**Part 1**  
**Concept of Force**  
**Representation of Vector**

In the last class we saw some introduction to matrix algebra or linear algebra is how to add 2 matrices, how to multiply 2 matrices and then we moved on to initial notations wherein we saw what a dummy index is, what a free index is and then we moved on to vector algebra or in we saw some basic vector operations like vector addition, scalar multiplication and then dot product, cross product and scalar triple products. And we understood the geometrical meaning. In particular we understood that vectors a dotted line segment for us is the geometric law object as a set of numbers. Now in this class we will see how we can transform a geometric law object into a set of numbers so that we can do algebra with it.

You need this because in today's world we are using computers or calculators to do the calculations which can work on only numbers, but cannot work on geometrical objects. So, we need to convert a geometrical object into a some format when you can do algebra with it that is in the some representation which has numbers using which we can do some calculations. It is similar to representing numbers using a basis 1 2, 0 to 0 or representing numbers using only 0 and 1 it is a binary format use a computer uses. So, there is an equivalence between these 2 representation of number system right. Similarly we will see today how you can represent the geometrical objects of a vector using some numbers.

(Refer Slide Time: 01:55)

So, basically in the last class we saw that this that line segment is what we called as a vector let us denote by  $\underline{a}$ . Now let us say that I am defining 3 other dotted line segments called  $\underline{e}_1$  which you would have denoted by  $\underline{i}$  vector or which you can denote equivalently by  $\underline{e}_x$  these are difference symbol that are used they represent this dotted line segment. And another dotted line segment  $\underline{e}_2$  which will call it as which you might be using the symbol  $\underline{j}$  in a previous courses or you can generated by  $\underline{e}_y$  which will use  $\underline{e}_2$  and  $\underline{e}_y$  are notation there will use frequently in this course. Another third dotted line segment which is  $\underline{e}_3$  which will denoted by  $\underline{k}$  or  $\underline{e}_z$ .

Now, this dotted line segment  $\underline{a}$  you want to represent using this  $\underline{e}_1$ ,  $\underline{e}_2$ ,  $\underline{e}_3$  as the 3 dotted line segments you want to use those 3 dotted line segments and represent  $\underline{a}$ . What does this mean? It is like representing numbers say ninety nine as nine into ten plus nine there is a representation of 99 right similarly you want to represent this  $\underline{a}$  using this 3 dotted line segment  $\underline{e}_1$   $\underline{e}_2$   $\underline{e}_3$ . So, when you are right  $\underline{a}$  has a 1  $\underline{e}_1$  plus a 2  $\underline{e}_2$  plus a 3  $\underline{e}_3$  or subsequently this can be written as  $a_i \underline{e}_i$ , this is a reason why I am using 1 2 3 as the index was the basis vectors rather than  $x y z$  are  $i j k$  for the basis vectors.

As we said in the last class  $\underline{i}$  is represented twice and dense it is called as a dummy index and dense it as we sound from 1 2 3 whose what I will one says from now on. Now how do I find this  $a_i$ ? I can find  $a_i$  my projecting  $\underline{a}$  onto the basis vectors  $\underline{e}_i$ , till they are underscore for me means the same thing I am not destination till day from underscore

sometimes I use till day sometimes I use underscore. So, this  $e_i$  is a basis vector. So,  $a_i$  is the projection of  $a$  onto  $e_i$  that is the meaning of  $a_i$  the component of the vector  $a$  in the direction of  $e_i$ . Now let us combining these 2 I can write  $a$  as a dotted with  $e_i$  times  $e_i$ .

This is a general representation of a vector using 3 as a dotted line segments. So, any vector you can represent using 3 dotted line segments. Why do need 3 dotted line segment because a spaces 3 dimensional, because space or to be 2 dimensional that maybe recommended 2 basis vectors which might be  $x$  and  $y$  or  $e_x$   $e_y$  or  $e_1$   $e_2$  and so on. So, you are representative vector as this.

Now how do I know that  $a_i$  is say dotted with  $e_i$ , that come from a definition of the dot product that you are interested in projecting  $a$  along the  $e_i$ th direction. So, that is how you know that it is a projection  $a_i$  is nothing, but a dotted with  $e_i$ . Now this 3 dotted line segment that I chose  $e_1$   $e_2$   $e_3$  was arbitrary right I came and do some 3 dotted line segment and chose it to represent in your dotted line segment which was say.

Now, say your friend comes about and says that he does not want to use this dotted line segments, but he wants to use something different you wants to use this which we called it as  $e_1^*$   $e_2^*$  and say  $e_3^*$   $e$  agrees with a direction and this is  $e_3^*$  that is as rotated the basis vector by an angle  $\theta$  the anticlockwise direction to get  $e_1^*$   $e_2^*$   $e_3^*$  about the  $z$  axis. So, basically now  $e$  once represent this vector  $a$  using the same vector  $a$  using the base vector  $e_1^*$   $e_2^*$   $e_3^*$  then what will  $a$ ,  $a$  in this red basis would be  $a_1^*$   $e_1^*$  plus  $a_2^*$   $e_2^*$  plus  $a_3^*$   $e_3^*$  or in short form  $a_i^* e_i^*$  or you can write this  $a$  has a dotted with  $a_i^* e_i^*$ .

Same thing where  $a_i^*$  is a dot similar to this I will have  $a_i^*$  to be given by a dotted with  $e_i^*$ . So, I have is to different representations. So, there is no sanity that the number  $a_1$ ,  $a_2$ ,  $a_3$  alone represent this vector that is what you are trying to understand here. The numbers if I write  $a$  as if I write  $a$  as  $a_1$   $a_2$   $a_3$  this column vector alone does not represent  $a$ , but  $d_1$  this column vector  $a_1^*$   $a_2^*$   $a_3^*$  represents the same vector  $a$ . So, there is not that only 1 set of numbers 1 2 3 represent a vector there will be n number of other 3 combinations will represent the same vector. What are those 3 combinations given a combination is what we are trying to find out now.

So, what is the relationship between, what is the relationship between  $a_i$  and  $a_i^*$  is the question we are trying to answer now. They represent the same vector  $a_i$  right, both a

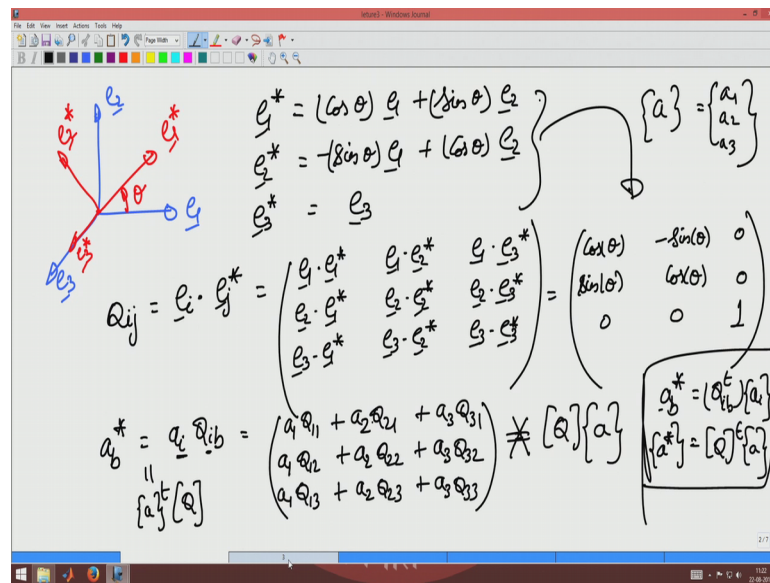

$i$  and  $a_i$  represent the same vector  $a$ . So, the magnitude of  $a$  has to be the same and direction related direction with respect to any other dotted line segment has to be the same. So, what does this mean? I go and substitute for from this equation I take this equation  $a = \sum e_i a_i$ , I rewrite this as  $a = \sum e_j a_j$  repeating twice. So, I can replace  $j$  with  $k$  or  $i$  or  $a$  or  $b$  or  $c$  or  $d$  it does not matter is since it is repeated twice again change the similar that I use the represent number that is what I have done.

Now, for  $a$  as substitute the fact that it can be written as this is  $a$ , I use this and substitute for  $a = \sum e_i a_i$  to get  $a = \sum e_i \sum e_j a_j$ . Now then I go back to this equation where I want to find  $a_j$  would be  $a = \sum e_j a_j$  which will be  $a_i$  or let me say this is  $b$  that will be  $a = \sum e_i \sum e_j a_j$  dotted with  $e_b$  star I could not I could not have use  $j$  here because that while is this summation convention they will appear thrice on the same (Refer Time: 10:47) or equal to same which is not allowed.

So, this is this now what do I know I know that  $e_i \cdot e_j = \delta_{ij}$  right from what we defined conical delta in the previous class it will be 0 if  $i$  is not equal to  $j$  and 1 if  $i$  equal to  $j$  what does this mean the basis are ortho normal, ortho normal basis. That is the magnitude of each of this basis vector is 1 and their mutually orthogonal  $e_1 \cdot e_2 = 0$   $e_2 \cdot e_3 = 0$   $e_3 \cdot e_1 = 0$ . So, they are mutually orthogonal and the magnitude of each of this vectors is 1 that is what this ortho normal basis mania.

Similarly, I have  $e_i \cdot e_j = \delta_{ij}$ . So, from that I get that this is  $a_i \delta_{ij} = a_j$  for this this become  $a_j$  and this I write it as  $a_j$ . It is easy to see that  $e_i \cdot e_j = \delta_{ij}$  because they are some they are not orthogonal.

(Refer Slide Time: 12:27)

So, let us write now for the transformation that we add that may redraw the figure, the axis  $e_1$   $e_2$   $e_3$  and I add the axis rotated by  $e_1^*$   $e_2^*$  and  $e_3^*$  or like this because anticlockwise rotation of  $\theta$ . So, now, what is  $e_1^*$  in terms of  $e_1$  and  $e_2$ ? Add to project  $e_1^*$  on to  $e_1$  that will be  $\cos \theta$   $e_1$  plus projecting this on to this is  $90$  minus  $\theta$ , so projecting this on to this it will be  $\sin \theta$   $e_2$ . Again  $e_1^*$   $e_2^*$   $e_3^*$  are of length unity and hence you can write this as this, similarly  $e_2^*$  would be minus  $\sin \theta$   $e_1$  plus  $\cos \theta$   $e_2$  and  $e_3^*$  will be same as  $e_3$ .

Now let us find this matrix  $Q_{ij}$  which was  $e_i$  dotted with  $e_j^*$ . Going back to the equation you can see that  $Q_{ij}$  is  $e_i$  dot  $e_j^*$  right. So, you want to write what this matrix  $Q_{ij}$  is. So, it will be  $e_1$  dotted with  $e_1^*$   $e_1$  dotted with  $e_2^*$   $e_1$  dotted with  $e_3^*$  here it is going to be  $e_2$  dotted with  $e_1^*$   $e_2$  dotted with  $e_2^*$   $e_2$  dotted with  $e_3^*$   $e_3$  dotted with  $e_1^*$   $e_3$  dotted with  $e_2^*$   $e_3$  dotted with  $e_3^*$  and for this  $e_1$   $e_2$   $e_3^*$  what you get is you get it as  $\cos \theta$   $\sin \theta$   $0$ ,  $0$   $0$   $1$ . That is what you get the  $Q_{ij}$  matrix to be.

So, now going back to previous equation  $a_b^*$  is,  $a_b^*$  is given by this expression now, I can simplify this expression for the if  $j$  and  $b$  are not same they are going to be  $0$  right. So, I can replace  $j$  with  $b$  or  $b$  with  $j$ . So, let me replace  $j$  with  $b$ . So, this will be  $a_i Q_{ib}$ ,  $Q_{ib}$ . Now, you can see that there is a problem here if I define it like this what I will do is; let me come to the next page. What I add the final equation I add was this  $a_b^*$

equal to a  $i$   $Q$   $ib$  right, I add a  $b$  star is a  $i$   $Q$   $ib$  what does this mean I add to some the this index  $i$  and  $b$  is  $a$ ; a  $i$  is a dummy index and  $b$  is a free index. So, this means I have a  $1$   $Q$   $11$  plus a  $2$   $Q$   $21$  plus a  $3$   $Q$   $31$  a  $1$   $Q$   $12$  plus a  $2$   $Q$   $22$  plus a  $3$   $Q$   $32$  a  $1$   $Q$   $13$  plus a  $2$   $Q$   $23$  plus a  $3$   $Q$   $33$ . This is a meaning of this equation right.

Now this is not equivalent to multiplying this vector  $Q$  with this  $a$ . This means this is not equal to this, but this means this is equal to a transpose multiplied by  $Q$ . If I think of a  $a$  I think of a vector as being a  $1$   $a$   $2$   $a$   $3$ . This is the operational gives me this initial notational, but I want to write like this. So, what do I do? I define I can write this as now a  $b$  star can be written as  $Q$  transpose  $ib$  into a  $i$ . So, in other words a star is the  $Q$  transpose a where  $Q$  is this matrix. So, we can see if I transpose this I will get the right addition of the terms here. So, this is the representation, final representation that we got for a star.

(Refer Slide Time: 18:32)

$$\begin{Bmatrix} a_1^* \\ a_2^* \\ a_3^* \end{Bmatrix} = \begin{pmatrix} \cos(\theta) & \sin(\theta) & 0 \\ -\sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{Bmatrix} a_1 \\ a_2 \\ a_3 \end{Bmatrix} = \begin{Bmatrix} \cos(\theta)a_1 + \sin(\theta)a_2 \\ -\sin(\theta)a_1 + \cos(\theta)a_2 \\ a_3 \end{Bmatrix} = \begin{Bmatrix} a_1^* \\ a_2^* \\ a_3^* \end{Bmatrix}$$

Is there any restriction on the matrix  $[Q]$ ?

$$\{a^*\} = [Q]^t \{a\}; \quad a_b^* = Q_{ib} a_i$$

$$\|a\| = (a \cdot a)^{1/2} = (a_i e_i \cdot a_j e_j)^{1/2} = (a_i a_j \delta_{ij})^{1/2} = (a_i^2)^{1/2} = (a_1^2 + a_2^2 + a_3^2)^{1/2}$$

$$\|a^*\} = (a^* \cdot a^*)^{1/2} = (a_i^* e_i \cdot a_j^* e_j)^{1/2} = (a_i^* a_j^* \delta_{ij})^{1/2} = (a_j^2)^{1/2} = \|a\|$$

$$a_j^* = \{a^*\}^t \{e_j^*\} = \{a_1^* \ a_2^* \ a_3^*\} \begin{Bmatrix} a_1^* \\ a_2^* \\ a_3^* \end{Bmatrix}$$

$$= [Q]^t \{a\} \{e_j^*\} = \{a\}^t [Q]^t \{e_j^*\}$$

$$\begin{Bmatrix} [A] [B]^t \\ = [B]^t [A]^t \end{Bmatrix}$$

Now let us see what happens for in for the case that we are considered. So, a star would be  $\cos$  theta minus  $\sin$  theta  $\sin$  theta  $\cos$  theta  $0$   $0$   $0$   $1$  into a  $1$   $a$   $2$   $a$   $3$ . So, this will be  $\cos$  theta into a  $1$  plus  $\sin$  theta into a  $2$  minus  $\sin$  theta a  $1$  plus  $\cos$  theta a  $2$  and a  $3$ . This is a  $1$  star a  $2$  star a  $3$  star. So, for a planar rotation theta can be any value. So, all this set of values that you get by multiplying  $\cos$  theta and  $\sin$  theta with a  $1$  and a  $2$  or admissible components of the vector all this what you get a  $1$  star a  $2$  star a  $3$  star or also admissible components of that vector  $a$ , and represent the same vector.

Now let us find is there any restriction on, is there any restriction on the matrix  $Q$ . Let us answer this question. So, basically now we add that a star is  $Q$  transpose a right this is the equation we got in matrix multiplication term this is what it is. In component terms you add a star  $b$  as  $Q_{ib} a_i$ ,  $Q_{ib} a_i$ .

So, basically now what do we know if a star also represent the same vector  $a$ , if a star also represents the same vector  $a$  phase are also represents the same vector  $a$  then the mounted of this vector has to be the same. If a star also represents  $a$ , the mounted of  $a$  should remain same whether  $I$  represented using  $a_1 a_2 a_3$  or  $a_1$  star  $a_2$  star  $a_3$  star. So, I am interested in finding what you mounted is interested in finding the mounted of  $a$  that we saw in the last classes  $a$  dotted with  $a$  over a square root.

So, this will be  $a_i e_i$  dotted with  $a_j e_j$  square root, I use the representation of the vector as  $a_i e_i + a_j e_j$ , I can be represent with  $j$  because  $i$  and  $j$  are dummy indexes. So, this will be  $a_i a_j \delta_{ij}$  power half again this conical  $\delta_{ij}$  is not equal to  $j$  this is going to be equal to 0. So, what I can do is I can replace  $i$  with  $j$  this will become  $a_i$  squared power half. This is  $a_i$  square is  $I$  represented twice so this will be nothing, but  $a_1$  square plus  $a_2$  square plus  $a_3$  square power half that is why you can cancel this 2 with this off it is some it means I have to some  $I$  from 1 2 3.

Now, let us do the same thing for this primed stared corner system  $a_i$  star  $e_i$  star dotted with  $a_j$  star  $e_j$  star power half this also I will get it as  $a_j$  star squared power half and I know  $a_j$  star squared is, now, how do I define  $a_j$  star squared this can be written as a star transposed with a star right a star  $a_i$ ; form me vector is a column vector say a star transpose will give me  $a_1$  star,  $a_2$  star,  $a_3$  star and this is  $a_1$  star,  $a_2$  star and  $a_3$  star. So, this gives me  $a_j$  square.

Now substituting this, substituting this for a star what do I get is, I get it as  $Q$  transpose a the whole transpose  $Q$  transpose a vector. So, you know that  $A$  matrix  $B$  matrix multiplied and transposed is  $B$  transpose  $A$  transpose. So, this will become a transpose  $Q$   $q$  transpose  $a$ . If there is a  $j$  star square.

(Refer Slide Time: 24:51)

The image shows a whiteboard with the following handwritten content:

$$\|a\| = (a^T a)^{1/2} = [a^T]^{1/2} [a]^{1/2} = (a^T)^{1/2} [Q][Q]^T [a]^{1/2}$$

$$[a^T] [1] [a] = [a^T] \left( [1] - [Q][Q]^T \right) [a] = 0 \quad \leftarrow \text{To hold for any } [a]$$

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \quad [Q][Q]^T = [1]$$

$$[A][A]^T = [1] \quad \leftarrow \text{inverse of } [A]$$

$$[Q]^{-1} = [Q]^T \quad \leftarrow \text{Orthogonal matrix}$$

$[Q]$  has to be an orthogonal matrix.

So, you have norm of a given by a i square, a i squared power half that is r nothing, but a transpose a this is nothing but a j squared power half which is nothing, but from what we found here this a j star squared we are using that expression in a to get it as a transpose Q, Q transpose a is what we got. Now from this two, we find that I can write it as a transpose into this as we equal. So, equating from those 2 I will get it as identity matrix we will see what this is in a short while Q, Q transpose times a has to be equal to 0.

Now, this identity matrix means the diagonal terms are alone 1 0 0, 0 1 0, 0 0 1. So, you can see I have done nothing if I multiply this with a i will get back a. So, what I have done is I have written this as a transpose identity matrix times a and essentially I have nothing in a just that I have introduce one more matrix here for simplification. This has to hold to hold for any a i require this as hold for any a, which implies that Q Q transpose has to be an identity matrix. What does this mean? We know that if I have a, a and a inverse then this will result in a identity matrix right this is called as inverse of a.

That will be an identity matrix which means here for Q, Q inverse is equal to the transpose of Q that is what is means inverse of the matrix is a transpose of the matrix this matrix is are called as orthogonal matrix such matrix are called as orthogonal matrix for inverse is transpose. So, there is a restriction on, this is the restriction on Q. So, Q has to be and orthogonal matrix. For it to be able to map different components of the same

dotted line segment that is a restriction. So, let us go back here let us check whether this satisfy this Q satisfies this property.

Let us check whether this Q satisfies this property that it is an orthogonal matrix.

(Refer Slide Time: 28:33)

The image shows a whiteboard with the following handwritten content:

$$[Q] = \begin{bmatrix} \cos(\theta) & -\sin(\theta) & 0 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{bmatrix}; \quad [Q][Q]^t = \begin{bmatrix} \cos^2\theta + \sin^2\theta & 0 & 0 \\ 0 & \cos^2\theta + \sin^2\theta & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$[Q]^t = \begin{bmatrix} \cos(\theta) & \sin(\theta) & 0 \\ -\sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{bmatrix} = [I]$$

$$\underline{a} = a_i \underline{e}_i = a_i^* \underline{e}_i^* ; \quad \{a^*\} = [Q]^t \{a\}; \quad Q_{ij} = \underline{e}_i \cdot \underline{e}_j^*$$

For our example Q is cos theta minus sin theta sin theta cos theta 0 0 0 0 1; I am interested in finding Q Q transpose what will it be. So, you can see that it is going to be if Q is that Q transpose would be cos theta minus sin theta sin theta cos theta 0 0 0 0 1 and if I multiply this is going to be cos square theta plus sin squared theta 0 0 0 again cos square theta plus sin square theta 0 0 0 1 from trigonometry you know that this is also equal to 1 and hence it is an identity matrix.

So that is why it was a, that is how it forms a transformation matrix. So, what you understood till now is I can the present a vector a as a i e i where a i are a i star e i star or a star would be related to a as Q transpose a where Q ij is e i dotted with e j star.
