Indian Institute of Technology, Bombay

Lecture – 06
Layered Nature of a Network

(Refer Slide Time: 00:31)

The slide features a blue header with the title "Layered Nature of Networks" and a network diagram. Below the header, there are two bullet points: "Network has multiple layers" and "Each layer has its own functions". A video inset shows Prof. Sridhar Iyer speaking. The footer of the slide reads "Demystifying Networking | CS75".

- Network has multiple layers
- Each layer has its own functions

So now, when we move from the analogy to the network, we see that there is a concept of layering. Just as in the analogy we had the manager and then we had the dispatch section and then we had the packaging section, in a network again there are multiple layers each layer has its own functions.

(Refer Slide Time: 00:42)

Why do we need layers?

- Without layers, each application would have to do all packaging, dispatching etc by itself.
 - This is suitable for 1-time activity on a 'small' scale.
 - Not suitable When there is re-use or multiple choices

Demystifying Networking | CS75

So, before we get into that, let us ask the question why do we need these layers? what does it give us? So, the key point here is that it can be done without having layers also; however, in that case every application. For example: you might think of a web service application; let us say, you are using your web server to get information from a client or you might think of a file transfer application, where you are moving files across the network. So, each application would have to do the entire packaging and the entire dispatching operations by itself.

(Refer Slide Time: 01:16)

Layered Nature of Networks

An example for separation of concerns:

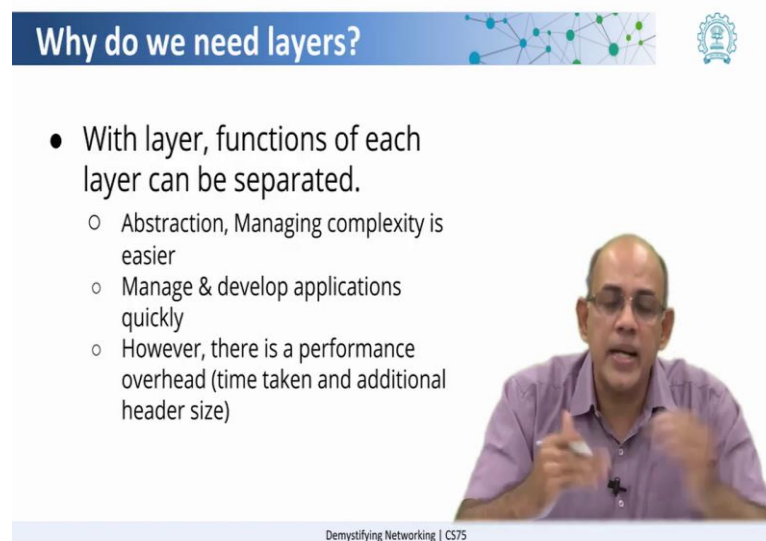

| Layer | Function |
|-------------|---|
| Application | Talks to application layer on other side to provide services |
| Transport | Ensuring that packets are sent and received in correct sequence |
| Dispatch | Ensures that packet goes along the desired route |

Demystifying Networking | CS75

In order to avoid that, what we do in networks is to provide this idea of layers, so that the functions can be separated. So, the application layer now only worries about talking to the corresponding application layer on the other side of the network. The transport layer worries only about ensuring that packets are sent in the correct sequence and are received in the correct sequence. The dispatch layer worries only about making sure that the packet goes along the desired route.

(Refer Slide Time: 01:48)

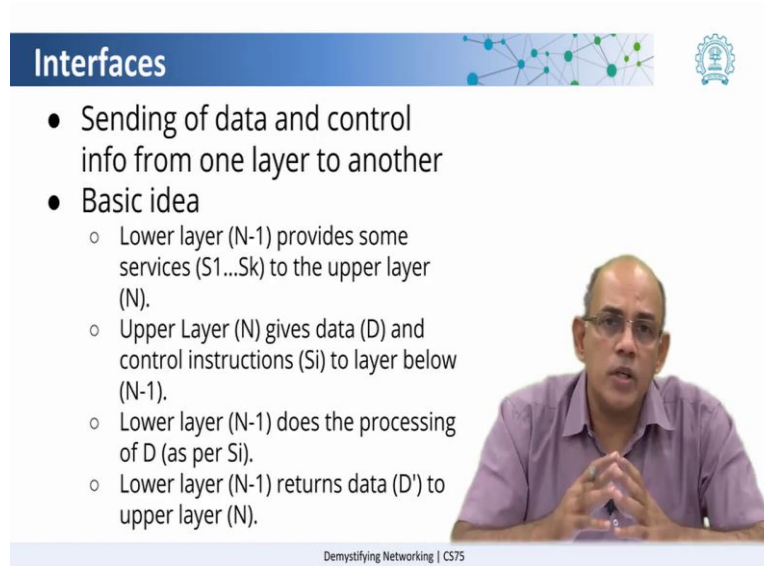

Why do we need layers?

- With layer, functions of each layer can be separated.
 - Abstraction, Managing complexity is easier
 - Manage & develop applications quickly
 - However, there is a performance overhead (time taken and additional header size)

Demystifying Networking | CS75

So, by separating these concerns it becomes easier to manage the applications as well as to develop applications quickly.

(Refer Slide Time: 02:00)

Interfaces

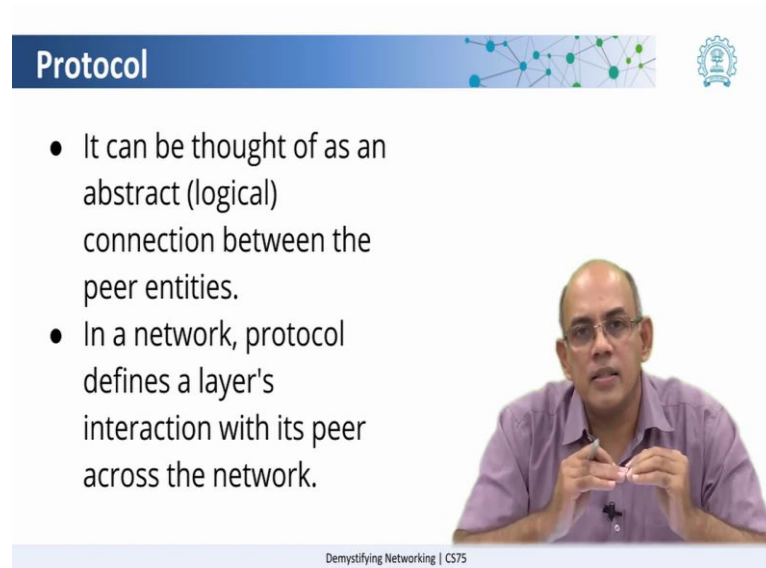

- Sending of data and control info from one layer to another
- Basic idea
 - Lower layer (N-1) provides some services (S1...Sk) to the upper layer (N).
 - Upper Layer (N) gives data (D) and control instructions (Si) to layer below (N-1).
 - Lower layer (N-1) does the processing of D (as per Si).
 - Lower layer (N-1) returns data (D') to upper layer (N).

Demystifying Networking | CS75

Now, how do these layers work? The basic idea is that each layer provides a service to the layer above and it utilises the services of the layer below. For example, the application layer gives some data and some address to the transport layer. Now, this information is the transport layer's responsibility to communicate from one end of the network to the other end of the network. At the other end again this information is reassembled and sent back to the application layer.

So when you make a web request, what happens is your request is packaged and sent across the network at the web server side, the request is again received in the original form by the web server. So, each layer provides a service to the layer above it, through what is called the interface. The interface is nothing, but sending of the data and some control information from one layer to the other.

(Refer Slide Time: 03:11)

Protocol

- It can be thought of as an abstract (logical) connection between the peer entities.
- In a network, protocol defines a layer's interaction with its peer across the network.

Demystifying Networking | CS75

Now, along with layers there is the concept of protocols. What is a protocol? Protocol is nothing, but an understanding between two entities of how they are going to communicate. So, there are various protocols.

In the networking world, the protocol means that a layer on the client side is communicating with the corresponding layer on the server side. For example, when the transport layer which is responsible for creating the packets and numbering them and keeping track of them is communicating with the peer layer, the transport layer on the other side of the network, they need the notion of acknowledgements.

(Refer Slide Time: 03:52)

Protocol

- This is required to exchange control information, keeping track of communication etc
- It is an agreement on:
 - Interpretation of data: Syntax and Semantics.
 - Sequence of control flow: Request and Response.

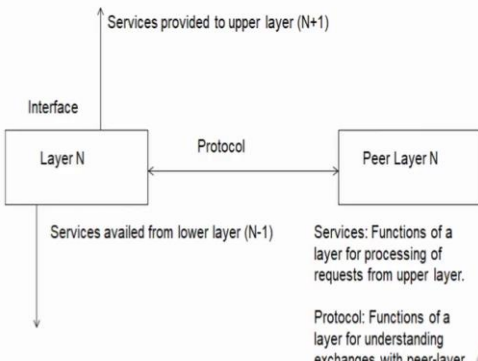

Demystifying Networking | CS75

So that the layer can keep track of which packets have been received on the other side, which acknowledgements have come, which packets may have been lost, which need to be retransmitted and so on. So, in order to have these understanding between the same layer across the network that idea is called a protocol. So, they have a mechanism by which certain control packets are exchanged by which they come to know, what is the current state of the data that is being transmitted across the network.

(Refer Slide Time: 04:27)

Layered Nature of Network

The diagram illustrates the layered nature of a network. It shows a central box labeled 'Layer N' connected to a box labeled 'Peer Layer N' by a double-headed arrow labeled 'Protocol'. Above 'Layer N', an arrow labeled 'Interface' points to 'Services provided to upper layer (N+1)'. Below 'Layer N', an arrow points to 'Services availed from lower layer (N-1)'. To the right of the diagram, there are two text blocks: 'Services: Functions of a layer for processing of requests from upper layer.' and 'Protocol: Functions of a layer for understanding exchanges with peer-layer.'

Demystifying Networking | CS75

To summarize the concept of layering involves two ideas. One is the idea of interfaces through which one layer is able to talk to the layer below it and pass on the data and control information. And, the other idea is that of the protocol, wherein one layer is able to talk its peer at the other end of the network. So, both of these have a notion of some syntax, which is how is the packet to be framed, what should be the control signals and so on. And some semantics, which is, how should these signals be interpreted.
