave celerity that is length wave length by time period is the celerity and this is the basis of finding the way of celerity that if locate a point and traverse along the wave such that at all time t our position relative to the waveform remains fixed when this will happen when we are going to move with the speed of the wave. And that our speed and wave speed will be the same in that case and that is what we have found out that $C = \frac{L}{T}$ is the celerity of the wave with which we must be moving.

(Refer Slide Time: 22:14)

Wave moving in negative 'x' direction

- If $\phi^- = \phi_2 + \phi_1$

$$= \frac{-ag \cosh k(kx + \sigma t)}{\sigma \cosh kd} \cdot \cos(kx + \sigma t).$$
- Since $\eta = \frac{1}{g} \frac{\partial \phi}{\partial t} \Big|_{z=0}$

$$\eta = \frac{1}{g} \frac{-ag \cosh k(d+z)}{\sigma \cosh kd} (-\sigma \sin(kx + \sigma t))$$

$$\eta = a \sin(kx + \sigma t)$$

Now, if there is a wave that is moving in x direction, then we can simply write the velocity potential $\phi^- = \phi_2 + \phi_1$ not $-\phi_1$ and then we will get nothing but with $-\sin$ - ag by $\sigma \cosh kx \sigma kx + \sigma t$ into $\cosh kd$. So, what you do is you do $x =$ so, instead of $kx + -\sigma t$ becomes $\cos kx + \sigma t$. So, this is a different waveform. So, in this case, since a is

1 by g we will also get a similar you know, if there was it will remember it was $kx - \sigma t$ it becomes $kx + \sigma t$. So, the phase is changing when the wave is traveling in the negative direction.

(Refer Slide Time: 23:15)

To obtain the celerity of the wave we have

$$kx + \sigma t = \text{constant}$$

$$\frac{dx}{dt} = \frac{-\sigma}{k} = \frac{-2\pi}{T} \frac{L}{2\pi} = \frac{-L}{T} = -C \quad (2.25)$$

Now, to obtain the celerity of the wave in this case we have $kx + \sigma t = \text{constant}$ same procedure is repeated. So, it will become - c sonic wave negative means negative celerity in the negative x direction.

(Refer Slide Time: 23:34)

DISPERSION RELATIONSHIP

- The relationship between wavelength, period and water depth is obtained as given below. The main assumption while establishing the relationship is that, since, we are dealing with small amplitude waves, meaning that the slope of the wave profile are small so that $\frac{d\eta}{dt}$ can be approximately said as equal to the vertical component velocity, w . This is

$$w = \frac{d\eta}{dt} = \frac{\partial \eta}{\partial t} + \frac{\partial \eta}{\partial x} \frac{\partial x}{\partial t}$$

Handwritten notes on the slide include a red arrow pointing to the $\frac{\partial \eta}{\partial x} \frac{\partial x}{\partial t}$ term with a '0' next to it, and another red arrow pointing to the $\frac{d\eta}{dt}$ term with a $\frac{d\eta}{dt}$ next to it.

- Wave slope being small by setting, $\frac{\partial \eta}{\partial x} = 0$

The slide also features two logos at the bottom left and a video inset of a lecturer at the bottom right.

Now, one important thing after this derivation of the velocity potential is something called a dispersion relationship that is one of the core concept of the wave mechanics. So, the relationship between wavelength with period and water depth is obtained as given below for the dispersion relationship, the main assumption while establishing the relationship is that since we are dealing with small amplitude waves, meaning that the slope of wave profile are so, small that $\frac{d\eta}{dt}$ can be approximately said equal to the vertical component of the velocity w .

So, w can be written as $\frac{d\eta}{dt}$ or in differential form $\frac{d\eta}{dt} = \frac{\partial \eta}{\partial t} + w$ is what $\frac{d\eta}{dt}$ because that is the vertical velocity correct $\frac{d\eta}{dt}$. So, that if you apply the total you know, differentiation by you know, total differentiation, it will be $\frac{d\eta}{dt} = \frac{\partial \eta}{\partial t} + \frac{\partial \eta}{\partial x} \frac{dx}{dt}$. So, wave slope being small means $\frac{\partial \eta}{\partial x} = 0$ which implies $\frac{d\eta}{dt} = \frac{\partial \eta}{\partial t}$.

(Refer Slide Time: 25:19)

$w = \frac{\partial \eta}{\partial t}$ but $w = -\frac{\partial \phi}{\partial z}$
 Hence $\frac{\partial \eta}{\partial t} = -\frac{\partial \phi}{\partial z}$ (2.26)

Differentiating the expression of η we get $\frac{\partial \eta}{\partial t} = \frac{1}{g} \frac{\partial^2 \phi}{\partial t^2} \Big|_{z=0}$

Hence $\frac{\partial \eta}{\partial t} = \frac{-A\sigma^2}{g} \cosh kd \cdot \cos(kx - \sigma t)$. (2.27)

$W = \text{del } \eta \text{ del } t$ but w also equal to $-\text{del } \phi \text{ del } z$ in form of velocity potential hence $\text{del } \eta \text{ by del } t$ equal to $-\text{del } \phi \text{ del } z$ we know the velocity potential we know the equation of a η , if we do the differentiation of a η we get $\text{del } t = 1$. So, if you do the differentiating the expression of η , what do we get? $\text{Del } \eta \text{ by del } t = 1$ by g you remember, that term headset $= 0$ 1 by $g \text{ del square } \phi \text{ by del } t \text{ square}$.

η was $\frac{1}{g} \text{ del } \phi \text{ del } t$ at $z = 0$. So, if you differentiate this you get $\text{del } \eta \text{ del } t = \frac{1}{g} \text{ del } t \text{ square } \phi \text{ by del } t \text{ square}$ that $= 0$ this is what it is written here so, we substitute $\text{del } \eta \text{ by del } t$ we get from here.

previous page
 • Where $A = \frac{H g}{2 \sigma \cosh kd}$

$w = \frac{-\partial \phi}{\partial z} = -Ak \sinh kd \cdot \cos(kx - \sigma t)$. (2.28)

• Using the relation of Eq. (2.26), equating Eq. (2.27) to Eq (2.28), we get

$\frac{A\sigma^2}{g} \cosh kd \cdot \cos(kx - \sigma t) = Ak \sinh kd \cdot \cos(kx - \sigma t)$.

Where σ = be write capital A is where A is here is H by 2 into g by σ divided one by $\cosh kd$ and w is also $-\frac{\partial \pi}{\partial z}$ it that is $-Ak \sinh kd$ into $\cos kx$ into σt . And we equate this both these term $A \sigma^2$ from the previous equation with this one here from the previous page because both are same.

(Refer Slide Time: 27:30)

- $\frac{\sigma^2}{g} = \frac{k \sinh kd}{\cosh kd}$ *tanh kd*
- $\sigma^2 = gk \tanh kd$ (2.29) *Dispersion relationship*
- σ : Wave angular frequency = $\frac{2\pi}{T}$ and k : wave number = $\frac{2\pi}{L}$
- The above equation can be written as
- $\left(\frac{2\pi}{T}\right)^2 = g \left(\frac{2\pi}{L}\right) \tanh kd$

And on canceling the common terms what we get is $\sigma^2 = gk \sinh kd$ divided by $\cosh kd$ and this is nothing but $\tanh kd$. So, σ^2 can be written as $gk \tanh kd$. Here σ is the wave angular frequency equal to 2π by T and k = wave number which = 2π by L as we have seen before and this above equation can be written as 2π by T whole square = g into 2π by L into $\tanh kd$. So, actually this is the famous dispersion relationship.

(Refer Slide Time: 28:29)

$$\left(\frac{L}{T}\right)^2 = \frac{gL}{2\pi} \tanh kd$$

$$(C)^2 = \frac{g}{k} \tanh kd \quad (2.30)$$

The speed at which a wave moves in its direction of propagation as a function of water depth is given by Eq.(2.30)

Since

$C = \frac{L}{T}$ from the above equation we get

So, but is substituting since sigma and k in terms we get L by T whole square = gL by 2 pi into tan h k d or C squared =, because it can be written as C square = g by k into tan h k d. So, the speed at which a wave moves in the direction of propagation as a function of what a depth can be given by equation. Earlier we obtained the velocity potential at constant depth but now we have found out the speed of the wave as a function of water depth.

(Refer Slide Time: 29:05)

$$C = \sqrt{\frac{gL}{2\pi} \tanh kd} \quad (2.31)$$

$$\text{Or } L = \frac{gT^2}{2\pi} \tanh kd \quad (2.32)$$

• Since the unknown 'L' occurs on both sides (Implicit Eq.) of Eq. (2.32), it has to be solved by trial and error.

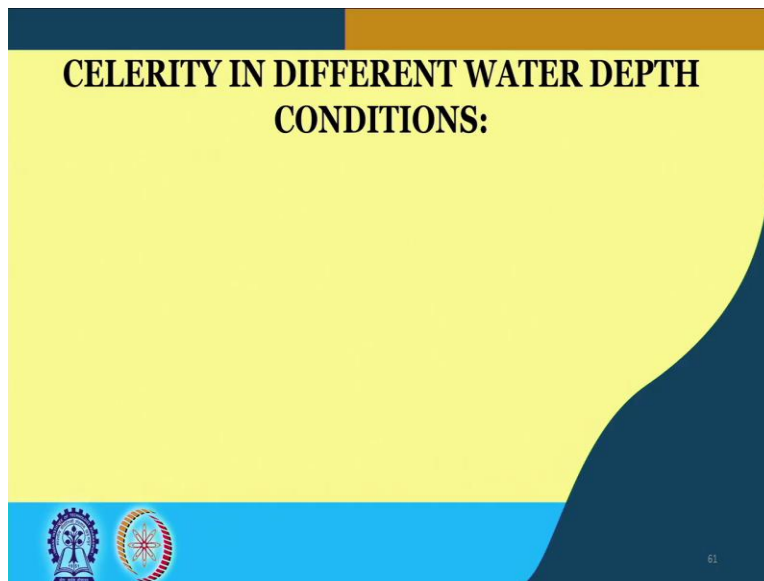

Since $C = L$ by T , we get $C =$ we just writing it in a different form. So C can be written as gL by $2\pi \tanh kd$, or $L = gT^2$ by $2\pi \tanh kd$. Since the unknown L occurs on both side of equation 2.32 it has to be solved by trial and error because k is nothing but 2π by L . So, if you this, you want to, so, this is the equation dispersion famous dispersion equation, sigma squared =

$g k \tanh k d$ which you must remember and doing some no manipulation here and there we can also write $L = gT^2 \text{ square by } 2 \pi \tanh k d$.

And this is also a different form of dispersion relationship and because this L appears on both sides of this equation 2.32 this equation if needs to be solved will be solved by trial and error method.

So, I will stop at this point in this lecture and when we start the next lecture, we are going to study the celerity in different water depth conditions. So, thank you so much for listening in this lecture and I will see you in the next class.
