

An Introduction to Programming through C++
Professor Abhiram G. Ranade
Department of Science and Engineering
Indian Institute of Technology Bombay
Lecture No 26 Part - 1
A Graphical Editor and Solver for Circuits

Hello and welcome to the NPTEL course on an Introduction to Programming through C++. I am Abhiram Ranade. Today we are going to continue our discussion of medium size programs and we are going to write a program which will be a graphical editor and solver for the circuits.

(Refer Slide Time: 00:37)

Introduction

- Computers are often used for design:
 - Circuits, mechanical objects, chemical plants, ...
- CAD (Computer Aided Design) systems employ GUI (Graphical User Interfaces)
 - "Buttons" are clicked to tell the computer what you want to happen
 - "Menus" ..
- Our goal today:
 - Write a baby computer aided design program with a GUI.
 - It will design and solve very simple circuits.

So, I should point out I should observe that computers are often used for designing various objects, circuits, mechanical objects, chemical plants, and lots of other things. CAD or Computer Aided Design systems, employ graphical user interfaces which are often abbreviated as GUI. And you have already seen this in our IDE, a there are buttons and you have clicked buttons to tell the computer what you want to happen, or you may also have menus. So, our goal for today is to figure out how these things are actually implemented. And we will be doing a very preliminary a baby computer aided design program using which will have a graphical user interface. And, it will design and solve very simple circuits. But it will contain the germ of many ideas and you will be or you should be extended to do more complicated things, even things which might be professionally useful. So, let me just talk a little bit about the circuits that we are considering.

(Refer Slide Time: 2:05)

Circuits that we consider

A circuit is made of **components** connected to each other at **nodes**.

- Black disks: nodes
- Components: current sources and resistors.
- Each component is connected between two nodes.

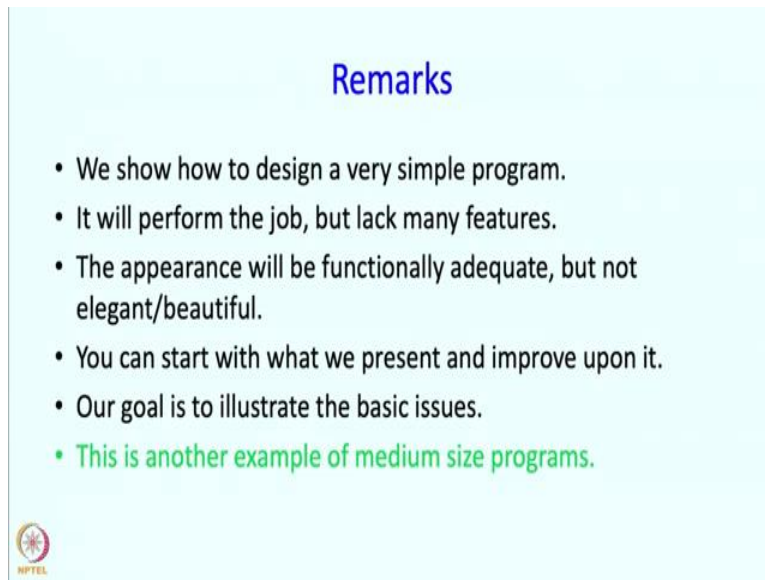

Solving a circuit: determining voltages at nodes and currents through the resistors

So, circuit is made of components connected to each other at nodes. Here, is an example. So, in this example, these black disks, so by that I mean these things, this one, this one, this one are called nodes or we will call these nodes. And, components are current sources or resistors. So, for example this is a resistor, this is another resistor, this is what is called a current source. So, you can have many many other kinds of components, but as we said this is a baby program and we are only going to consider these 2 components. Each component is connected between 2 nodes, as you can see voltage sources, current sources are connected. So, between these two nodes we have a resistor and also a current source and between these two nodes we have this resistor and so on.

And, when we say solving a circuit, what we mean is determining the voltages at the different nodes. So, because current is flowing through these components, it will produce voltages or potentials at, at the nodes. And it will and of course there is a question of how much current is flowing through each of this resistors, or other components that may be there in the circuit. So, when we say let us solve this circuit, we mean figure out what are the current and voltages in it.

(Refer Slide Time: 03:42)

The slide has a light blue background. At the top center, the word "Remarks" is written in a blue, sans-serif font. Below it, a list of six bullet points is displayed. The first five are in black, and the sixth is in green. The NPTEL logo, which consists of a circular emblem with a stylized 'N' and the text "NPTEL" below it, is located in the bottom left corner of the slide.

Remarks

- We show how to design a very simple program.
- It will perform the job, but lack many features.
- The appearance will be functionally adequate, but not elegant/beautiful.
- You can start with what we present and improve upon it.
- Our goal is to illustrate the basic issues.
- This is another example of medium size programs.

So, our program is going to be quite simple, very simplistic in fact, and it will perform the job that I have described but it will lack many features. The appearance will be functionally adequate, but it will not be elegant or beautiful. It will not draw for example the circuit the way you just saw it, it will be a little bit more schematic, and again the point is to get started and the main ideas will be there and you will be able to build upon them if you wish.

Yeah, so you can start with what we present and improve upon it. And, our goal is to illustrate the basics issues. And, I also want to mention that this is going to be another example of medium size programs. So, as we write it you will get another example of how medium size programs have to be organised. So, here is what we are going to do. I am immediately going to start off with demo of our program.

(Refer Slide Time: 04:50)

Outline

Demo of our program

- Use the program to design a simple circuit
- Use the program to solve the designed circuit

Design of the program

- The main loop
- The major data structures
- How the functionality is divided between the data structures
 - Another example of designing medium size programs

So, so I have written the program and I will show it to you and then we will see, I will lead you towards its design. Yeah, so in the demo we will actually use the program to design a very simple circuit. And we will use the program to solve the circuit that we designed. Then we will talk about the design of the program. So, the program will consist of a main loop, and then it will have some data structures and we will discuss how the functionality is divided between the data structures and the main program. And as I said, the organization will follow certain the general principles that we have been talking about as far as designing medium size programs is concerned.

(Refer Slide Time: 05:43)

What we discussed

- CAD, Computer aided design is an important application of computers
- Computer based design programs often use graphical user interfaces
- We will design a baby CAD program for designing and solving resistive circuits.

Next: Demo of the program

So what have we discussed so far? So we have said that CAD or Computer aided design is an important application of computers. Computer based design programs often use graphical user interfaces because these are very convenient, you see what you are doing and pictorially seeing something is very convenient and it tells you exactly what is going on in a very nice way. We are going to design a baby CAD program which will be useful for designing and solving resistive circuits in particular circuits which contain resistors and current sources. And next, I am going to show you a demo of the program but before that let us take a quick break.
