**IIT Hyderabad**

Welcome back to structural dynamics class. So in this module we will study about dynamic amplification factors. So last class we have studied about damped forced vibration and undamped forced vibrations. So as we have noticed in that is, when forcing frequency and the natural frequency of the system matches a resonating condition is taking place. So in this resonating condition amplitudes have displacement, amplitude of velocity and amplitude of acceleration will go to very high values.

So sometimes up to infinity or very large values, so because of the presence of damping we can reduce this amplitude to a greater extent, but let us understand the relationship between these response dynamic amplification factor for displacement, velocity and acceleration in this class. So how we are sensitive to frequency ration and like where do we apply all those things we will study in this class.

(Refer Slide Time: 01:23)

**Outline**

- Dynamic Response Factor for displacement
- Dynamic Response Factor for velocity
- Dynamic Response Factor for acceleration
- Dynamic Response Factor
- Special Cases
- Summary

2

So the outline of this class is dynamic response factor for displacement we will understand, response factor for velocity we will understand, dynamic response factor for acceleration we will understand. We will try to derive the relationship between these three factors displacement, response as well as acceleration. Now if we look at the equation of motion.

(Refer Slide Time: 01:42)

**Dynamic Response Factor for Displacement**

$$m\ddot{u}(t) + c\dot{u}(t) + ku(t) = P_0 \sin \omega t$$

**Steady State Amplitude**

$$u(t) = u_{st} R_d \sin(\omega t - \phi)$$

So which consists of three terms that is inertia term, damping term and stiffness term. So all these are not together is equal to the external force which is dynamic in nature.  $P_0$  is the amplitude of the force and  $\omega$  is the forcing frequency. Now if we look at the study state amplitude which we have studied, which we have understood in the last class, so study state amplitude is the product of static displacement and dynamic amplification factor for displacement as well as the sinusoidal component.

So in this we need to observe the presence of this  $\phi$ , this  $\phi$  is a phase angle. So its phase angle means like the way the force is getting applied and the way displacement is taking place, so are they in phase or are they out of phase. So in phase means when we apply force displacement also will be in the same direction, but out of phase means when we apply force displacement will be in the opposite direction. So these conditions also we will try to understand in this.

(Refer Slide Time: 02:47)

**Dynamic Response Factor for Displacement**

$$m\ddot{u}(t) + c\dot{u}(t) + ku(t) = P_0 \sin \omega t$$

**Steady State Amplitude**

$$u(t) = u_{st} R_d \sin(\omega t - \phi)$$

$u_{st} = \frac{P_0}{k}$

$$\frac{u(t)}{u_{st}} = R_d \sin(\omega t - \phi) \text{ Eq. (1)}$$

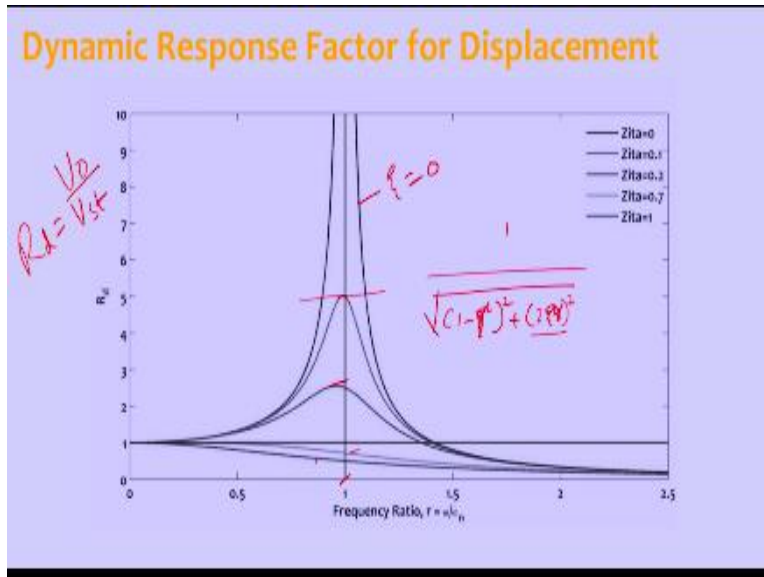

$R_d =$  Deformation Response factor

It is the ratio of amplitude  $U_0$  of dynamic deformation to static deformation,  $U_{st}$

Now if we look at this one so dynamic displacement divided by static displacement is equal to  $R_d \times \sin\omega t - \phi$ , but if you take only amplitude it becomes this, this much portion amplitude. So this  $R_d$  is called deformation response factor or dynamic response factor for displacement. So it is a ratio of  $U_0$  that is amplitude of dynamic deformation to static deformation.

So we know that static deformation can be found out by amplitude of the load divided by stiffness, this is static deformation. So dynamic deformation is it more than the static deformation, less than static deformation, so what are the cases which increases, decreases this dynamic deformation compared to static deformation we will try to understand.

(Refer Slide Time: 03:41)

Now if we plot this curve  $R_d$ , so that  $R_d$  is  $U_0/U_{st}$  and this  $R_d$  is the equation is  $1/\sqrt{(1-r^2)^2 + 2\zeta^2 r^2}$  sorry  $1/\sqrt{(1-r^2)^2 + 2\zeta^2 r^2}$ . So if you substitute  $R$  in this one  $r$  value from 0 up to say 2.5 will get this response so this response is for different damping value so this the first this one is  $\zeta$  value is equal to 0 and here  $\zeta$  value is 0.1, 0.2, 0.7 and  $\zeta$  100% damping and you can see in this curve we can see that at when  $r = 1$  in this if I substitute  $r = 1$  and when  $\zeta = 0$ .

So this term will disappear and it we will be left with only  $1 - r^2$  when  $r$  is one this will become 0 so that means the amplitude  $R_d$  value will be infinity and when we introduce say 10 % damping, 20% damping something like that so suddenly this amplification that peak value will be it is getting reduced this is dynamic amplification factor for displacement.

(Refer Slide Time: 05:15)

**Dynamic Response Factor for Velocity**

$$\frac{u(t)}{u_{st}} = R_d \sin(\omega t - \phi) \quad \text{Eq. (1)}$$

**Differentiating Eq.(1)**  $\frac{\dot{u}(t)}{P_0/k} = R_d \omega \cos(\omega t - \phi)$

**Dividing both side by  $\omega_n$**   $\frac{\dot{u}(t)}{(P_0/k) \times \omega_n} = R_d \frac{\omega}{\omega_n} \cos(\omega t - \phi)$

$$\frac{\dot{u}(t)}{(P_0/k) \times \sqrt{\frac{k}{m}}} = R_d r \cos(\omega t - \phi)$$

$$\frac{\dot{u}(t)}{(P_0/\sqrt{km})} = R_d r \cos(\omega t - \phi)$$

$R_v = r R_d$

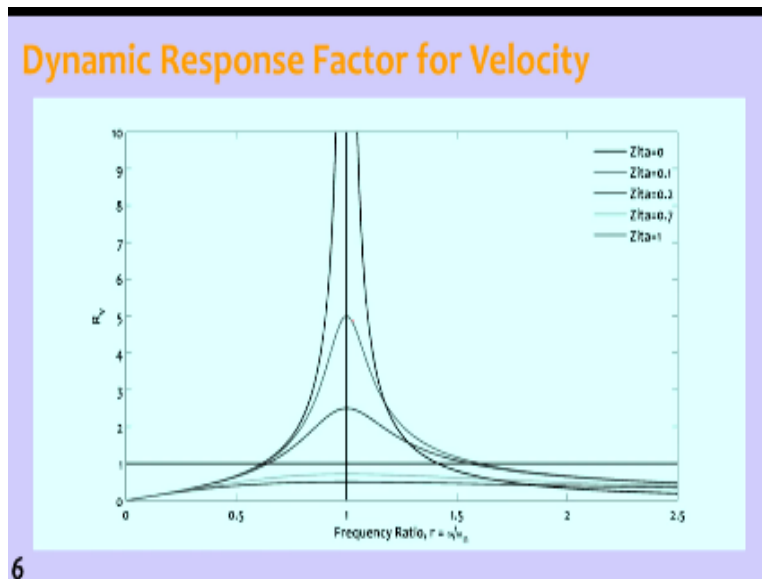

**$R_v$  = Velocity Response factor**  
**It is the ratio of amplitude of dynamic velocity to static velocity**

5

Now dynamic amplification factor for velocity so as we know this is an equation so u dynamic displacement divided by static displacement is equal to  $R_d$  multiplied by sinusoidal path that is  $\omega t - \phi$  so if we differentiate this equation then what we get is so on a numerator we get velocity and here if we differentiate one  $\omega$  comes out of that  $\sin \omega t - \phi$  so  $\omega$  and the  $\cos t$  it will remain so  $U_s(t)$  is nothing but  $P_0$  by amplitude by stiffness.

So if you rearrange this terms and by dividing by  $\omega_n$  so what we get is this  $\omega/\omega_n$  will remain and this  $P_0/k \times \omega_n$  so if we rearrange this one  $\omega_n$  is under root  $k/V_0$   $\omega/\omega_n$  is a ratio of frequencies so  $R = \omega/\omega_n$  it is ratio of a frequencies so we can write that  $u./P_0/\sqrt{km} = R_d$  multiplied by  $R \times \cos \omega t - \phi$  so what we can look at is, you can see this one  $u.t$  so  $u.t$  means velocity okay in that so this term can be treated as  $R_v$  so this is called dynamic response factor for velocity it is a ratio of amplitude of dynamic velocity to static velocity is like  $R_v$  so dynamic velocity and this is static velocity.

(Refer Slide Time: 06:56)

So the graph if we plot this in the graph what we will get is like this okay again in this one you can see when damping is not there this value goes to infinity and with the presence of damping that peak amplitude drastically reduces.

(Refer Slide Time: 07:12)

**Dynamic Response Factor for Acceleration**

$$\frac{u(t)}{u_{st}} = R_d \sin(\omega t - \phi) \quad \text{Eq. (1)}$$

**Double Differentiating Eq.(1)**  $\frac{\ddot{u}(t)}{\left(\frac{P_0}{\sqrt{km}}\right)} = -r R_d \omega \sin(\omega t - \phi)$

**Dividing both sides by  $\omega_n$**   $\frac{\ddot{u}(t)}{\left(\frac{P_0}{\sqrt{km}}\right) \sqrt{\frac{k}{m}}} = -r^2 R_d \sin(\omega t - \phi)$

$$\frac{\ddot{u}(t)}{\left(\frac{P_0}{m}\right)} = -r^2 R_d \sin(\omega t - \phi)$$

**$R_a =$  Acceleration Response factor**  
**It is the ratio of dynamic acceleration to static acceleration**

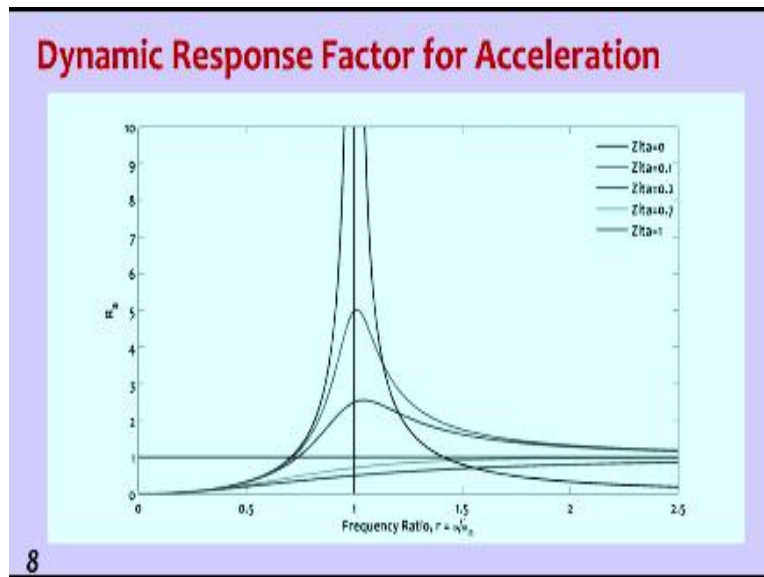

**7**

And then in the similar manner let us go further and analyze dynamic amplification factor for acceleration so the same equation if we take but now we will differentiate it twice so if we do it twice what we will get is  $\ddot{u}$  on the numerator and here if you look at this  $k$  filling  $R_d$  multiplied by we need to do twice so  $\omega^2$  down will come so  $1/\omega$  came down here so another  $\omega$  is remains here can see if you divide by  $\omega_n$  so what we get is  $\ddot{u} \cdot \sqrt{k/m}$  and again  $\sqrt{k/m}$  because of  $\omega_n$  natural frequency return by natural frequency.

We get  $R^2 R_d \sin \omega t - 1$ , so this negative sign can be removed because we are testing the amplitude only so now  $\ddot{u}$ ,  $\ddot{u} \cdot \sqrt{k/m}$  we using this equation. If you look at it, then  $-r^2 R_d \sin \omega t - \phi$ , so in this one so this term can be treated as  $R_a$  dynamic amplification factor for acceleration so  $R_a$  is acceleration response factor it is a ratio of dynamic acceleration to static acceleration values.

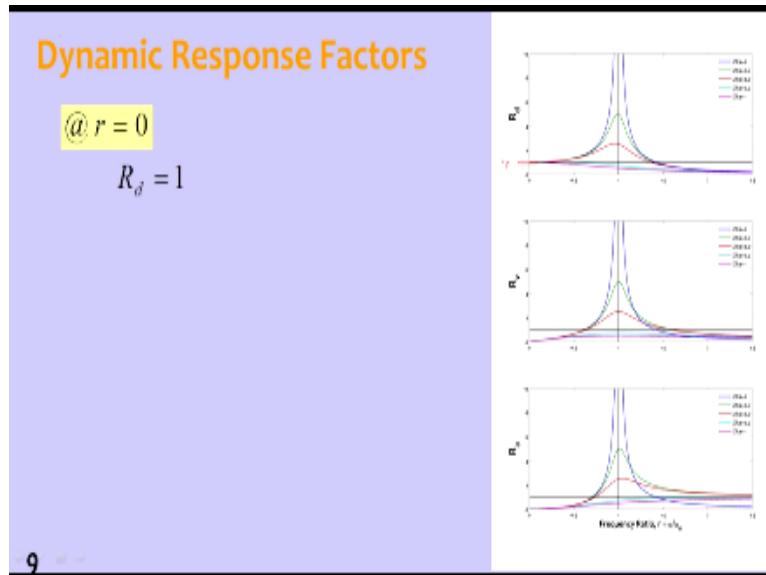

(Refer Slide Time: 08:27)

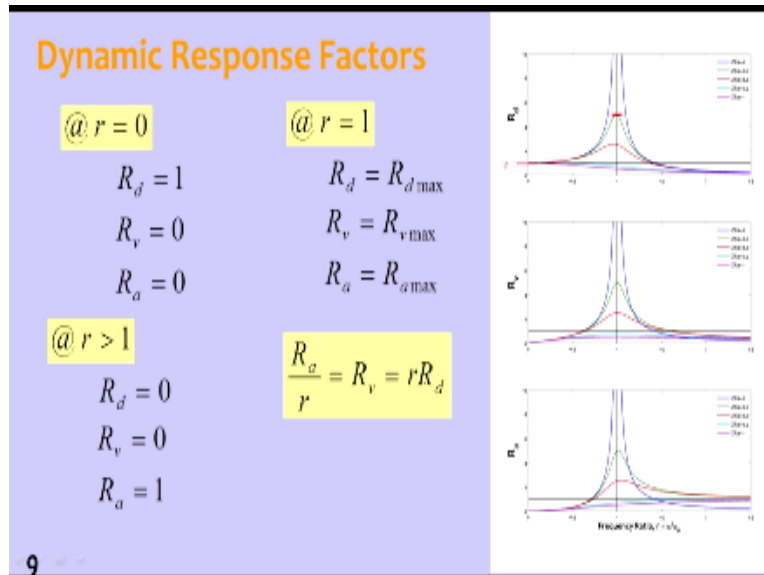

Now if we look at the plot of this dynamic acceleration we get the similar plot but there are some changes I will explain this changes little while later.

(Refer Slide Time: 08:35)

Now if you look all three at a time, okay so these graphs look quite similar but when we observe it we will find the differences so at  $r=0$ ,  $r=0$  means it is slowly varying force or static force at this location when  $r=0$  what is happening to  $R_d$ ,  $R_v$  and  $R_a$  let us look at that.  $R_d$  is starting from 1 you can see this, this value is 1 so that means what when the body I can see this one let us take entire beam and a person or say a moving mass is, moving weight is there so if it is standing here  $r$  is less means it is static, static means directly deflection will be there, so ratio of static deflection to dynamic deflection is 1 only, so that is equal to static deflection again.

(Refer Slide Time: 09:27)

And if you look at  $R_v$  velocity since there is mass is not moving that force is not moving  $R_v$  will be 0 and similarly  $R_a$  will also be 0, so at  $r=0$  at lower frequencies or at rest condition  $\omega/\omega_n$  that  $\omega$  is 0 or nearly equal to 0 we get  $r=0$ , so  $R_d=1$ ,  $R_v=0$ ,  $R_a=0$ . When we go to exchange values okay, or when we come to resonating frequencies what is going to happen. Resonating frequencies along with damping  $R_d=R_{d\text{MAX}}$  value so something like this at this location.

And then  $R_v$  is  $R_{v\text{MAX}}$  and  $R_a$  is  $R_{a\text{MAX}}$  so a point need to be observed in this one is all this  $R_{d\text{MAX}}$ ,  $R_{v\text{MAX}}$  and  $R_{a\text{MAX}}$  values they are not occurring exactly at the same value but they are nearly maximum at that value, nearly maximum. Because of that results of damping that slightly shifts slightly away from this one mark, and when  $r$  value is much, much greater than 1 so that means  $r$  is a 10, 20 something like that.

So what happens is  $R_d$  goes to 0 you can see here, so at larger values  $R_d$  goes to 0. And  $R_v$  also goes to 0 and then  $R_a$  is equal to 1, so that means what we can clearly see that at lower values  $R_a$   $R_d$  is sensitive at higher values of frequency ratio  $R_a$  is sensitive and let resonating frequencies  $R_v$  is sensitive, so if we look at the relationship bit among these three things  $R_a$  divided by frequency ratio is equal to  $R_v$  that is again equal to  $r.R_d$ .

(Refer Slide Time: 11:22)

**Special Cases**  
**Case-1**  
@  $r = 0$       $\phi = 0^0$   
 $R_d = 1$

$$R_d = \frac{1}{\sqrt{(1-r^2)^2 + (2\xi r)^2}}$$

10

Now let us look at some special cases in this, what are these special cases, special case is if we discuss in detail that when  $r=0$  that is at rest condition, so at rest condition if you look at this  $R_d$  equation  $R_d = 1 / \sqrt{(1-r^2)^2 + (2\xi r)^2}$  now when  $r=0$  if you substitute in this one so what remains is so if all these values become 1 so  $R_d$  becomes 1, and this phase is 0 so that means what at rest condition or near rest condition so when the forcing frequency is applied like this.

So in the direction of force displacement will be there, so that is what is the meaning of in phase so  $\phi = 0$  means in phase and  $\phi = 90$  is in phase only suddenly if it shifts and goes to 180 that is out of phase.

(Refer Slide Time: 12:19)

**Special Cases**

**Case-1**

@  $r = 0$        $\phi = 0^0$

$R_d = 1 \Rightarrow \frac{u_0}{u_{st}}$

$u_0 = u_{st} = \frac{P_0}{k}$

$R_d = \frac{1}{\sqrt{(1-r^2)^2 + (2\zeta r)^2}}$

Stiffness Controlling system

- If frequency ratio  $r$  is much less than 1
  - Slowly varying force
  - $R_d$  slightly larger than 1
  - System becomes independent of damping

10

Now if we substitute this value what happens is  $r_d = 1$   $r_d$  means  $u_0 / u_{st}$  if it is = 1 there it gives us  $u_0 = u_{st}$  so that means what  $u_{st} u_0 u_s = p_0/k$  so what we are understanding from this is  $p_0$  is the externally applied force amplitude, amplitude of externally applied force then  $k$  is stiffness control in so that means what  $k$  is stiffness so when  $r = 0$  or nearly 0 vibration is control by stiffness so that means stiffness control is system it is.

So if frequency ratio  $r$  is much less than one it is slowly varying force  $r_d$  is slightly larger than one so that means what it can be 1, 1.0, 1.001 or 1.12 something like that the system becomes independent of damping here damping here damping as no role to play whatever damping maybe present in the system but deflection is control by stiffness so more stiff less displacement less stiff more displacement. So this is first special case where force is slowly varying.

(Refer Slide Time: 13:32)

**Special Cases**  
**Case-2**

$R_d \approx \frac{1}{r^2}$   $\phi = 180^\circ$

$u_0 = u_a \frac{1}{r^2} = \frac{P_0}{m\omega^2}$

$R_d = \frac{1}{\sqrt{(1-r^2)^2 + (2\zeta r)^2}}$

$\zeta = 2.0$

$\frac{P_0}{k} \frac{1}{\omega^2} = \frac{P_0}{k} \frac{1}{\omega^2}$

$= \frac{P_0}{k \omega^2} = \frac{P_0}{m \omega^2}$

Mass Controlling system

11

And the second special case is when force is rapidly varying so when force is rapidly varying means what high frequency forces are acting on the system when we look at the rd response curve so  $1 / \sqrt{(1- r^2)^2 + 2 \zeta r^2}$  so that means what r value is much much larger so if r value is much much larger this second will be significance so  $\sqrt{\quad}$  and square that becomes only  $1/r^2$  so this is approximately equal to  $1/ r^2$  if you put some numerical numbers and you check so you will get the similar value.

Maybe you can put say r = say 20 and check approximately that will be same you will get in this one and zeta any value zeta will become in sensitive there like  $1/ r^2$  rd =  $1/r^2$  and this shows that it is out of phase so when r value is more than one vibration amplitude vibration becomes out of phase when r value is less than one vibration amplitude is in phase it is something like when force is applied when this force is applied displacement in the same direction.

But when the r value is very large when force is applied displacement comes like this so it goes like this okay using this rd =  $1/r^2$  relationship as you can see so this is equal to  $u_0/ \omega^2$  so that means what  $u_0 = 1/r^2 \times \omega^2$ ,  $\omega^2 \times 1/r^2$  so that means  $1/r^2$  means  $P_0 / \omega^2 \times 1/r^2$  so  $\omega^2$  is  $t_0 / k$

and if you expand this one if you open this one what is going to happen is something like this  $p_0/k \times 1/t^2$  so that is equal to  $p_0/k \times \omega n^2 / \omega^2$ .

So you note by  $k \omega^2 \times \omega n^2$  means  $\sqrt{k/m}$ , will be left with  $p_0 / m\omega^2$  sorry this n is not there so  $p_0 / m \omega^2$  and if we look at this one this is controlled by mass so that means what, what system parameter is there is in this one mass is there so more mass less amplitude less mass more amplitude in the earlier case more stiffness less displacement less stiffness more displacement that is a.

(Refer Slide Time: 16:29)

**Special Cases**  
**Case-2**

$R_d = \frac{1}{\sqrt{(1-r^2)^2 + (2\zeta r)^2}}$

$@ r \gg 1 \quad R_d \approx \frac{1}{r^2} \quad \phi = 180^\circ$

$u_0 = u_{st} \frac{1}{r^2} = \frac{P_0}{m\omega^2}$

$\frac{P_0}{k} \frac{1}{r^2} = \frac{P_0}{k} \frac{1}{\omega^2} = \frac{P_0}{k \omega^2} = \frac{P_0}{m \omega^2}$

**Mass Controlling system**

- If frequency ratio  $r$  is much greater than 1
- $R_d$  tends to 0 and essentially unaffected by damping
- For large values of  $r$ , vibration is controlled by mass

11

Special case one this is a special case two so in this one what we can summaries is the frequency ratio is much greater than 1 that is rapidly varying force then already tents to 0 and it is it essentially unaffected by damping so higher value means it is very, very less value  $1/R^2$  for large values of  $R$  vibration is controlled by mass so mass controlled system so slowly varying force Stiffness control system rapidly varying force mass control system.

(Refer Slide Time: 17:00)

**Special Cases**  
**Case-3**

$$R_d = \frac{1}{\sqrt{(1-r^2)^2 + (2\xi r)^2}}$$

@  $r=1$   $R_d = \frac{1}{2\xi} = \frac{U_0}{\sqrt{U_0}} 90^\circ$

$$U_0 = \frac{P_0}{k} \frac{1}{2\xi}$$

Damping Controlling system

Now let's look at the third special case third special case is when  $r=1$  so that means what then forcing frequency is very near to the resonating frequency okay. so if you look at the this one and substitute  $R=1$  here so will be left with  $2\xi$  so  $R_d = 2\xi$  so that's nothing but  $U_0/USR$   $R_d =$  ratio of dynamic to static displacement. So and then  $\phi$  is  $90$  so faces is exactly  $90$  that is the switching of location so  $p_0/k$   $1/2\xi$  so here  $\xi$  is damping ratio that means we call it as vibration is controlled by damping.

(Refer Slide Time: 17:48)

**Special Cases**  
**Case-3**

$R_d = \frac{1}{\sqrt{(1-r^2)^2 + (2\zeta r)^2}}$

@  $r = 1$   $R_d = \frac{1}{2\zeta} = \frac{U_0}{\phi \sqrt{1-\zeta^2}} 90^\circ$

$U_a = \frac{P_a}{k} \frac{1}{2\zeta}$

**Damping Controlling system**

- If frequency ratio  $r$  is equal 1
- $R_d$  becomes very sensitive to damping
- For smaller damping values  $R_d$  can be several times larger than 1
- Implying that the dynamic deformation can be much larger than the static deformation

12

So if frequency ratio is =1 RD becomes very sensitive to damping and for small values of damping Rd can be several times larger than 1 implying that dynamic differ measure can be larger than static deformation at this range so as in summary we have studied like RD dynamic response factor for displacement dynamic response factor for velocity dynamic response factor for acceleration. And how these three things are related that way of studied in this class and then in dynamic amplification curve Rd.

So different places the sensitivity we have studied so when force is slowly varying okay that means R value is near one then deformation is controlled by stiffness and when force is rapidly varying then R value is very, very large so that is rapidly varying force. Deformation are controlled by mass and then when R is around resonating frequency around 1 that means forcing frequency and natural frequency are same nearly equal and then deformation is controlled by damping.

So K control system N control system and C control system so these three things three controls when they come into picture so that we have discussed in this class.
