**Soil Exploration - III**

So, last class I have discussed about different penetration test SPT and SCPT and DCPT and then I have discussed different correlations by which you can determine the soil properties.

So, today I will discuss about the pressure meter test.

**(Refer Slide Time: 00:50)**

**Pressuremeter Test**

- The pressure meter consists of an inflatable cylindrical probe which is connected to a water reservoir.
- Expand cylindrical probe inside a bore hole.
- The probe presses against the wall of bore hole. So the soil begins to deform
- The volumetric deformation of the borehole is measured by noting the fall in water level in the water reservoir

IS: 1892-1979 describes the use of pressure meter

<https://www.youtube.com/watch?v=Cpb2R232nuk>

N Sivakugan

The diagram illustrates the pressuremeter test setup. It shows a vertical borehole in a soil mass. A cylindrical probe is inserted into the borehole, flanked by two guard cells. The probe is connected to a water reservoir at the top. A video inset shows a person speaking, and a small image shows the physical pressuremeter instrument.

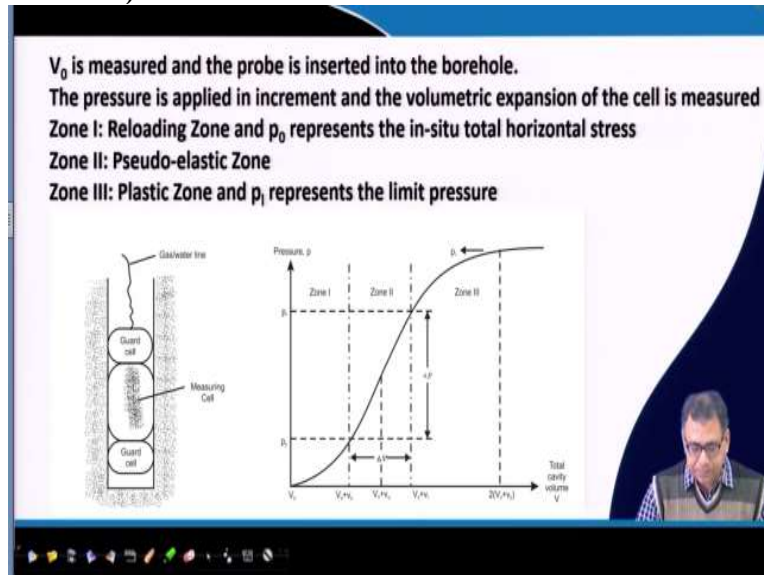

So, the pressure meter test is another in-situ test by which we can measure different soil properties by using the correlations. So, this is the pressure meter instrument so, it has a cylindrical probe and 2 guard cells. So, these guard cells are used to protect this probe within the borehole. So, here also we need the borehole and here the pressure meter consists of an inflammable cylindrical probe.

So, this is connected to a water reservoir so, that means this probe can be expanded so, we apply the water pressure then this probe expands and we measure the volume change. So, this is the mechanism by which we can measure the properties. So, that means we apply the pressure and this probe expands. So, that means it expands and soil starts to deform. So, then we measure this expansion.

And corresponding pressure or you can say the pressure corresponding the expansion that means, the volume expansion we measure so, this cylindrical probe we place it inside a

borehole, then when you apply the pressure the soil begins to deform and this probe volume increases. So, we measure basically pressure versus volume plot or we do the pressure versus volume plot, we measure pressure and the volume change. So, volumetric deformation of the borehole is measured by noting the fall in water level in the water reservoir that means, we measure the fall in water level or basically the pressure and the volume.

(Refer Slide Time: 03:16)

So, now, as I mentioned this is the pressure and the volume change. So, this is the plot that you will get from that test. So, that means, from this curve, we can see this curve has 3 different zones. So, what are the 3 zones? Initial volume of the probe that is  $V_0$  that we can measure generally is this  $V_0$  is  $535 \text{ cm}^3$ . So, that is known, so,  $V_0$  is known for us.

So, this  $V_0$  is the starting point which is known and initial pressure is say 0 and now, we will start applying pressure so, now the volume of the probe will increase from  $V_0$  to certain value and pressure also increases. So, then we will get these 3 zones. So, initially, we do not have these zones and we have to identify these zones. So, we have this graph. So, that once we get this graph say suppose initial period, we will get in some portion this pressure versus volume change is linear.

So, we identify these 2 points, the starting points and ending points, the starting points where this linear zone starts and the end points where this linear zone ends. So, I mean this linear behavior we have to identify these 2 points. So, we will identify these 2 points and the corresponding volume is  $V_0 + v_0$ . That means and corresponding pressure is  $p_0$  that means to reach this point the volume change is  $v_0$ .

And then the another point corresponding pressure is  $p_f$  and the corresponding volume change is  $V_0 + v_f$ . So, that means the volume change is  $v_f$  to reach this  $p_f$  and this is the middle point which is  $v_0 + v_m$ . So, that means to reach this first point the volume expansion is  $V_0$  total volume is  $V_0 + v_0$  and the second point the volume expansion is  $v_f$ .

So, the first zone is called reloading zone and  $p_0$  represent in-situ total horizontal stress why this zone is called reloading zone? Because when we construct the borehole that means the pressure on the soil is released. So, some deformation of the soil will take place towards the borehole. Now, this is not the actual condition because now the soil condition is been disturbed and some deformation of the soil takes place towards the borehole or you can say inside the borehole towards the borehole centre.

So, some soil deformation has been taken place. Now, once we apply the pressure and the probes starts to deform then it will push that deformed soil to its original position. So, this first point, so, at  $v_0$  position the soil will go to its original position. So, that is why it is this pressure  $p_0$  is called in-situ total horizontal stress because that is the in-situ condition of the soil because now the soil initially was disturbed, now we apply the pressure now the probe expands.

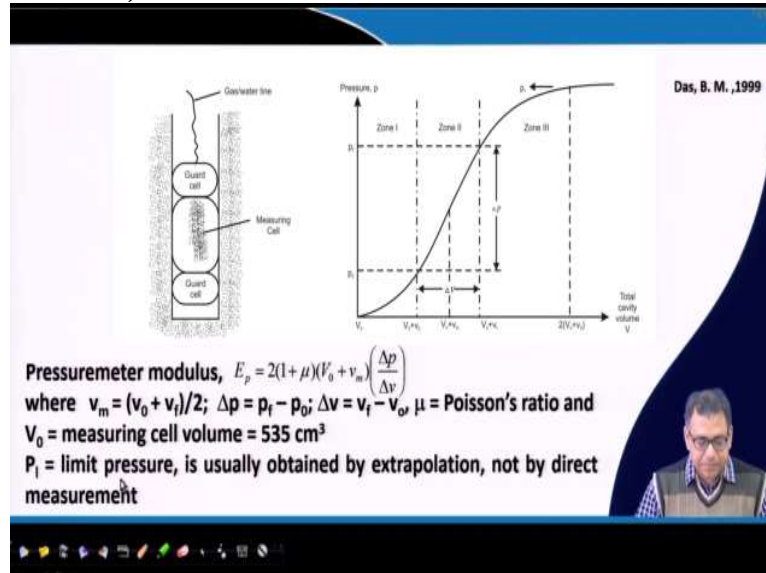

So, now it reaches its initial condition due to this  $V_0$  volume change at  $p_0$  pressure so, this is called a reloading zone. Now, the next one is called a pseudo elastic zone because here the pressure versus volume change relation or volume relation is linear and third zone is called a plastic zone and  $p_l$  represent the limit pressure now, how I will get this  $p_l$ ? Now,  $p_l$  I will get in 2 ways one is that if because during this test I will get this plot I will get this  $V_0 + v_0$  value.

Now, I have to continue the test up to 2 times  $V_0 + v_0$  and they are in the test so that corresponding pressure is the  $p_l$  or the second option is that suppose your instrument has some limits, so, you cannot go beyond some pressure or some volume change. So, there you have to stop your test. So, that may be the list and 2 times  $V_0 + v_0$ . So, now in such case how I will get the  $p_l$ ?

Because if my test ends before these are 2 times  $V_0 + v_0$ , then how I will get that  $p_l$ ? Because that time I have to get that  $p_l$  by interpolating it. So, that means in the plot, I will identify the point corresponding to 2 times  $V_0 + v_0$  and then I extend this graph. So, that is interpolation because I may not measure that value because of the limitation of the equipment.

But I can interpolate these and I can extend this curve up to that point that corresponding to this point and then I can find out the  $p_l$  value. So, if I can go up to that point, I can measure but most of the cases it is not possible to go up to that point. So, I have to finish the test before that point. So, I can interpolate that and I can locate the  $p_l$  value, which is called as limit pressure.

**(Refer Slide Time: 10:13)**

So, now, from these values I will get the pressure meter modulus, which is the  $E_p$  that value I will get this is the  $\Delta p$ ,  $\Delta p$  is the difference between  $p_0$  and  $p_f$  or  $p_f$  and  $p_0$  and  $v$  is the  $v_f - v_0$  that is  $\Delta v$  and then  $V_0$  I know that is 335 cc most of the cases  $\mu$  is the Poisson ratio of the soil so, I will get the pressure meter modulus  $E_p$  and as I mentioned the  $p_l$  limit pressure is usually obtained by or this is extrapolating because not the interpolation it is extrapolation.

Because it is outside the plot so, it is extrapolation of the plot so, it is not interpolation. So, correct this it is extrapolation because I have to extend this because maybe your test ends here. So, you have to extrapolate these plots so, this is the extrapolation because you have to extrapolate this plot up to this point, but not direct measurement.

**(Refer Slide Time: 11:24)**

**Correlations**

$$c_u = \frac{p_l - p_0}{N_p} \quad (\text{Baguelin et al. 1978})$$

where  $c_u$  is undrained shear strength of clay

$$N_p = 1 + \ln\left(\frac{E_p}{2c_u}\right)$$

Typical values of  $N_p$  vary between 5 to 12 (average = 8.5)

$E_p (kN/m^2) = 908N^{0.66}$	For Clay	} Ohya et al. 1982, also Kulhawy and Mayne, 1990
$E_p (kN/m^2) = 1930N^{0.63}$	For Sand	

where  $N$  is standard penetration (SPT) value

Das, B. M., 1999

So, again once you get this  $E_p$  and  $p_l, p_0, p_f$  then again we have to use these values in correlations to get the soil properties again I can get the undrained shear strength or the correlation that expression is  $\frac{p_l - p_0}{N_p}$ . So,  $p_l$  I have already discussed  $p_0$  also I have discussed and this  $N_p$  I will get by using this equation and  $E_p$  I will get by this equation and I will put it here, but in that case, there will be a  $c_u$  and there is also  $c_u$ .

So, by trial and error I can get the  $c_u$  value there is only one or none, but the solution is very complicated. So, we can use that trial and error you will get the  $c_u$  if you use here because here  $E_p$  will be given by the equation and  $c_u$  I will get from this equation. Another case directly if you use the  $N_p$  which varies from 5 to 12 average 8.5 then also I will get the  $c_u$  and  $E_p$  value I can also correlate with the SPT  $N$ . So, that also I can correlate for clay and the sand. The pre consolidated pressure also  $p_c$  I can get by using this correlation up into  $p_l$  and pre consolidation pressure also I can get.

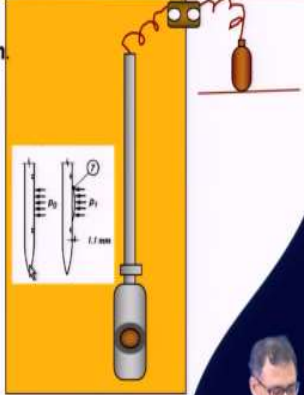

**(Refer Slide Time: 12:53)**

**Dilatometer Test**

- ◆ Advance @ 20 mm/s. Test every 200-300 mm.
- ◆ Nitrogen tank for inflating the membrane.
- ◆ Gives  $c_u$ ,  $K_0$ , OCR,  $c_h$ ,  $k_h$ , soil stiffness.
- ◆ Can identify soil.

60 mm diameter flexible steel membrane

<https://www.youtube.com/watch?v=E8hq-dLN1Fo>

N Sivakugan

Now, the next test is the dilatometer test. So, the dilatometer test also here bore hole is not required, here the instrument is pushed into the soil at a rate of 20 millimeter per second and we test every 20 to 30 millimeter interval and pressure meter we use the water but here the nitrogen tank is used or nitrogen is used for inflating the membrane. Here also is similar to pressure meter, but the difference is that here there will be a flexibility steel membrane in this equipment.

And that can we have to use the nitrogen for inflating this membrane, so this membrane will inflate and we will get the deformation or the reading and the corresponding pressure we can measure. So, that means similar to the pressure meter test, also we measure the pressure and the volume change. Here also we will measure the expansion of these or inflation of the membrane and the pressure.

So, it will give us the undrained coefficient  $K_0$  value that when the coefficient of pressure air pressure condition over consolidation ratio, then  $c_h$  coefficient of consolidation in horizontal direction  $k_h$  permeability in horizontal direction soil stiffness, it can identify the soil also. So basically, it has 2 major readings. Actually, it has 3 readings but these 2 major readings we will use for the correlations. So, one reading is called A reading and the next one reading is called the B reading.

So, in A reading I will get the  $p_0$  and B reading I will get the  $p_1$ , there is another reading C reading there I will get the  $p_2$ , but that will not discuss here. So, here I will get the  $p_0$  by taking

A reading and  $p_l$  by taking the B reading. So, it is A reading B reading are different stages by which we are taking different readings.

(Refer Slide Time: 15:30)

**Marchetti (1980)** **Mainly for Clay ( $I_p < 1.2$ )**

$K_0 = \left(\frac{K_D}{1.5}\right)^{0.47} - 0.6$  Horizontal stress index  $K_D = \frac{p_0 - u_0}{\sigma'_{v0}}$  **Material Index**

$c_u = 0.22\sigma'_{v0}(0.5K_D)^{1.25}$  Dilatometer Modulus  $E_D (kN/m^2) = 34.7(p_l - p_0)$

$OCR = (0.5K_D)^{1.56}$  (NC clay,  $K_D=2$ ) \* $p_0$  is the contact stress i.e the pressure required to just begin to move the membrane

$\frac{c_u}{\sigma_v} = 0.22$  Normally consolidated clay \* $p_l$  is the expansion stress i.e pressure required to move the centre of the membrane by 1.1 mm into the soil

$\left(\frac{c_u}{\sigma_v}\right)_{\text{over consolidated clay}} = \left(\frac{c_u}{\sigma_v}\right)_{\text{normally consolidated clay}} (0.5K_D)^{1.25}$  \* $u_0$  is the pore water pressure

$E = (1 - \mu^2)E_D$  Das, B. M., 1999

$\sigma'_{v0}$  (or  $p_0$ ) is the vertical effective overburden pressure or stress

E is the elastic modulus

$K_0$  is the coefficient of earth pressure at rest

$\mu =$  Poisson's ratio

*(Diagram showing a soil sample with a membrane and stresses  $p_0$  and  $p_l$  applied, with a 1.1 mm displacement indicated.)*

So, once we get these readings, we use these correlations for different types of soil. So, what is that so, here first let me explain what is  $p_0$  and  $p_l$ ? So, as I mentioned  $p_0$  is the contact stress that is the pressure required to just begin to move the membrane. So, that means here  $p_0$  or the A reading where we have to apply the stress that initially when we apply the stress immediately the movement of the membrane will not take place, we have to apply some reading so, that at that point the membrane will start deform.

So, that the  $p_0$  is the pressure required just to begin the membrane to move so, that is our A reading and  $p_l$  is the expansion stress that is the pressure required to move the center of the membrane by amount of 1.1 millimeter into the soil. So, that means  $p_l$  is the pressure that we will measure where the membrane will deform by 1.1 millimeter the membrane center will deform by 1.1 millimeter into the soil and  $u_0$  is the pore water pressure.

So, it is clear what are  $p_0$  and  $p_l$ ?  $p_0$  is the pressure required to just begin to move the membrane and  $p_l$  is the pressure required to move the center of the membrane by 1.1 millimeter into the soil. So, once I get this  $p_0$  and  $p_l$  and  $u_0$ , I calculate then I will get different properties. So, that will first one is the horizontal stress index. So, this is  $K_D$ ,  $K_D$  is the  $\frac{p_0 - u_0}{\sigma'_{v0}}$ ,  $\sigma'_{v0}$  is the effective vertical overburden pressure.

So, if I know the  $u_0$  if I know the  $\sigma'_{v0}$  and  $p_0$  from here I will get the  $K_D$  then I will get the dilatometer modulus this is  $E_D$ ,  $E_D$  is  $34.7(p_l - p_0)$ . So, once I get the  $K_D$  and  $E_D$  then I will get these properties for the clay. So, those properties this is mainly for clay those properties are  $K_0$ ,  $K_0$  is the coefficient of earth pressure at rest. So, this is the expression correlation then undrained coefficient this is the expression  $K_D$ .

Again, this is effective overburden pressure then over consolidation ratio is  $(0.5K_D)^{1.56}$ . So, you can see that for normally consolidated clay  $K_D$  value is equal to 2. So, if your soil has a  $K_D$  value of 2 then we can say this is a normally consolidated soil and if it is more than 2 then it will be over consolidated soil. So, for normally consolidated soil this is the correlation.

So, if I get the undrained cohesion for the normally consolidated soil by using these correlations then I can use this correlation to get the undrained cohesion for over consolidated clay also. So, that is done normally consolidated clay into  $(0.5K_D)^{1.25}$  this is into. So, this is actually this value is this is into. So, then I will get the elastic modulus by using these expressions also  $\mu$  is Poisson ratio and  $E_D$ , I will get from here.

So, these correlations are for the clay that means the  $K_0$ ,  $c_u$ , OCR,  $E$  and then  $c_u$  I can get for a normally consolidated clay and for over consolidated clay also we can get so, this  $c_u$  depending upon  $K_D$  value I can get whether it is a over consolidated soil or normally consolidated soil. So, if it is a normally consolidated clay directly, I can use these expression and over consolidated soil I have to use these expressions.

**(Refer Slide Time: 20:28)**

**Horizontal Coefficient of Consolidation and permeability of soil** **Mainly for Clay**

**Point of contraflexure**

**Horizontal Coefficient of Consolidation**

$$c_h \approx \frac{7 \text{ cm}^2}{t_{flex}}$$

**Horizontal Coefficient of Permeability (Schmertmann, 1988)**

$$k_h = \frac{c_h \gamma_w}{M_h}$$

where  $M_h \approx K_0 M_{DMT}$

Failmezger, R. A. and Anderson, J. B. (2006) Proceedings from the Second International Conference on the Flat Dilatometer, Washington, D.C., April 2-5, 2006.

Now, next one is to determine the horizontal coefficient of consolidation and the permeability of the soil and these correlations are also for clay. So, previous correlations are also for clay these correlations are also for clay. So, I will get the horizontal coefficient of consolidation so, that is  $c_h$  so, that is equal to  $\frac{7 \text{ cm}^2}{t_{flex}}$ . So, the  $t$  can be second or minute so, that means the  $c_h$  will be either 7 centimeter square by second or 7 centimeter square by minute depending upon which how you are putting  $t_{flex}$  value.

Now, what is  $t_{flex}$ ? So, here as I mentioned that during this test, we are taking 2 readings one is your A reading and another is your B reading, A reading will give you  $p_0$  and B reading will give you  $p_1$ . So, here we will go for the A reading only. So, this is the A reading that is why so, this is the pressure that you will give during the A reading. So, that A reading will take and you will off this B reading I mean B reading will not take we will keep this instrument under A reading condition.

And we will take the reading at different time intervals clear. So, that means we will keep the instrument under A reading condition and then at this condition will keep on taking this reading with different time intervals. So, these are the different time intervals you can see this 1 day, 1 week and we can take this 1 minute then 5 minutes then 10 minutes. So, different time intervals we will take the reading and so and we will plot these readings with time this is  $x$  axis is time in minute and  $y$  axis is the A reading so with time.

And then we will identify there will be a change in curvature in the curve you can see so, this is the curvature and then there is a change in curvature. So, this is one curve and then it is the change so, we have to identify that point. So, that point and the corresponding time will give me the  $t_{flex}$ . So, this is called point of contraflexure and this is small  $t_{flex}$ . So, these points of contraflexure we have to identify by plotting this A reading and the time.

So, this is the point of contraflexure and that means where your curvature changes to identify that point and the corresponding time will give me the  $t_{flex}$ . So, you put this and you will get the horizontal coefficient of consolidation. Now, the horizontal coefficient of permeability I will get by using this expression this is  $c_h$  I will get from this expression then  $M_h$ ,  $M_h$  is the  $K_0 \times M_{DMT}$ . So,  $K_0$  it is the coefficient of earth pressure at rest that I will get by using this

expression  $K_0$  I will get then  $c_h$  also I will get from these expression. This is  $\gamma_w$  is unit weight of water and  $M_{DMT}$  I will explain what is  $M_{DMT}$ ?

(Refer Slide Time: 24:56)

**Vertical Drained Constrained Modulus ( $M_{DMT}$ ) =  $R_M E_D$**

Now,  
 if  $I_D \leq 0.6$ , then  $R_M = 0.14 + 2.36 \log K_D$  where  $I_D$  is the Material Index:  $I_D = \frac{p_1 - p_0}{p_0 - u_0}$   
 if  $I_D \geq 3$ , then  $R_M = 0.5 + 2 \log K_D$   
 if  $0.6 < I_D < 3$ , then  $R_M = R_{M0} + (2.5 - R_{M0}) \log K_D$   
 where  $R_{M0} = 0.14 + 0.15 (I_D - 0.6)$

Note:  
 if  $K_D > 10$ , then  $R_M = 0.32 + 2.18 \log K_D$   
 if  $R_M < 0.85$  take  $R_M = 0.85$

**For Sand**

$0.1 < I_D < 0.6$	Clay
$0.6 < I_D < 1.8$	Silt
$1.8 < I_D < 10$	Sand

Note: penetration resistance of the blade tip:  $q_D \approx q_c$

Now,  
 For NC sand:  $M_{DMT} / q_c = 5$  to  $10$   
 For OC sand:  $M_{DMT} / q_c = 12$  to  $24$   
 Thus, first determine  $M_{DMT}$  and  $q_c$  (cone resistance, can be obtained from Static Cone Penetration Test). Based on the range of the  $M_{DMT} / q_c$  value it can be identified whether the sand is NC or OC.

Now for this  $M_{DMT}$  which is drained constraint modulus of the soil the constraint modulus is generally  $1 / M_B$ ,  $M_B$  is the coefficient of volume change. So, and this  $M_{DMT}$  will get  $R_M \times E_D$ ,  $E_D$  I will get from these expressions and how I will get the  $R_M$ . So,  $R_M$  I will get by using these conditions so, to get the  $R_M$  we have to identify the  $I_D$  which is called material index.

So,  $I_D$  I will get by using these expression  $\frac{p_1 - p_0}{p_0 - u_0}$ . So,  $p_1$ ,  $p_0$ ,  $u_0$  I have already explained so, this  $I_D$  I have to calculate material index based on this  $I_D$  I can identify the soil type also if your,  $I_D$  is less than 0.6 and greater than 0.1 then it is clay if it is less than 1.8 and greater than 0.6 then it is silt if it is within 1.8 to 10 then it is sand. So, here in previous expression as I mentioned it is valid for  $I_D$  less than 1.2.

So, it is mostly clay because clay is 0.6 some silt is also there, because it is less than 1.2 but it is mostly clay. But if these expressions if we have to use if  $I_D$  is greater than 1.8 then only those expressions are valid for sand if your,  $I_D$  is greater than 1.8 because that is then only your soil is sand otherwise soil is not sand. So now by these conditions  $I_D$  I can calculate for clay  $I_D$ , I can calculate for silt  $I_D$ , I can calculate for sand also now, if your,  $I_D$  is less than equal to 0.6 that means it is clay then  $R_M$  will be this equation.

So, I will get the  $R_M$  for the clay by this equation, this is the  $K_D$  this is  $\log 10 R_M$  and I will put  $R_M$  here and I know the  $E_D$  I will get the DMT and that DMT I will put it here I will know your

$K_0$  I will know the  $M_h$  and that  $M_h$  I will put it here I will give the  $K_h$  the horizontal coefficient of permeability is it clear. Now I will go for the sand part. So previous correlations are valid for the clay these correlations are valid for the clay, mainly clay, now I go for the sand part.

But if your,  $I_D$  is greater than 3 then which is basically sand then  $R_M$  can be obtained by using this expression. If it is in between 0.6 to 3 then  $R_M$  will be obtained by using this expression now here what is  $R_{M0}$ ?  $R_{M0}$  can be obtained by using these expressions. Now I can obtain the  $R_M$  for clay, silt and sand depending upon  $I_D$  value. Now note that if your  $K_D$  is greater than 10 then you have to use these equations because this is the based on the  $I_D$  but these are the 2 special cases.

Suppose if your  $K_D$  is greater than 10 then directly we use  $R_M$  can be obtained by using this expression then  $I_D$  classification or  $I_D$  different types of  $I_D$  are not required. So, if your  $K_D$  is 10 so that means initially you check what is your  $K_D$  value if your  $K_D$  value is greater than 10 directly you use this  $R_M$  expression. Now if your  $K_D$  is less than 10 then you based on different  $I_D$  you calculate the  $R_M$  clear?

If your  $K_D$  is greater than 10 using this expression and if your  $K_D$  is less than 10 then based on different  $I_D$  value you will get the different  $R_M$  value and another condition is that if by any chance by above expression is giving the  $R_M$  less than 0.85 then you take  $R_M = 2.85$  your  $R_M$  cannot be less than 0.85,  $R_M$  you have to take 0.85 or more. So, now for it is very difficult to identify whether sand is in normally consolidated state or the over consolidated state.

Because in clay you can do the odometer test and you can identify what is the  $P_C$  and whether you can identify the soil is because you can identify the  $P_C$  which is very important to understand whether soil is in over consolidated state or the normally consolidated state but in the sand doing odometer test is difficult because of its disturbance. So, here by the dilatometer test approximately we can identify whether sand is in over consolidated state or normally consolidated state.

How we can do that? Because once we get the  $R_M$  for sand, then also we will multiply with  $E_D$ , I will get the  $M_{DMT}$ . So, then that  $M_{DMT}$  we divide it with the  $q_c$  that mean the cone resistance that means the static cone penetration test I will get that value I have already discussed the static cone penetration test. So, therefore the static cone penetration test I will get the  $q_c$  and

that  $M_{DMT}$  divide the  $q_c$  now for normally consolidated sand the  $M_{DMT} / q_c$  is within 5 to 10 and for over consolidated sand this varies from 12 to 24.

So, based on the  $I_D$  value, we have to calculate the  $R_M$  and that  $R_M$  we will put it here we will get the  $M_{DMT}$  and then we will divide by the  $q_c$  then we will identify based on these range whether soil is in normally consolidated state or over consolidated state. So, this way we can identify that.

**(Refer Slide Time: 32:30)**

**For Sand**

Assumed cone roughness 1.8-0.15

The graph shows the relationship between  $\frac{\phi}{\sigma'_{v0}}$  (y-axis, 10 to 1000) and  $K_0$  (x-axis, 0.2 to 8). Curves are plotted for various values of  $\phi$  (24, 25, 26, 28, 30, 32, 34, 36, 38, 40, 42, 44).

So, now, in the next one for the sand also you can calculate the  $K_0$  by using this expression, these  $q_c$  this is the cone resistance that I will get the static cone penetration test that is  $\sigma'_{v0}$  that means effective overburden pressure. Now, I can get the  $\phi$  also by using this expression, I can get the  $\phi$  by using these curves also because I can get the  $K_0$  by using this equation.

If I know the  $q_c$  and effective overburden pressure then I can get the  $\phi$  value also for the soil. So, either I can use this chart or I can use the expression to get the  $\phi$  value of the soil. So, here in next class I will discuss a few more in-situ tests by which we can determine the soil properties. Thank you.
