Stresses and deflection in beams not loaded about principal axis
Lecture – 76
Load not about principal axis

Welcome to lecture 27 of mechanics of materials, the last lecture we saw how to derive general equation for bi-directional bending that is, when the load is not applied along one of the principal axis the cross section. We saw how to get the deflections and stresses in particular, we saw that the expression for stress is given by this expression in here and the expression for the corresponding deflection along the y and z direction is given in here.

(Refer Slide Time: 00:38)

BIDIRECTIONAL BENDING - EXAMPLE PROBLEM

$$E \frac{d^2 \Delta_y}{dx^2} = \frac{I_{yy} M_z + I_{yz} M_y}{I_{zz} I_{yy} - I_{yz}^2} \quad \alpha \quad E \frac{d^2 \Delta_z}{dx^2} = - \frac{I_{yz} M_z + I_{zz} M_y}{I_{yy} I_{zz} - I_{yz}^2}$$

$$\sigma_{xx} = -(y - y_0) \left[\frac{I_{yy} M_z + I_{yz} M_y}{I_{yy} I_{zz} - I_{yz}^2} \right] + (z - z_0) \left[\frac{I_{yz} M_z + I_{zz} M_y}{I_{yy} I_{zz} - I_{yz}^2} \right]$$

ORIENTATION OF NEUTRAL AXIS:

$$\frac{z - z_0}{y - y_0} = \tan \beta = \frac{I_{yy} M_z + I_{yz} M_y}{I_{yz} M_z + I_{zz} M_y}$$

So, we also saw that now, the neutral axis will not be aligned along with the axis of the problem that we have chosen, but it will be inclined to the axis of the cross section that we have chosen and that expression is given by, the expression given here tan beta equal to I yy into M z plus I yz into M y divided by I yz into M z plus I zz into M y. In today's lecture will apply these concepts to solve 2 problems, one is an equal angle loaded about one of it is legs like this and an equal angle loaded about it is principal axis one of the principal axis like that.

(Refer Slide Time: 01:34)

$y_{CG} = z_{CG} = 31.2 \text{ mm}$; $I_{yy} = I_{zz} = 2.4 \times 10^6 \text{ mm}^4$; $I_{yz} = 1.4 \times 10^6 \text{ mm}^4$
 Orientation of the principal axis, $\phi = \frac{1}{2} \tan^{-1} \left(\frac{2I_{yz}}{I_{zz} - I_{yy}} \right) = 45^\circ$
 $M_x = \begin{cases} \frac{P}{2}x, & 0 \leq x \leq L/2 \\ \frac{P}{2}(L-x), & L/2 \leq x \leq L \end{cases}$ $M_y = 0$
 $E \frac{d^2 y}{dx^2} = \frac{I_{yy}}{I_{yy}I_{zz} - I_{yz}^2} M_x = k_1 M_x$; $k_1 = 0.63$
 $E \frac{d^2 z}{dx^2} = \frac{-I_{yz}}{I_{yy}I_{zz} - I_{yz}^2} M_x = -k_2 M_x$; $k_2 = 0.37$

So, this what we are going to do in today's lecture. In particular we are interested in solving the problem, where in you have a simply supported beam subject to a point load in the middle, and this point load is acting on one of the legs in the first problem of the equal angle section. The dimensions of the angular given here, each of the angle is like this 100 mm in length and 10 mm in thickness. In lecture 25 we saw how to compute the moment of inertia on the center of this cross section. So, I am not going to repeat how I am going to compute the center and the moment of inertia of this cross section, but give the end the cells.

So, for this cross section the y CG is since is an equal angle cross section, you know that the centroid of y centroid and z centroid would be same, and that is equal to 31.2 mm that is this distance is y CG and this distance is it z CG what are the mark 31.2 mm.

Now, similarly for this cross section for the oriented axis I yy to be equal to I zz, again because of a sequel angle and that will be equal to 2.4 into 10 power 6-millimeter power 4 and then I yz is going to be 1.4 into 10 power 6-millimeter power 4, for this oriented orientation of the coordinate system y NC directions. So, basically these are the section properties of the cross section.

Now, a first thing we want to find this, we want to find what is the orientation of the principal axis? So, to find the orientation of the principal axis, we saw and lecture 25 again this is given by 1 half tan inverse of 2 times I yz divided by I zz minus I yy since I

I_{zz} and I_{yy} are same this happens to be 45 degrees, because tan inverse of infinity is 90 degrees and this happens to be 45 degrees. So, the principal axis is oriented like this at the rotation of 45 degrees to this, this will be your u and this will be your v for this angle is 45 degrees the ϕ . So, that is the orientation of principal axis.

Now, for this loading for this orientation of the coordinate system, you know that the moment that is produced is a M_z moment and you can find what is the support reaction, the support reactions are going to be, the simply supported beam the support reactions are going to be $P/2$, I am not going to go into the direction of this, the load is acting and the center. So, you take a moment about one of the edges one of the supports say, at A you get that from the moment balance will get the reaction at B to be $P/2$ and from the vertical first equilibrium, then the reaction at a has to be $P/2$ the same thing can be inferred from the symmetry of the problem.

So, there is a free body diagram of this beam and hence, the variation of M_z moment M_z variation of M_z moment with x is given by, $P/2$ into x for $0 < x < L/2$ and $P/2$ into $L - x$ for $L/2 < x < L$, here x is measured from the end A x is measured from here, this is x any section here would be x . So, any section on this segment section here, will have a distance from the same d as $L - x$.

So, basically now for a section greater than $L/2$ it will be $P/2$ into $L - x$ will be the moment, that comes in at that section point, by now you should be familiar with writing this equations you have done that thrice in this course. So, you have to be conversant in writing these equations. So, M_z is this now going back to our expression for the deflections, you will find that M_y is 0 for this M_z is this and M_y is 0, because a load is acting along the y direction. So, M_y is 0 for this case you will find that E times $d^2 \Delta y / dx^2$ is given by $I_{yy} / I_{zz} - I_{yz}^2$ into M_z M_y is 0.

So, I have used this fact and put the bending moment equations, into this equation in here I put the bending moment M_z and M_y into the equation in here, and hence got that this I will write it has k_1 times M_z , where k_1 for our cross section has 0.63. Similarly, E times $d^2 \Delta z / dx^2$ from the equation above will be, minus $I_{yz} / I_{yy} I_{zz} - I_{yz}^2$ times M_z this will write it as k_2 times M_z k_2 is 0.37 for our cross section.

(Refer Slide Time: 09:03)

$$E \frac{d\Delta y}{dx} = \begin{cases} \frac{k_1 P x^2}{4} + C_1, & 0 \leq x \leq L/2 \\ -\frac{k_1 P (L-x)^2}{4} + C_2, & L/2 \leq x \leq L \end{cases}$$

$$E \Delta y = \begin{cases} \frac{k_1 P x^3}{12} + C_1 x + C_3, & 0 \leq x \leq L/2 \\ -\frac{k_1 P (L-x)^3}{12} + C_2 (L-x) + C_4, & L/2 \leq x \leq L \end{cases}$$

$$\Delta y(x=0) = \Delta y(x=L) = 0$$

$$\Delta y(x=0) = 0 \Rightarrow C_3 = 0 \quad \Delta y(x=L) = 0 \Rightarrow C_4 = 0$$

$$\Delta y(x=L/2^-) = \Delta y(x=L/2^+) \Rightarrow \frac{k_1 P L^3}{12 \cdot 8} + \frac{C_1 L}{2} = \frac{k_1 P L^3}{12 \cdot 8} - \frac{C_2 L}{2} \Rightarrow C_1 = -C_2$$

$$E \frac{d\Delta z}{dx} = \begin{cases} -\frac{k_2 P x^2}{4} + D_1, & 0 \leq x \leq L/2 \\ \frac{k_2 P (L-x)^2}{4} + D_2, & L/2 \leq x \leq L \end{cases}$$

$$E \Delta z = \begin{cases} -\frac{k_2 P x^3}{12} + D_1 x + D_3, & 0 \leq x \leq L/2 \\ -\frac{k_2 P (L-x)^3}{12} - D_2 (L-x) + D_4, & L/2 \leq x \leq L \end{cases}$$

$$\Delta z(x=0) = \Delta z(x=L) = 0$$

$$\Delta z(x=0) = 0 \Rightarrow D_3 = 0 \quad \Delta z(x=L) = 0 \Rightarrow D_4 = 0$$

$$\Delta z(x=L/2^-) = \Delta z(x=L/2^+) \Rightarrow -\frac{k_2 P L^3}{12 \cdot 8} + \frac{D_1 L}{2} = \frac{k_2 P L^3}{12 \cdot 8} - \frac{D_2 L}{2} \Rightarrow D_1 = -D_2$$

Now, proceeding further we got d square delta y and d square delta z dx square. So, we want to find the deflection and the stresses. So, the deflection is given by, to get the deflection d delta y, by dx is given by I substitute for M z into this equation. So, that will be P x square by 4 plus C 1 for 0 less than x less than L by 2 P L minus x square by 4 minus plus C 2 for 1 by 2 less than x less than L. Similarly, E d delta z by dx would be that should be a negative sign there minus k 2 M z, because it is a negative sign in there will be minus k 2 P x square by 4 plus D 1 for 0 less than x less than L by 2 minus k 2 P L minus x whole square by 4 negative sign for the differentiation makes is positive plus D 2 for 0 less than for 1 by 2 less than x less than L.

Now, integrating this once more, I get E times delta y to be k 1 P x cube by 12 plus C one x plus C 3 0 less than x less than L by 2 minus k 1 P L minus x cube by 12 and negative sign there coming in, because of the integration. So, that become positive I write C 2 x as minus C 2 the L minus x plus C 4 for convenience that, you will see later shortly now this is same as C 2 x, right? I have added C 2 L. So, C 4 would be C 4 minus C 2 L will adjust itself that is a constant.

Similarly, E times delta z is given by minus k 2 P x cubed by 12 plus d 1 x plus d 3, for 0 less than x less than L by 2 minus k 2 P to L minus x cube by 12 plus, I do the same trick here minus D 2 into L minus x plus D 4 for L by 2 less than x less than L. Next, I have to find the constant C 1 to C 4 and D 1 to D 4 for which I apply the boundary conditions, I

have simply support boundary condition means, delta y at x equal to 0 is equal to delta y at x equal to L, that has to be equal to 0 same thing in z direction I do not allow displacement in y or z. So, delta z at x equal to 0 and x equal to L has to be 0.

Here I am assuming it is simply supporting both y and z direction, but it is not always necessary, it can happen that it can be simply supported in y and fixed in z or vice versa are fixed in both. So, that depends upon the problem at an so, this is 0. So, these conditions will imply that delta y at x equal to 0 equal to 0 implies C 3 is 0 and delta y at x equal to L equal to 0 would imply C 4 is 0, similarly here delta z at x equal to 0 equal to 0 implies D 3 is 0 and delta z at x equal to L equal to 0 implies D 4 is equal to 0.

So, now we have to find constant C 1 and C 2, that comes from the continuity condition, the first continuity condition that will n forces delta y at x equal to L by 2 minus should be equal to delta y at x equal to L by 2 plus. So, what does this mean? This means k 1 P L cube by 12 into 8 plus C 1 into L by 2 C 3 0, must be equal to k 1 into P L cube by 12 into 8 minus C 2 into L by 2 this implies C 1 is equal to minus C 2.

Similarly, here delta z at x equal to L by 2 minus must be equal to delta z at x equal to L by 2 plus this is the continuity condition a del by 2, this will imply minus k 2 into P L cube by 12 into 8 plus D 1 into L by 2 must be equal to minus k 2 into P into L cube by 12 into 8 minus D 2 1 by 2 this again implies D 1 must be equal to minus D 2.

(Refer Slide Time: 15:32)

The image shows handwritten mathematical derivations for beam deflection and slope continuity conditions. The derivations are split into two columns.

Left Column (Deflection and Slope):

- Continuity of slope at $x = L/2$: $\frac{dD_1}{dx} \Big|_{x=L/2^-} = \frac{dD_2}{dx} \Big|_{x=L/2^+}$
- Equation: $\Rightarrow \frac{k_1 P L^2}{16} + C_1 = -\frac{k_1 P L^2}{16} + C_2$
- Equation: $\Rightarrow 2C_1 = -\frac{k_1 P L^2}{8}$
- Equation: $C_1 = -\frac{k_1 P L^2}{16}$
- Deflection function for $0 \leq x \leq L/2$: $F D_1 = \frac{k_1 P L^3}{48} \left[4 \left(\frac{x}{L} \right)^3 - 3 \left(\frac{x}{L} \right) \right]$
- Deflection function for $L/2 \leq x \leq L$: $F D_2 = \frac{k_1 P L^3}{48} \left[4 \left(1 - \frac{x}{L} \right)^3 - 3 \left(1 - \frac{x}{L} \right) \right]$
- Deflection at $x = L/2$: $F D_1(x=L/2) = -\frac{k_1 P L^3}{48}$

Right Column (Slope and Deflection):

- Continuity of slope at $x = L/2$: $\frac{dD_1}{dx} \Big|_{x=L/2^-} = \frac{dD_2}{dx} \Big|_{x=L/2^+}$
- Equation: $-\frac{k_2 P L^2}{16} + D_1 = \frac{k_2 P L^2}{16} + D_2$ where $D_1 = -D_2$
- Equation: $\Rightarrow D_1 = \frac{k_2 P L^2}{16}$
- Deflection function for $0 \leq x \leq L/2$: $F D_2 = \frac{-k_2 P L^3}{48} \left[4 \left(\frac{x}{L} \right)^3 - 3 \left(\frac{x}{L} \right) \right]$
- Deflection function for $L/2 \leq x \leq L$: $F D_2 = \frac{-k_2 P L^3}{48} \left[4 \left(1 - \frac{x}{L} \right)^3 - 3 \left(1 - \frac{x}{L} \right) \right]$
- Deflection at $x = L/2$: $F D_2(x=L/2) = \frac{k_2 P L^3}{48}$

Now, moving forward we want to apply continuity condition on $\frac{d\delta y}{dx}$. So, continuity condition second continuity condition that will be using is, $\frac{d\delta y}{dx}$ at x equal to $L/2$ minus, must be equal to $\frac{d\delta y}{dx}$ at x equal to $L/2$ plus. So, this condition will tell us that, from the equation here it will give us this implies k_1 into PL^2 square by 16 plus, C_1 must be equal to minus $k_1 PL^2$ square by 16 plus C_2 , already you have C_1 equal to minus C_2 . So, this would imply that this with this implies, $2C_1$ is minus $k_1 PL^2$ square by 16 into 2 or C_1 is minus $k_1 PL^2$ square by 60.

Similarly, applying the condition here, $\frac{d\delta z}{dy}$ $\frac{d\delta z}{dx}$ at x equal to $L/2$ minus, must be equal to $\frac{d\delta z}{dx}$ at x equal to $L/2$ plus, you will get minus $k_2 PL^2$ square by 16 plus D_1 must be equal to $k_2 PL^2$ square by 16 plus D_2 , here the sign differs because there is a negative sign in here you can see that this as differing sign from, what you add here hence the sign will differ.

So, this implies along with the condition that, D_1 the condition D_1 is equal to minus D_2 from the continuity of the displacement from, where you got that condition D_1 equal to minus D_2 here you got the condition D_1 equal to minus D_2 these 2 conditions together will tell you that D_1 is $k_2 PL^2$ square by 16.

Now, substituting all these values of constants into the deflection equation, you have E times δy to be given by $k_1 PL^3$ cube by 48 into $4x$ by L whole cube minus $3x$ by L , in the region $0 < x < L/2$ and I have $k_1 PL^3$ cube by 48, 4 into 1 minus x by L the whole cube minus 3 into 1 minus x by L in the region $L/2 < x < L$.

Similarly, E times δz is given by minus $k_2 PL^3$ cube by 48, 4 into x by L the whole cube minus 3 into x by L in the region $0 < x < L/2$ and minus $k_2 PL^3$ cube by 48 into 4 into x by L whole cube minus 3 into 1 minus x by L in the region $L/2 < x < L$.

Next, we are interested in finding what is $E\delta y$ at x equal to $L/2$ this will find is minus $k_1 P$. So, you will find this minus $k_1 PL^3$ cube by 48 and similarly here, you will find that E of δz at x equal to $L/2$ is $k_2 PL^3$ cube by 48 because, it is $1/2$ minus $3/2$ $1/2$ minus $3/2$ is minus 1 . So, this one with the negative sign becomes positive, but δz and it is negative for δy , because there is no negative sign in front of δy .

So, what does this mean, let us interpret this result with respect to the cross section, let us go back to the cross section, what deflection we got was, negative displacement in y and positive displacement in z. Which means the CG from here, will move to a point from the CG from here moves to a point somewhere here, where in this displacement is delta y absolute value of delta y and this displacement is absolute value of delta z that is the displacement.

So, what that says it moves down and it moves in this a direction, in the is a direction it moves down and out of plane out of the board white board. So, that is what it happen so now, this is one way of solving this problem, was another way of solving this problem and I can resolve these loads into the principal axis and I can do repeat the same thing, then what I will get this I will get the deflection along u and v directions..

I have to then dissolve the deflection along u and v directions. So, y and z direction, now what we are going to do is. So, I was going to resolve these forces along the principal directions. So, this P when this all along y u and v would be undersold along u and v it would be along v, this is going to be P by root 2, because it is 45-degree rotation that is what we saw for the principal axis from the given axis.

(Refer Slide Time: 22:26)

The image shows handwritten engineering notes on a whiteboard. On the left, there is a diagram of a rectangular cross-section with dimensions 100 mm by 100 mm. The centroidal axes are labeled y and z. A force P is applied at the corner. The principal axes u and v are shown at a 45-degree angle to the y and z axes. In the center, a beam of length L is shown with a load P at the midpoint. The beam is divided into two segments of length L/2. On the right, there is a free-body diagram of the right half of the beam, showing the load P/2 and the reaction P/2 at the midpoint. Below the diagrams, the following equations are written:

$$M_u = \begin{cases} \frac{P}{\sqrt{2}} x, & 0 \leq x \leq \frac{L}{2} \\ -\frac{P}{\sqrt{2}} (L-x), & \frac{L}{2} \leq x \leq L \end{cases}$$

$$M_v = \begin{cases} \frac{P}{\sqrt{2}} x, & 0 \leq x \leq \frac{L}{2} \\ \frac{P}{\sqrt{2}} (L-x), & \frac{L}{2} \leq x \leq L \end{cases}$$

$$\frac{E d^2 u}{dx^2} = \frac{M_v}{I_{vv}} ; \frac{E d^2 v}{dx^2} = \frac{M_u}{I_{uu}}$$

$$u = \frac{(D_y + D_z)}{\sqrt{2}} \quad \alpha \quad v = \frac{(-D_y + D_z)}{\sqrt{2}}$$

$$I_{uu} = \frac{I_{yy} + I_{zz}}{2} - I_{yz} \sin(90^\circ) = 1 \times 10^6 \text{ mm}^4$$

$$I_{vv} = \frac{I_{yy} + I_{zz}}{2} + I_{yz} \sin(90^\circ) = 3.8 \times 10^6 \text{ mm}^4$$

So, this will be P by root 2 and along the u is going to be P by root 2. So, we will have moments Mu and Mv Mu is given by P by root 2 into x for 0 less than x less than L by 2 and it will be given by, P by root 2 into L minus x for 0 less then, for x L by 2 less than x

less than L . Similarly, M_v moment given by P by $\sqrt{2}$ into x again, 0 less than x less than L by 2 minus P by $\sqrt{2}$ into L minus x for L by 2 less than x less than L .

Now, let us see how I got the M_u moment, M_u moment would be the load along u direction, load along v direction multiplied by the lever arm along the x direction, that will give me M_u moment. So, I have a load I have this angle cross section, in which the load is acting like this. So, this load is going to produce a M_u moment like this, the lower arm is along x that is a load acting like this. So, there will be a moment M_u produce, because of that load and that will be a negative moment and M_v moment is, the moment produced you to the load acting along u due to a lever arm along x direction, that will be the M_v moment that will be given by this expression in here.

So, that is the M_v moment there, now you know that I_{uv} is 0 since there is a principal axis, and hence E times d square ΔE square Δu by dx square, would be given by M_v divided by I_{vv} . Now, we have to find I_{uu} and I_{vv} . We will do that shortly and similarly E times d square Δv by dx square is given by M_u divided by I_{uu} M_u .

Now, I know that I can use more circle equations to transform my to find I_{uu} and I_{vv} I_{zz} and I_{yy} was same for this cross section. So, the expression for I_{uu} would become, I_{yy} plus I_{zz} by 2 minus I_{yz} into $\sin 2\phi$, which is $\sin 2$ times 45 degrees. So, it will be 2 times 90 degrees that is 1 so, this is I_{yy} and I_{zz} are same. So, I did not have a cast to feed term. So now, this boils down to 1 into 10 power 6 millimeter power 4 . Similarly, I_{vv} is given by I_{yy} plus I_{zz} by 2 plus I_{yz} into $\sin 90$ degrees. So, this will be 3.8 into 10 power 6 -millimeter power 4 .

Now, I have to repeat the steps that, I did for integrating the moments, similar to what I did in the previous case and find Δu and Δv , and you can show them the Δu would be given by Δu would be given by Δy that, we found in the previous expression as Δz by $\sqrt{2}$ and Δv would be given by minus Δy plus Δz by $\sqrt{2}$.

(Refer Slide Time: 27:51)

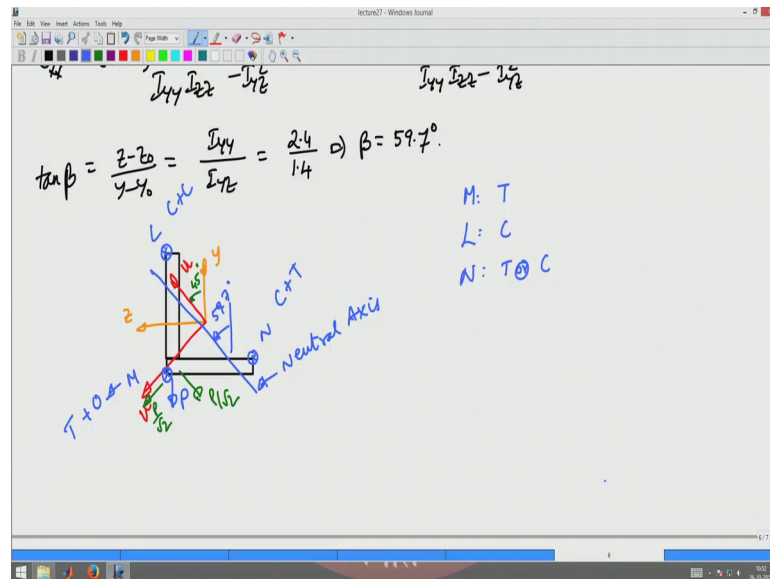

The screenshot shows a Windows Journal window with the following handwritten equations:

$$\sigma_{xx} = -(y - y_0) \frac{I_{yy}}{I_{yy}I_{zz} - I_{yz}^2} M_z + (z - z_0) \frac{I_{yz}}{I_{yy}I_{zz} - I_{yz}^2} M_z$$
$$\tan \beta = \frac{z - z_0}{y - y_0} = \frac{I_{yy}}{I_{yz}} = \frac{2.4}{1.4} \Rightarrow \beta = 59.7^\circ$$

Now, I leave this as an exercise for you to work it out and show. Now, moving on to the stress expression the stress σ_{xx} , now would be given by from the equation that we had before from this expression we will get this stress to be given by, y minus y naught into I_{yy} divided by $I_{yy}I_{zz}$ minus I_{yz} squared into M_z the negative sign in here, plus z minus z naught into I_{yz} divided by $I_{yy}I_{zz}$ minus I_{yz} squared M_z , we got the expression for M_z .

So, you know how the actual sets will vary along the axis of the beam and there is a variation along the cross section of the beam, in the cross section of the beam off interest is the neutral axis, that is the axis about which σ_{xx} is 0. So, you will find that the orientation of the neutral axis $\tan \beta$, is given by z minus z naught by y minus y naught. Which is nothing but I_{yy} divided by I_{yz} and this is 2.4 divided by 1.4, this would imply that β if you do the inverse of \tan it will be 59.7 degrees.

(Refer Slide Time: 29:33)

So, now if you look at the angle section the principle axis is oriented at 45 degrees this is 45 degrees but the neutral axis is oriented at 59.7 degrees that is the neutral axis is oriented in some line like that this is the neutral axis and its orientation from the vertical is 59.7 degrees. So now, what happens below the neutral axis, you are operating low like this and which points will be in tension and compression is a next in the we want to see. So, it is convenient to see that, when you resolve the forces into the principal axis orientations.

So, basically when I apply a lower like this, we are interested in finding what are the nature of stresses at points P at points L M and the N? To find the nature of stress at M, when I resolve a load along the principal axis direction, you find that the P by root 2 acting along v will produce compression at M, will produce tension at M and the load acting along the u direction, P by root 2 load acting along u direction that be the neutral axis. So, it low on produce any tension at M so, at M would be T plus 0.

Similarly, at L the lower acting along v will produce compression, load acting along the direction of the principal direction v will produce compression. Load acting along the direction of u will produce this is the P by root 2, load acting like this as a P by root 2 load acting like that. So, that is going to also produce compression at L. So, that we compression and compression at L whereas, at N the load acting along v produces compression because, it is about the u axis and load acting along u, will produce tension because it is below the v axis, it will produce tension there.

So, basically now you will find that M would be in tension L would be in compression and the N can be in tension or compression depending upon which is dominating because, it is combination of a branch cell session the compressive stress, that depends how the orientation of the neutral axis is, what is orientation of neutral axis is. So, this kind of analysis you should be able to do to quickly tell whether, a given point will be in tension or compression due to bending stresses.
