**Lecture – 35**  
**Models of Electrical Double Layer: Gouy Chapman Theory - 1**

So we will continue with module 4. In today's lecture we will try and look at 2 aspects, one is models for double layers looking at Gouy Chapman theory and hopefully if we have some time we will also look at structure of electrical double layers.

**(Refer Slide Time: 00:33)**

**Potential distribution near a charged planar surfaces** – Solution of PB equation with the low potential limitation – Debye Hückel Theory

Poisson equation (1D)

$$\frac{d^2\psi}{dx^2} = -\frac{\rho^*}{\epsilon}$$

$$\psi = \psi_0 \exp(-\kappa x)$$

Where

$$\kappa = \left( \frac{e^2}{\epsilon k_B T} \left[ \sum_i n_{i0} z_i^2 \right] \right)^{1/2}$$

So what we have done so far is to look at potential distribution near a planar charge surface. In that context, we have looked at solution of Poisson Boltzmann equation. However, with the limitation that we are only considering the low potential case which is what is called as a Debye Huckel theory. In which we started off with one dimensional Poisson Boltzmann equation. And then we showed that psi essentially goes as psi naught exponent minus Kappa x, where Kappa is given by this particular expression.

**(Refer Slide Time: 01:24)**

**Potential distribution near a charged planar surfaces – GOUY-CHAPMAN THEORY – Solution of PB equation without the low potential limitation**

Poisson equation (1D)

$$\frac{d^2\psi}{dx^2} = -\frac{\rho^*}{\epsilon}$$

So now what we want to do today is to essentially take out this limitation of low potential that means, we would like to obtain a solution of the Poisson Boltzmann equation without the low potential limitation that is what we would like to do. Again the starting expression is going to be one dimensional Poisson Boltzmann equation, because we are assuming that psi varies only in the x direction. That is we are only considering that psi is a function of x alone.

(Refer Slide Time: 02:05)

**Potential distribution near planar surfaces – GOUY-CHAPMAN THEORY – Solution of PB equation without the low potential limitation**

Consider the Poisson-Boltzmann equation (1D)

$$\frac{d^2\psi}{dx^2} = -\frac{e}{\epsilon} \sum_i z_i n_{i0} \exp\left(-\frac{z_i e \psi}{k_B T}\right)$$

For symmetric z:z type electrolyte: The Gouy-Chapman expression for the variation of potential within the double layer is:

$$\psi = \psi_0 \exp(-\kappa x)$$

$$\psi = \frac{\left[ \exp\left(\frac{ze\psi}{2k_B T}\right) - 1 \right]}{\left[ \exp\left(\frac{ze\psi}{2k_B T}\right) + 1 \right]} \quad \text{and} \quad \psi_0 = \frac{\left[ \exp\left(\frac{ze\psi_0}{2k_B T}\right) - 1 \right]}{\left[ \exp\left(\frac{ze\psi_0}{2k_B T}\right) + 1 \right]}$$

And the solution for this particular case is given by what is called as a Gouy Chapman Theory. So for that we will again solve one dimensional Poisson Boltzmann equation and it turns out that for z is to z electrolyte again the dependence of potential with separation distance is still going to be exponential and is given by gamma = gamma naught exponent minus Kappa x, where gamma is exponent z e psi / 2 k<sub>B</sub> T - 1 divided by exponent z e psi 2 k<sub>B</sub> T + 1.

And similarly, gamma naught is same as it takes the same similar functional form as gamma with psi replaced by a psi naught. So that is what we are going to derive in today's lecture.

(Refer Slide Time: 03:00)

### GOUY-CHAPMAN THEORY

Consider the Poisson-Boltzmann equation (1D)

$$\frac{d^2\psi}{dx^2} = -\frac{e}{\epsilon} \sum_i z_i n_{i\infty} \exp\left(-\frac{z_i e\psi}{k_B T}\right)$$

Multiply both sides with

$$2 \frac{d\psi}{dx}$$

$$2 \frac{d\psi}{dx} \left( \frac{d^2\psi}{dx^2} \right) = 2 \frac{d\psi}{dx} \left[ -\frac{e}{\epsilon} \sum_i z_i n_{i\infty} \exp\left(-\frac{z_i e\psi}{k_B T}\right) \right]$$

$$\frac{d}{dx} \left[ \left( \frac{d\psi}{dx} \right)^2 \right] = \frac{d}{dx} \left[ \frac{2k_B T}{\epsilon} \sum_i n_{i\infty} \exp\left(-\frac{z_i e\psi}{k_B T}\right) \right]$$

So again we will start with Poisson Boltzmann equation one dimensional case. And if you remember this, so we had  $d^2\psi / dx^2 = -\rho^*/\epsilon$ , instead of  $\rho^*$ , we have used the Boltzmann factor and then we have written an expression for  $\rho^*$ , which essentially is a summation for all the species that I have in the solution, I would have to sum up the contribution from all the ions that I have in the solution.

Which is essentially is  $e z_i n_i$  and with  $n_i$  being given by the Boltzmann factor. So what we will do is we will start with this expression. And we will do some simple manipulations so we are going to multiply both the sides of this equation by  $2 d\psi / dx$ , so that is what we have on the left hand side. And that is what we have on the right hand side as well.

Now if you look at the left hand side, I can write this as  $d / dx$  of  $(d\psi / dx)^2$ . So if I differentiate this function, so what I will get is, I get 2 times that is 2 here, times  $d\psi / dx$ , multiplied by  $d^2\psi / dx^2$ . So that is the left hand side term, and the right hand side term, I can write this as  $d / dx$  of  $2 k_B T / \epsilon$  into  $\sum_i n_{i\infty} \exp(-z_i e\psi / k_B T)$ .

So if I differentiate this term, so the first term remains the same  $k_B T$  divided by epsilon, and what you have here, so I am going to have  $\sum_i n_i$  infinity, and if I am going to replace, differentiate this term is still going to be exponent minus  $z_i e \psi / k_B T$  multiplied by, so it is going to be multiplied by  $z_i e$  divided by  $k_B T$ . And this  $k_B T$ ,  $k_B T$  gets cancelled, and so therefore and you have  $e$  here that is the  $e$  there and I have  $\psi$  sorry epsilon. So I have  $e / \epsilon$  and  $z_i$  is here  $\sum_i n_i$  infinity that is this term.

And of course, this term is as it is. And of course I have 2. So essentially, this by this simple manipulation, I can write the one dimensional Poisson Boltzmann equation as  $d / dx$  of  $(d \psi / dx)^2$  is equal to  $d / dx$  of  $2 k_B T$  divided by epsilon summation  $\sum_i n_i$  infinity exponent of minus  $z_i \psi$  divided by  $k_B T$ .

**(Refer Slide Time: 06:12)**

#### GOUY-CHAPMAN THEORY

Integrate the following equation:

$$\frac{d}{dx} \left[ \left( \frac{d\psi}{dx} \right)^2 \right] = \frac{d}{dx} \left[ \frac{2k_B T}{\epsilon} \sum_i n_{i\infty} \exp \left( -\frac{z_i e \psi}{k_B T} \right) \right]$$

$$\left( \frac{d\psi}{dx} \right)^2 = \frac{2k_B T}{\epsilon} \sum_i n_{i\infty} \exp \left( -\frac{z_i e \psi}{k_B T} \right) + \text{constant}$$

So now if I can integrate this expression, so I can integrate this on both the sides. So what I will be ending up with this  $(d \psi / dx)^2$  is equal to this plus a constant term. So we can evaluate the constant fairly easily.

**(Refer Slide Time: 06:32)**

## GOUY-CHAPMAN THEORY

Evaluation of integration constant:

$$\left(\frac{d\psi}{dx}\right) = \frac{2k_B T}{\epsilon} \sum_i n_{i\infty} \exp\left(-\frac{z_i e \psi}{k_B T}\right) + \text{constant}$$

Since  $\psi = 0$  at  $x = \infty$   
 $\frac{d\psi}{dx} = 0$  at  $x = \infty$

Therefore, integration constant is

$$\text{constant} = -\frac{2k_B T}{\epsilon} \sum_i n_{i\infty}$$

We know that  $\psi = 0$  at  $x = \text{infinity}$  and  $d\psi / dx = 0$ . Therefore, because  $\psi = 0$ , you can also say that  $d\psi / dx = 0$  at  $x = \text{infinity}$ . So, if I substitute for these conditions, so this is you know 0 and if I substitute  $\psi = 0$ , this term becomes 1. Therefore, essentially I have  $2k_B T$  divided by  $\epsilon$  summation  $i n_i$  infinity and plus constant is equal to 0. Therefore the constant essentially becomes minus  $2k_B T$  divided by  $\epsilon$  summation  $i n_i$  infinity. So therefore, we have been able to evaluate the constant. I can substitute for the constant.

**(Refer Slide Time: 07:28)**

## GOUY-CHAPMAN THEORY

Therefore

$$\left(\frac{d\psi}{dx}\right)^2 = \frac{2k_B T}{\epsilon} \sum_i n_{i\infty} \exp\left(-\frac{z_i e \psi}{k_B T}\right) - \frac{2k_B T}{\epsilon} \sum_i n_{i\infty}$$

$$\left(\frac{d\psi}{dx}\right)^2 = \frac{2k_B T}{\epsilon} \sum_i n_{i\infty} \left[ \exp\left(-\frac{z_i e \psi}{k_B T}\right) - 1 \right]$$

For z:z electrolyte,

$$\left(\frac{d\psi}{dx}\right)^2 = \frac{2k_B T n_{\infty}}{\epsilon} \left[ \exp\left(-\frac{ze\psi}{k_B T}\right) - 1 + \exp\left(\frac{ze\psi}{k_B T}\right) - 1 \right]$$

So therefore, I could write  $d\psi / dx$  whole square as the first term minus the constant term and because I have  $2k_B T$  by  $\epsilon$  summation  $i n_i$  infinity as a common I can take it out. Therefore, in the parenthesis I will have exponent minus  $z_i e \psi$  divided by  $k_B T - 1$ . Now I can simplify now because we are considering a specific case of  $z$  is to  $z$  electrolyte, what I

can do is I can take this term and then whenever I have z is to z electrolyte there is going to be z plus and z minus type of ions.

Therefore, there so because it is taking a symmetric electrolyte case, what I can do is I can wherever I have z in, I can substitute for plus 1 as well as z = -1. So that I count for both the co ions and the counter ions in the solution. Therefore, the first term remains the same and exponent of if I substitute z\_i as plus z therefore, the first term is going to be exponent of minus z e psi divided by k\_B T - 1.

And the next term if I substitute for z\_i to be minus z, so therefore, the next term essentially become the exponent of z e psi divided by k\_B T. So, the substitution of z = +1, z = -1 is specifically for 1 is to 1 electrolyte. If you have a 2 is to 2 electrolyte, I would have to substitute z = +2 and z = -2, but because we are considering the case of a general z is to z electrolyte.

Therefore, it makes sense to replace z\_i with minus z\_i and z\_i with plus z\_i. Therefore, d psi / dx whole square essentially becomes 2 k\_B T and infinity divided by epsilon into exponent minus z e psi divided by k\_B T - 1 + exponent Z e psi divided by k\_B T - 1. The reason why we have taken n\_i infinity out of the summation sign is because for a given concentration n\_i for both plus z and for minus z ions is essentially the same. Therefore, I can actually take it out of the summation term and it will become n infinity.

**(Refer Slide Time: 10:17)**

### GOUY-CHAPMAN THEORY

For z:z electrolyte,

$$\left(\frac{d\psi}{dx}\right)^2 = \frac{2k_B T n_\infty}{\epsilon} \left[ \exp\left(-\frac{ze\psi}{k_B T}\right) + \exp\left(\frac{ze\psi}{k_B T}\right) - 2 \right]$$

$$\left[ \exp\left(-\frac{ze\psi}{2k_B T}\right) - \exp\left(\frac{ze\psi}{2k_B T}\right) \right]^2$$

*(a - b)^2 = a^2 + b^2 - 2ab*

$$\left[ \exp\left(\frac{ze\psi}{2k_B T}\right) \right]^2 + \left[ \exp\left(-\frac{ze\psi}{2k_B T}\right) \right]^2 - 2 \exp\left(-\frac{ze\psi}{2k_B T}\right) \exp\left(\frac{ze\psi}{2k_B T}\right)$$

So, now that we have this. So, what I can do is so this is what we had earlier. So, there is minus 1 here and minus 1 that becomes minus 2 and in the parenthesis you have exponent of minus z e psi divided by k<sub>B</sub> T + exponent of z e psi / k<sub>B</sub> T. If you look this up, you can write this as exponent minus z e psi divided by 2 K<sub>B</sub> T - exponent z e psi divided by 2 K<sub>B</sub> T whole square.

These are the form a - b whole square, which is same as a square + b square - 2ab, therefore I can recover this expression. So that I have the first term whole square that is this. So, if you look at this expression, so I have exponent z e psi divided by 2 k<sub>B</sub> T whole square. Now, I can simplify this. I can take the 2 in the numerator, this, this gets cancelled essentially I have the first term.

Similarly, that is this term similarly, so I have again I can take the 2 in the numerator, so I can this, this gets cancelled. So, I essentially have the first term here and the second term there. And if you look at this, this essentially is minus 2 times exponent - z e psi divided by 2 k<sub>B</sub> T + z e psi / 2 k<sub>B</sub> T essentially it is exponent of 0 which is 1. Therefore, I recover the minus 2.

**(Refer Slide Time: 12:09)**

### GOUY-CHAPMAN THEORY

Therefore, for z:z electrolyte,

$$\left(\frac{d\psi}{dx}\right)^2 = \frac{2k_B T n_\infty}{\epsilon} \left[ \exp\left(-\frac{ze\psi}{2k_B T}\right) - \exp\left(\frac{ze\psi}{2k_B T}\right) \right]^2$$

Let  $y = \frac{ze\psi}{k_B T} \rightarrow \psi = \frac{y k_B T}{ze}$

$$\left(\frac{d}{dx} \left(\frac{k_B T}{ze} y\right)\right)^2 = \frac{2k_B T n_\infty}{\epsilon} \left[ \exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right) \right]^2$$

$$\left(\frac{k_B T}{ze}\right)^2 \left(\frac{dy}{dx}\right)^2 = \frac{2k_B T n_\infty}{\epsilon} \left[ \exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right) \right]^2$$

So therefore, so I can express this particular expression as d psi / dx whole square is 2 k<sub>B</sub> T n infinity divided by epsilon into exponent - z e psi by 2 k<sub>B</sub> T - exponent z e psi divided by 2 k<sub>B</sub> T the whole square. Now again, we are going to do some more manipulation. So we are going to assume or we are going to put z as z e psi divided by k<sub>B</sub> T, this is a simple substitution. So therefore, from this what I get is I get psi to be y k<sub>B</sub> T divided by z e.

So therefore, I can replace for psi in terms of y, so I have d / d x, instead of psi, I am going to replace it with  $y k_B T$  divided by  $z e$ , that is this term multiplied by y, and the right hand side becomes  $2 k_B T$  an infinity / epsilon into exponent - y / 2 - exponent of y / 2, because we are substituted this to be y, therefore I have y here and I have 2 in the denominator, the same thing is also true for this case.

So therefore, and because for a given electrolyte and given temperature  $k_B T$  divided by  $z e$  is constant. I am going to take  $k_B T$  square divided by  $k_B T$  divided by  $z e$  whole square outside. So I have  $dy / dx$  whole square =  $2 k_B T$  n infinity / epsilon multiplied by this term.

**(Refer Slide Time: 13:50)**

### GOUY-CHAPMAN THEORY

Therefore, for z:z electrolyte,

$$\left(\frac{k_B T}{ze}\right)^2 \left(\frac{dy}{dx}\right)^2 = \frac{2k_B T n_\infty}{\epsilon} \left[ \exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right) \right]^2$$

$$\left(\frac{dy}{dx}\right)^2 = \frac{2z^2 e^2 n_\infty}{\epsilon k_B T} \left[ \exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right) \right]^2$$

Therefore,

$$\left(\frac{dy}{dx}\right) = \left(\frac{2z^2 e^2 n_\infty}{\epsilon k_B T}\right)^{1/2} \left[ \exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right) \right]$$

That is of course which is valid only for a z is to z electrolyte and at a given temperature. So and what I can do is I can take the square root on both the sides of this expression, so I will end up with  $dy / dx$  on the left hand side and this term raised to the power one and a half and this and the square gets cancelled, I have exponent of minus y divided by 2 - exponent of y divided by 2.

**(Refer Slide Time: 14:25)**

## GOUY-CHAPMAN THEORY

Therefore, for z:z electrolyte,

$$\left(\frac{dy}{dx}\right) = \left(\frac{2z^2 e^2 n_\infty}{\epsilon k_B T}\right)^{1/2} \left[ \exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right) \right]$$

We know that:

$$\kappa^2 = \frac{e^2}{\epsilon k_B T} \left[ \sum_i n_i z_i^2 \right]$$

For z:z electrolyte

$$\kappa^2 = \frac{e^2}{\epsilon k_B T} \left[ n_\infty z^2 + n_\infty z^2 \right] = \frac{2e^2 z^2 n_\infty}{\epsilon k_B T}$$

⏪ ⏩ ⏴ ⏵ ⏶ ⏷

Now, if you look at, if you take a closer look at this expression, it turns out that you can relate that to the Kappa. So what we know from the definition of Kappa is that Kappa square = e square divided by epsilon k<sub>B</sub> T multiplied by summation of i n<sub>i</sub> infinite into z<sub>i</sub> square. Now because we are considering z is to z electrolyte, I can write this as n infinity times plus z whole square plus n infinity into minus z whole square.

Therefore, I will have 2 times z square into n i infinity that comes from the term in the parenthesis and I have of course, e square divided by epsilon k<sub>B</sub> T. So, now if you look at this expression and compare it to this, so what you essentially have is, if I take the square on both sides, I have what I have is Kappa is same as this term to the ratio of one and a half. So therefore, so this particular expression which is valid for z is to z electrolyte.

**(Refer Slide Time: 15:41)**

## GOUY-CHAPMAN THEORY

Therefore, for z:z electrolyte,

$$\left(\frac{dy}{dx}\right) = \left(\frac{2z^2 e^2 n_\infty}{\epsilon k_B T}\right)^{1/2} \left[ \exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right) \right]$$

$$\left(\frac{dy}{dx}\right) = \kappa \left[ \exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right) \right]$$

$$\left[ \exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right) \right] = \kappa dx$$

I can write it as  $dy / dx$  is equal to  $\kappa$  times exponent of  $-y / 2$  - exponent of  $y / 2$ . Now I can separate the variables. So I have  $dy$  the terms with  $y$  on the one on one side I can just rearrange this you know a bit. So therefore, I end up with  $dy$  divided by exponent of  $-y / 2$  - exponent  $-y / 2 = \kappa$  times  $dx$ .

**(Refer Slide Time: 16:14)**

The slide shows the following derivations:

Therefore, for  $z:z$  electrolyte,

$$\frac{dy}{\exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right)} = \kappa dx$$

Let  $u = e^{y/2}$

$$\frac{du}{dy} = e^{y/2} \cdot \frac{1}{2} \Rightarrow 2du = e^{y/2} dy \Rightarrow dy = 2e^{-y/2} du$$

$$\frac{dy}{\exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right)} = \frac{2e^{-y/2} du}{e^{-y/2} - e^{y/2}} = \frac{2du}{e^{y/2} [e^{-y/2} - e^{y/2}]}$$

And which if you want to evaluate this further, again we are going to substitute for  $u$  as  $e^{y/2}$  therefore,  $du / dy$  is  $e^{y/2}$  divide multiply by one and a half. So therefore,  $2$  times  $du$ , I can cross multiply them,  $2$  times  $du$  is  $e^{y/2}$  times  $dy$ , therefore  $dy$  essentially becomes  $2 e^{-y/2}$  into  $du$ . So therefore for  $dy$ , we are going to substitute it as  $2$  times  $e^{-y/2}$  into  $du$ .

And this because we are substituted, so therefore exponent of  $-y / 2$  - exponent of  $y / 2$  they remain the same, so therefore now what I can do is we could take this term to the denominator. Therefore I have  $2 dy$  multiplied by  $e^{y/2}$  multiplied by  $e^{-y/2} - e^{y/2}$ . So, if I take  $e^{y/2}$ .

**(Refer Slide Time: 17:32)**

UY-CHAPMAN THEORY

$$\frac{dy}{\exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right)} = \frac{2du}{e^{y/2} [e^{-y/2} - e^{y/2}]} = \frac{2du}{1 - e^y}$$

$$\frac{dy}{\exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right)} = \frac{2du}{1 - u^2} = \frac{du}{1+u} + \frac{du}{1-u}$$

*Handwritten notes:  $u = e^{y/2}$ ,  $du = \frac{1}{2}e^{y/2} dy$*

Again inside the parenthesis so I essentially have  $e^{y/2} - e^{-y/2}$ . So, this becomes  $1 - e^y$  and  $e^{y/2} - e^{-y/2}$  essentially is  $e^{y/2}$  itself. So therefore,  $dy$  divided by exponent of minus  $y/2$  - exponent  $y/2$  becomes 2 times  $du$  divided by it was actually  $1 - e^y$  and because  $u$  is  $e^{y/2}$  essentially this becomes  $1 - u^2$  which I can write it as  $du$  divided by  $1 + u$  +  $du$  divided by  $1 - u$ . So therefore, if I sum, if I simplify this it becomes  $du$  times  $1 + u + 1 - u$  divided by  $1 - u^2$  this gets cancelled, essentially you end up with what you had earlier.

(Refer Slide Time: 18:36)

UY-CHAPMAN THEORY

Therefore,  $\frac{dy}{\exp\left(-\frac{y}{2}\right) - \exp\left(\frac{y}{2}\right)} = \kappa dx$

can be re-casted as:  $\left(\frac{du}{1+u} + \frac{du}{1-u}\right) \kappa dx$

Integrating gives:  $\ln(1+u) - \ln(1-u) = \kappa x + \text{constant}$

$$\ln \frac{(1+u)}{(1-u)} = \kappa x + \text{constant}$$

So therefore, if you have been able to simplify this, we have been able to recast this expression as  $du / (1 + u) + du / (1 - u) = \kappa dx$ . So, I can integrate this easily. So, if I integrate this what I essentially end up with is  $\ln(1 + u) - \ln(1 - u) = \kappa x + \text{constant}$ . Therefore,  $\ln(1 + u) / (1 - u) = \kappa x + \text{constant}$ .

(Refer Slide Time: 19:14)

DUY-CHAPMAN THEORY

$$\ln \frac{(1+u)}{(1-u)} = Kx + \text{constant}$$

Equation of integration constant:

$$y = \frac{ze\psi}{k_B T} \Rightarrow u = e^{\frac{ze\psi/2}{k_B T}}$$

At  $x=0$ ,  $\psi = \psi_0$

$$y_0 = \frac{ze\psi_0}{k_B T} \Rightarrow u_0 = e^{y_0/2}$$

Therefore,

$$\text{constant} = \ln \frac{(1+u_0)}{(1-u_0)}$$

So, I can integrate again, evaluate the constants we have substituted  $u$  as  $e$  power  $y / 2$  and therefore,  $y$  becomes  $z e \psi$  divided by  $k_B T$  that is what we have done. So, if you go back so it is  $u = e$  power  $y / 2$  and so therefore, we substituted  $y$  to be  $z e \psi$  divided by  $k_B T$ . So therefore, so this is comes from the substitution that we have done. Therefore,  $u$  essentially becomes  $e$  power instead of  $y$  I am going to have  $z e \psi$  divided by  $k_B T$  and of course, I have the one over 2 term there.

Therefore,  $u$  becomes  $e$  power  $z e \psi$  divided by  $2 k_B T$ . We know that at  $x = 0$  that means; if I have a charged substrate and if this is how the  $x$  varies from the surface at  $x = 0$ , the potential is  $\psi_0$ . So, if we have that, so now and therefore at  $x = 0$   $y_0$  becomes  $z e \psi_0$  divided by  $k_B T$  and  $u_0$  becomes  $e$  power  $y_0$  divided by 2. So, we are essentially re evaluating all the initial conditions and the boundary conditions in terms of  $y_0$  and  $u_0$ . So therefore, if I substitute for  $x = 0$ , so this term goes away and what I end up with this the constant =  $\ln$  of  $1 + u_0$  divided by  $1 - u_0$ .

(Refer Slide Time: 21:15)

UY-CHAPMAN THEORY

$$\ln \frac{(1+u)}{(1-u)} = \kappa x + \ln \frac{(1+u_0)}{(1-u_0)}$$

$$\ln \frac{(1+u)}{(1-u)} - \ln \frac{(1+u_0)}{(1-u_0)} = \kappa x$$

$$\ln \frac{(1+u)(1-u_0)}{(1-u)(1+u_0)} = \kappa x$$

$$\ln \frac{(u+1)(u_0-1)}{(u-1)(u_0+1)} = \kappa x$$

*Handwritten notes:*  
 $\ln x - \ln y = \ln \frac{x}{y}$   
 $\frac{f(u_0-1)}{r(u-1)}$

So therefore, we end up with  $\ln$  of  $1 + u$  divided by  $1 - u = \text{Kappa } x + \ln$  of  $1 + u$  divided by  $1 - u$ . I can take this on to the other side and if I again use the condition that  $\ln$  of  $x - \ln$  of  $y = \ln$  of  $x / y$ . So therefore, I have this term here and because it is  $y$  divided by  $y$ , so this you know is, you can notice  $1 - u$  is in the numerator and  $1 + u$  is in the denominator. So, what we can do here is that I can if you look at these terms, I can write this as minus of  $u$  naught - 1. I can write this as minus of  $u - 1$  this gets cancelled.

Therefore, what I end up with this  $1 + u$  or  $u + 1$  that remains as it is and  $1 - u$  I can write it as  $u$  naught - 1 and  $1 - u$  I can write it as  $u - 1$ . So therefore,  $\ln$  of  $u + 1$  divided by  $u$  naught - 1 whole divided by  $u - 1$  multiplied by  $u$  naught + 1 is  $\text{Kappa } x$ .

**(Refer Slide Time: 22:46)**

UY-CHAPMAN THEORY

$$\ln \frac{(u+1)(u_0-1)}{(u-1)(u_0+1)} = \kappa x$$

*Handwritten notes:*  
 $u = e^{y/2}$      $y = \frac{ze\psi}{k_B T}$   
 $\ln \left( \frac{(e^{y/2}+1)(e^{y_0/2}-1)}{(e^{y/2}-1)(e^{y_0/2}+1)} \right)$

$$\frac{(\exp(ze\psi / 2k_B T) + 1)(\exp(ze\psi_0 / 2k_B T) - 1)}{(\exp(ze\psi / 2k_B T) - 1)(\exp(ze\psi_0 / 2k_B T) + 1)} = \kappa x$$

And, and so of course, we would have to obtain an expression in terms of psi and psi naught. Therefore, we could do again substitute back. So, because u is e power y / 2 and y is z e psi divided by k<sub>B</sub> T, I can write this u as e power y / 2 + 1 times e power y naught / 2 - 1 whole divided by, so maybe let me just do a better job. So, I can substitute, I can write this as ln of e power y / 2 + 1 multiplied by e power y naught / 2 - 1 divided by e power y / 2 - 1 times e power y naught / 2 - 1.

And because y is z e psi divided by k<sub>B</sub> T, I can substitute again for y here. So, essentially I end up with ln of exponent of z e psi divided by 2 k<sub>B</sub> T + 1 times z e psi naught because you have y naught here, I have z e psi naught divided by 2 k<sub>B</sub> T - 1 whole divided by exponent of z e psi / 2 k<sub>B</sub> T - 1 and that will be equal to Kappa x.

**(Refer Slide Time: 24:19)**

DRY-CHAPMAN THEORY

$$\frac{\exp(z e \psi / 2 k_B T) + 1}{\exp(z e \psi_0 / 2 k_B T) + 1} \cdot \frac{\exp(z e \psi / 2 k_B T) - 1}{\exp(z e \psi_0 / 2 k_B T) - 1} = \exp(\kappa x)$$

$$\frac{\exp(z e \psi / 2 k_B T) - 1}{\exp(z e \psi_0 / 2 k_B T) - 1} \cdot \frac{\exp(z e \psi / 2 k_B T) + 1}{\exp(z e \psi_0 / 2 k_B T) + 1} = \exp(-\kappa x)$$

$$\frac{\gamma}{\gamma_0} = \exp(-\kappa x)$$

$$\gamma = \gamma_0 \exp(-\kappa x)$$

So, again some simple rearrangements I can put together all the psi terms together and all the psi naught terms together. Therefore, gamma divided by gamma naught is exponent of minus Kappa x. Therefore, gamma = gamma naught exponent - Kappa x.

**Potential distribution near planar surfaces –  
GOUY-CHAPMAN THEORY – Solution of PB  
Equation without the low potential limitation**

Consider the Poisson-Boltzmann equation (1D)

$$\frac{d^2\psi}{dx^2} = -\frac{e}{\epsilon} \sum_i z_i n_{i\infty} \exp\left(-\frac{z_i e\psi}{k_B T}\right)$$

symmetric z:z type electrolyte: The Gouy-Chapman expression for variation of potential within the double layer is:

$$\psi = \psi_0 \exp(-\kappa x)$$

$$\gamma = \frac{\left[ \exp\left(\frac{ze\psi}{2k_B T}\right) - 1 \right]}{\left[ \exp\left(\frac{ze\psi}{2k_B T}\right) + 1 \right]} \quad \text{and} \quad \gamma_0 = \frac{\left[ \exp\left(\frac{ze\psi_0}{2k_B T}\right) - 1 \right]}{\left[ \exp\left(\frac{ze\psi_0}{2k_B T}\right) + 1 \right]}$$

Where gamma and gamma naught are given by these expressions, so therefore, we have been able to show, we have been able to obtain what is called as a Gouy Chapman theory or Gouy Chapman expression that was derived by Gouy and Chapman for how the potential varies with separation distance without limiting to the case of low potential that means this expression is valid for any situation except for the fact that we will still have to consider the symmetric z is to z type of electrolytes.
