Stresses and displacement due to torsion or inflation
Lecture – 87
Governing differential equation and solution

(Refer Slide Time: 00:18)

$$\underline{u} = u_r(r) \underline{e}_r + 0 \underline{e}_\theta + 0 \underline{e}_z$$
 No axial displacement
 No circumferential displacement

$$\underline{\epsilon} = \frac{1}{2} (\underline{\Delta} + \underline{\Delta}^t) = \begin{pmatrix} \frac{du_r}{dr} & 0 & 0 \\ 0 & \frac{u_r}{r} & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

$$\underline{\sigma} = \lambda (\text{tr } \underline{\epsilon}) \underline{1} + 2\mu \underline{\epsilon} = \begin{pmatrix} \sigma_{rr} & \sigma_{r\theta} & \sigma_{rz} \\ \sigma_{\theta r} & \sigma_{\theta\theta} & \sigma_{\theta z} \\ \sigma_{rz} & \sigma_{zr} & \sigma_{zz} \end{pmatrix}$$

$$\left. \begin{aligned} \sigma_{rr} &= (\lambda + 2\mu) \frac{du_r}{dr} + \lambda \frac{u_r}{r} \\ \sigma_{\theta\theta} &= (\lambda + 2\mu) \frac{u_r}{r} + \lambda \frac{du_r}{dr} \\ \sigma_{zz} &= \lambda \left(\frac{du_r}{dr} + \frac{u_r}{r} \right) \end{aligned} \right\} \Rightarrow \text{div}(\underline{\sigma}) = 0$$

Now, you are supposed to find what this radial function u of r of r is.. Further we have run through the procedure of finding the strain, finding the stresses, finding using equilibrium equations, you find the unknown displacement component. So, now the gradient of displacement h is given by from that expression in here $\frac{du}{dr}$ by $\frac{du}{dr}$, that is the only component of stress which is non zero here you add here you add this is a non zero component u r as.

(Refer Slide Time: 00:51)

The image shows a handwritten derivation of the divergence of a vector field \underline{u} in cylindrical coordinates. The vector field is given as $\underline{u} = \text{grad}(u) = \left(\frac{\partial u_r}{\partial r}, \frac{\partial u_\theta}{\partial r}, \frac{\partial u_z}{\partial r}, \frac{\partial u_r}{\partial \theta} - \frac{u_\theta}{r}, \frac{\partial u_\theta}{\partial \theta} + \frac{u_r}{r}, \frac{\partial u_z}{\partial \theta} \right)$. The divergence is then calculated as $\text{div}(\underline{u}) = \left(\frac{\partial}{\partial r} \left(\frac{\partial u_r}{\partial r} + \frac{\partial u_r}{\partial \theta} + \frac{\partial u_r}{\partial z} \right) + \frac{\partial}{\partial \theta} \left(\frac{\partial u_\theta}{\partial r} + \frac{\partial u_\theta}{\partial \theta} + \frac{\partial u_\theta}{\partial z} \right) + \frac{\partial}{\partial z} \left(\frac{\partial u_z}{\partial r} + \frac{\partial u_z}{\partial \theta} + \frac{\partial u_z}{\partial z} \right) \right)$.

Below the equations is a diagram of a cylinder with concentric circles representing different radii. Blue arrows represent radial displacement u_r and green arrows represent circumferential displacement u_θ . The diagram illustrates that there is no axial displacement u_z and no circumferential displacement u_θ .

The displacement vector is given as $\underline{u} = u_r(r) \underline{e}_r + 0 \underline{e}_\theta + 0 \underline{e}_z$. The strain tensor is given as $\underline{\epsilon} = \frac{1}{2} \frac{\partial u_r}{\partial r}$.

Suppose theta is not there this is 0, u theta is 0. So, this is 0 and this is also 0 because that a function of z ok.

So, you have $\frac{\partial u_r}{\partial r}$ by $\frac{\partial u_r}{\partial r}$ 0 0, u theta is not there. So, all this remaining components except $\frac{\partial u_r}{\partial r}$ are 0 because there is no u theta and there is no u z in this problem. So, you have 0, u of r by r 0 0 0 ok. The strain corresponding to this displacement gradient would be $\frac{1}{2} \left(\frac{\partial u_r}{\partial r} + \frac{\partial u_r}{\partial r} \right)$ which will be same as $\frac{\partial u_r}{\partial r}$ in this case, which will be $\frac{1}{2} \left(\frac{\partial u_r}{\partial r} + \frac{\partial u_r}{\partial r} \right)$ ok. Now we will use a constellation for sigma, which is sigma times sigma is (Refer Time: 02:06) constant lambda times trace of epsilon identity plus 2 mu epsilon.

This will give me the non zero components or the diagonal components of the stress, which is radial stress sigma r r this will be nothing, but sigma r r, sigma r theta, sigma r z, sigma r theta, sigma theta theta, sigma theta z, sigma r z, sigma theta z, sigma z z or the cylindrical polar components of the stress and strain components are cylindrical polar components of the strain. So, I am equating this sigma r r with this equation it will be lambda plus 2 mu $\frac{\partial u_r}{\partial r}$ plus lambda times $\frac{\partial u_r}{\partial r}$ ok. Similarly sigma theta theta would be lambda plus 2 mu $\frac{\partial u_r}{\partial r}$ plus lambda times $\frac{\partial u_r}{\partial r}$ and sigma z z would be lambda times $\frac{\partial u_r}{\partial r}$ plus $\frac{\partial u_r}{\partial r}$.

Now I substitute these expressions into divergence of sigma equal to 0 ok. Now divergence of sigma is given by this expression in there. So, is given by the expression in

here ok. Divergence of sigma is given by expression in here here you find that sigma r theta component is 0.

(Refer Slide Time: 03:51)

The image shows a whiteboard with handwritten mathematical derivations. At the top, there is a small diagram of a cylinder with a red arrow pointing outwards, representing the stress tensor. Below it, the divergence of the stress tensor is calculated in cylindrical coordinates. The derivation shows that the divergence of the stress tensor is zero, leading to a system of three equations. The first equation is the radial equilibrium equation, which is simplified to a differential equation for the radial displacement u_r . The second and third equations are the tangential and axial equilibrium equations, which are shown to be zero under the assumption of static equilibrium and no body forces.

$$\text{div}(\underline{\underline{\sigma}}) = \begin{pmatrix} \frac{d\sigma_{rr}}{dr} + \frac{\partial\sigma_{r\theta}}{r\partial\theta} + \frac{\partial\sigma_{rz}}{\partial z} + \frac{\sigma_{rr} - \sigma_{\theta\theta}}{r} \\ \frac{\partial\sigma_{r\theta}}{\partial r} + \frac{\partial\sigma_{\theta\theta}}{r\partial\theta} + \frac{\partial\sigma_{\theta z}}{\partial z} + \frac{2\sigma_{r\theta}}{r} \\ \frac{\partial\sigma_{rz}}{\partial r} + \frac{\partial\sigma_{r\theta}}{r\partial\theta} + \frac{\partial\sigma_{zz}}{\partial z} + \frac{\sigma_{rz}}{r} \end{pmatrix} = \begin{pmatrix} \frac{d\sigma_{rr}}{dr} + \frac{\sigma_{rr} - \sigma_{\theta\theta}}{r} \\ 0 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

Assuming No body forces & Static equilibrium.

$$(\lambda + 2\mu) \frac{d^2 u_r}{dr^2} + \lambda \frac{d}{dr} \left(\frac{u_r}{r} \right) + \frac{2\mu}{r} \left(\frac{du_r}{dr} - \frac{u_r}{r} \right) = 0$$

$$(\lambda + 2\mu) \left[\frac{d^2 u_r}{dr^2} + \frac{d}{dr} \left(\frac{u_r}{r} \right) \right] = 0 \quad \left\{ \therefore \frac{1}{r} \left(\frac{du_r}{dr} - \frac{u_r}{r} \right) = \frac{d}{dr} \left(\frac{u_r}{r} \right) \right\}$$

So, this goes to 0, $r \neq 0$ where σ_{rr} and $\sigma_{\theta\theta}$ are not 0. So, you have for in the first equation you will retain $\frac{d\sigma_{rr}}{dr}$, plus σ_{rr} minus $\sigma_{\theta\theta}$ by r , that will be retained. The second equation you find that $\sigma_{r\theta}$, $\sigma_{\theta\theta}$ is not a function of θ hence this is 0, $\sigma_{\theta z}$ and hence this is 0 this is also 0 in σ_{rz} is 0. So, this equation trivially falls down to 0, in a similar manner the last equation σ_{rz} and σ_{zz} are 0, and σ_{zz} is not a function of z and hence this equation also falls down trivially to 0 ok. We are assuming that there are no body forces acting in the cylinder and the cylinder is in static equilibrium and hence divergence of sigma are to be equal to 0 ok; assuming no body forces and static equilibrium.

Now, what we will do next is, we will substitute for σ_{rr} , $\sigma_{\theta\theta}$ in this expression in here. Next we will substitute σ_{rr} and $\sigma_{\theta\theta}$ into the expression here and will see what is the differential equation are getting. Let us substitute σ_{rr} and $\sigma_{\theta\theta}$ there, I will get $\lambda + 2\mu \frac{d^2 u_r}{dr^2} + \lambda \frac{d}{dr} \left(\frac{u_r}{r} \right) + \frac{2\mu}{r} \left(\frac{du_r}{dr} - \frac{u_r}{r} \right) = 0$.

Now, when rewrite this equation as $\lambda + 2\mu$ $\frac{d^2 u_r}{dr^2} + \frac{d}{dr} \left(\frac{u_r}{r} \right) = 0$. Since I observe that $\frac{1}{r} \frac{d}{dr} \left(\frac{u_r}{r} \right) = \frac{1}{r^2} \left(\frac{du_r}{dr} - \frac{u_r}{r} \right)$ is nothing, but $\frac{d}{dr} \left(\frac{u_r}{r} \right) = \frac{1}{r} \frac{d}{dr} (r u_r)$ since that is that I get this as this.

Now, I know from our restriction on material parameters that, $\lambda + 2\mu$ is not equal to 0.

(Refer Slide Time: 07:07)

The image shows a handwritten derivation on a whiteboard. It starts with the divergence of the stress tensor $\text{div}(\underline{\sigma})$ in spherical coordinates, which is set equal to zero. The components are written as:

$$\text{div}(\underline{\sigma}) = \begin{pmatrix} \frac{\partial \sigma_{rr}}{\partial r} + \frac{\partial \sigma_{r\theta}}{\partial \theta} + \frac{\partial \sigma_{rz}}{\partial z} + \frac{G_{rr}}{r} \\ \frac{\partial \sigma_{r\theta}}{\partial r} + \frac{\partial \sigma_{\theta\theta}}{\partial \theta} + \frac{\partial \sigma_{\theta z}}{\partial z} + \frac{2G_{r\theta}}{r} \\ \frac{\partial \sigma_{rz}}{\partial r} + \frac{\partial \sigma_{r\theta}}{\partial \theta} + \frac{\partial \sigma_{zz}}{\partial z} + \frac{G_{rz}}{r} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

Assuming No body forces & Static Equilibrium.

The derivation then simplifies to the radial component equation:

$$(\lambda + 2\mu) \frac{d^2 u_r}{dr^2} + \lambda \frac{d}{dr} \left(\frac{u_r}{r} \right) + \frac{2\mu}{r} \left(\frac{du_r}{dr} - \frac{u_r}{r} \right) = 0$$

Further simplification leads to:

$$(\lambda + 2\mu) \left[\frac{d^2 u_r}{dr^2} + \frac{d}{dr} \left(\frac{u_r}{r} \right) \right] = 0 \quad \left\{ \because \frac{1}{r} \left(\frac{du_r}{dr} - \frac{u_r}{r} \right) = \frac{d}{dr} \left(\frac{u_r}{r} \right) \right\}$$

Since $\lambda + 2\mu \neq 0$, so,

$$\frac{d^2 u_r}{dr^2} + \frac{d}{dr} \left(\frac{u_r}{r} \right) = 0, \quad \text{Integrating} \Rightarrow \frac{du_r}{dr} + \frac{u_r}{r} = C_1$$

Integrating again:

$$\frac{1}{r} \frac{d}{dr} (r u_r) = C_1 \Rightarrow r u_r = \frac{C_1 r^2}{2} + C_2$$

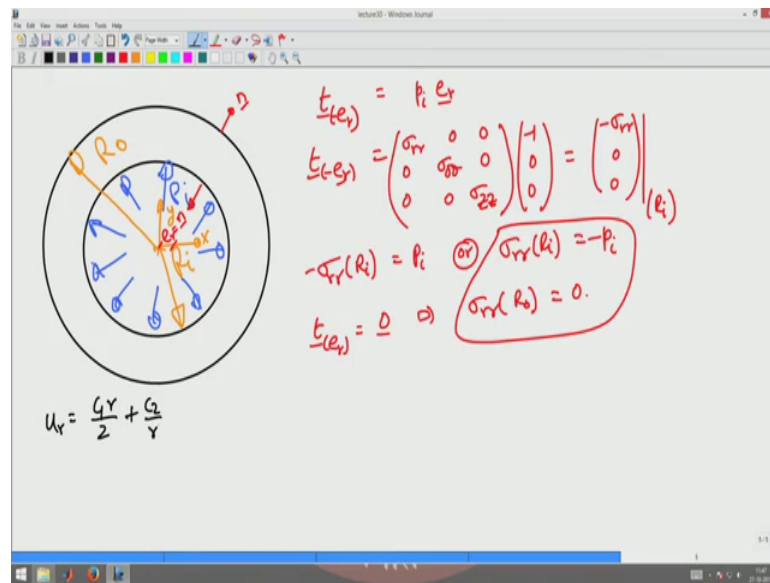

Final result:

$$u_r = \frac{C_1 r}{2} + \frac{C_2}{r}$$

So, I require $\frac{d^2 u_r}{dr^2} + \frac{d}{dr} \left(\frac{u_r}{r} \right)$ to be equal to 0. Now integrating this integrating this, once I get $\frac{du_r}{dr} + \frac{u_r}{r} = C_1$ ok. Now again I realise that I can rewrite this as $\frac{d}{dr} \left(\frac{u_r}{r} \right) = C_1$. So, this will imply integrating this I will get $r u_r = C_1 \frac{r^2}{2} + C_2$ ok. From here I get u_r to be $C_1 \frac{r}{2} + \frac{C_2}{r}$ where I have to find the constant C_1 and C_2 from the boundary conditions ok.

For the problem that we are studying, let us see what the boundary conditions are.

(Refer Slide Time: 08:33)

For this problem let us see what the boundary conditions are. The boundary conditions are I am applying a pressure at the inner surface, this pressure is acting this is the out to normal to that surface is acting opposite to the outward normal to the surface. So, that is a negative stress ok. And this component of stress this normal is nothing, but e_r negative of e_r where e_r is a radial basis for the cylindrical polar coordinate system..

So, this stress is σ_{rr} stress are I can more formally derive the boundary condition as t of e_r the negative face is given by plus $p_i e_r$ right because this acting along the e_r direction ok. Now t of minus e_r is, $\sigma_{rr} \ 0 \ 0 \ \sigma_{\theta\theta} \ 0 \ 0 \ \sigma_{zz}$ this 1 is a state of stress that we got for this problem into minus 1 0 0 this will give me minus $\sigma_{rr} \ 0 \ 0$ at the inner surface, we have already derived the inner surface that is R_i .

So, what I get is, I get minus σ_{rr} at R_i is equal to p_i or σ_{rr} at R_i is minus p_i ok. Now similarly at the outer surface I am offering no traction. So, t's of e_r the outer surface in normal is this normal is that that is a positive e_r dash normal. So, t's of e_r is 0 vector. So, this will imply that σ_{rr} at R_o is equal to 0 ok. I can alternatively I could operate a pressure in the outer surface you know which case what are pressure that I apply in the outer surface should come in here as a pressure that I am applying there ok, but for example, problem here I am assuming it to be 0. So, these are the 2 boundary condition that I have to now enforce ok. I found the displacement field to be I found u_r to be $C_1 r^2 + C_2/r$.

Correspondingly now I go back and substitute this in the expression for the stresses in here the expression for the stress in here at the earlier what this stress stresses are in terms of the constant C 1 and C 2 and radial location r.

(Refer Slide Time: 11:43)

$$u_r = \frac{C_1 r}{2} + \frac{C_2}{r}$$

$$\sigma_{rr} = (\lambda + 2\mu) \left(\frac{C_1}{2} - \frac{C_2}{r^2} \right) + \lambda \left(\frac{C_1}{2} + \frac{C_2}{r^2} \right) = (\lambda + \mu) C_1 - \frac{2\mu C_2}{r^2}$$

$$\sigma_{\theta\theta} = (\lambda + 2\mu) \left(\frac{C_1}{2} + \frac{C_2}{r^2} \right) + \lambda \left(\frac{C_1}{2} - \frac{C_2}{r^2} \right) = (\lambda + \mu) C_1 + \frac{2\mu C_2}{r^2}$$

$$\sigma_{zz} = \lambda \left(\frac{C_1}{2} + \frac{C_2}{r^2} + \frac{C_1}{2} - \frac{C_2}{r^2} \right) = \lambda C_1$$

Applying BC's:

$$\begin{pmatrix} \lambda + \mu & -2\mu/R_i^2 \\ \lambda + \mu & -2\mu/R_o^2 \end{pmatrix} \begin{pmatrix} C_1 \\ C_2 \end{pmatrix} = \begin{pmatrix} -p_i \\ 0 \end{pmatrix} \Rightarrow \begin{pmatrix} C_1 \\ C_2 \end{pmatrix} = \frac{1}{(\lambda + \mu) 2\mu (1/R_i^2 - 1/R_o^2)} \begin{pmatrix} -2\mu/R_i^2 & +2\mu/R_o^2 \\ -2\mu/R_o^2 & -2\mu/R_i^2 \end{pmatrix} \begin{pmatrix} -p_i \\ 0 \end{pmatrix}$$

$$C_1 = \frac{p_i R_i^2}{(\lambda + \mu)(R_o^2 - R_i^2)} \quad \alpha \quad C_2 = \frac{p_i R_i^2 R_o^2}{2\mu(R_o^2 - R_i^2)}$$

$$\sigma_{rr} = \frac{p_i R_i^2}{(R_o^2 - R_i^2)} \left[1 - \left(\frac{R_o}{r} \right)^2 \right]; \quad \sigma_{\theta\theta} = \frac{p_i R_i^2}{R_o^2 - R_i^2} \left[1 + \left(\frac{R_o}{r} \right)^2 \right]$$

So, sigma r r now becomes lambda plus 2 mu C 1 by 2 minus C 2 by r square plus 2 mu plus lambda sorry plus lambda C 1 by 2 plus C 2 by r square which can be written as lambda plus lambda plus mu C 1 minus 2 mu C 2 by r square ok. Similarly the for sigma theta theta becomes lambda plus 2 mu C 1 by 2 plus C 2 by r square plus lambda times C 1 by 2 minus C 2 by r square, which can be written as lambda plus mu C 1 plus 2 mu C 2 by r square and sigma z z now will be lambda times C 1 by 2 plus C 2 by r square plus C 1 by 2 minus C 2 by r square which will be lambda times C 1.

Now, I apply the boundary conditions, sigma r r at r I equal to minus p i sigma r r into R naught equal to 0 to obtain the following equations applying the boundary conditions you get lambda plus mu minus 2 mu by R i square lambda plus mu minus 2 mu by R naught square into C 1 C 2 is equal to minus p i 0.

Now, I solved this equation to get from here C 1 C 2 is 1 by lambda plus mu 2 mu 1 by R i square minus 1 by R naught square into minus 2 mu by R naught square minus 2 mu by R i square minus lambda plus mu and lambda plus mu into into minus p i 0 ok. That gives us the constant C 1 to be p i R i square divided by lambda plus mu into R naught

square minus R_i square. And C_2 would be $\frac{1}{2} \mu R_0$ square minus R_i square plus R_0 square.

Now, correspondingly I have found the constants I can write these stresses σ_{rr} would be $\frac{p_i R_i^2}{R_0^2 - R_i^2}$ and $\sigma_{\theta\theta}$ would be $\frac{p_i R_i^2}{R_0^2 - R_i^2} \left(1 + \frac{R_0^2}{r^2} \right)$.

(Refer Slide Time: 16:05)

$$C_1 = \frac{p_i R_i^2}{(\lambda + \mu)(R_0^2 - R_i^2)} \quad \alpha \quad C_2 = \frac{p_i R_0^2 R_i^2}{2\mu(R_0^2 - R_i^2)}$$

$$\sigma_{rr} = \frac{p_i R_i^2}{(R_0^2 - R_i^2)} \left[1 - \left(\frac{R_0}{r} \right)^2 \right]; \quad \sigma_{\theta\theta} = \frac{p_i R_i^2}{R_0^2 - R_i^2} \left[1 + \left(\frac{R_0}{r} \right)^2 \right]$$

$$\sigma_{zz} = \frac{\lambda}{(\lambda + \mu)} \left(\frac{p_i R_i^2}{R_0^2 - R_i^2} \right) = \nu \left(\frac{p_i R_i^2}{R_0^2 - R_i^2} \right)$$

$$\sigma_{\theta\theta}(R_i) = \frac{p_i (R_0^2 + R_i^2)}{(R_0^2 - R_i^2)}; \quad \sigma_{\theta\theta}(R_0) = \frac{2p_i R_i^2}{(R_0^2 - R_i^2)}$$

$$\epsilon_{rr} = \frac{du_r}{dr} = \frac{C_1}{r} - \frac{C_2}{r^3}$$

Similarly, σ_{zz} would be $\frac{\lambda}{\lambda + \mu} \nu \frac{p_i R_i^2}{R_0^2 - R_i^2}$.

From the definition of Poisson's ratio you know that this is nothing, but Poisson's ratio times $\frac{p_i R_i^2}{R_0^2 - R_i^2}$. Now let us plot the variation of σ_{rr} and $\sigma_{\theta\theta}$ and σ_{zz} along the thickness of the cylinder. Now first let's plot the variation of σ_{rr} across the thickness of the cylinder. You know that at an inner surface when $r = R_i$, σ_{rr} is minus p_i . So, this is minus p_i and at the outer surface when $r = R_0$, σ_{rr} becomes 0. So, it varies from p_i minus p_i to 0 like this $\frac{1}{r^2}$. So, it will be a hyperbolic kind of a variation there this is σ_{rr} variation.

On the other hand $\sigma_{\theta\theta}$ now let's plot $\sigma_{\theta\theta}$ variation. $\sigma_{\theta\theta}$ at R_i would be $\frac{p_i R_0^2 + R_i^2}{R_0^2 - R_i^2}$.

minus R_i^2 and $\sigma_{\theta\theta}$ at R_o would be $2 p_i R_i^2$ divided by $R_o^2 - R_i^2$. You can see that it decreases from the value at the inner surface to the outer surface, but is not 0 and it is positive throughout the domain. So, $\sigma_{\theta\theta}$ will vary like that wherein this is $\sigma_{\theta\theta}$ at R_i and this is $\sigma_{\theta\theta}$ at R_o .

Now, the point is the hoop stress or $\sigma_{\theta\theta}$ stress is tensile in nature ok. And the actual stress is constant over the entire cross section it does not vary radially that is what we got from our derivation. Now let us understand why there is actual stress and radial stress developed in the cross section ok. Now because hoop stress is tensile due to Poisson's effect there will be a lateral contraction along the thickness direction and the axial direction. But in the axial direction what you have done is we have fixed a length to be a constant since the length has been fixed to be constant, there should be axial tension coming in to maintain the constant length and hence you have σ_{zz} which is a tensile stress which is a constant stress across the cross section ok.

Similarly, you will find that ϵ_{rr} is $\frac{du}{dr}$ is not 0 ok. $\frac{du}{dr}$ is $C_1 \frac{1}{2r} - C_2 \frac{1}{r^2}$ which has some value which is not zero and hence what happens is there will be a thickness change in the cross section. So, what you have seen in this lecture is, you have seen how to analyze pressure vessels thick wall pressure vessels to be more specific we saw what the displacement field is, and we saw how to get the stresses and we saw how to get the stresses in a thick walled cylinder. We will stop here for today.

Thank you.
