

Demystifying Networking
Prof. Sridhar Iyer
Department of Computer Science and Engineering
Indian Institute of Technology, Bombay

Lecture - 68
Summary of the entire TCP IP stack

Now, that we have seen the details of communication and protocols at different layers. Let us begin within a reflection spot.

(Refer Slide Time: 00:11)

The slide features a header with the text "Reflection Spot" in white on an orange background. To the right of the header is a network diagram with blue and green nodes connected by lines, and a small circular logo of the Indian Institute of Technology. The main content consists of three paragraphs of text in a light blue font. The first paragraph states: "We have an application on client system which wants to communicate to server." The second paragraph asks: "Can you trace a path that the request packet from the client will take, down the layers on client's system, across the network, then up the layers on the server and then back." The third paragraph says: "Also think about all the processing that happens on the network." Below the text is a pink rectangular box containing the instructions: "Pause the Video", "Note down your solution", and "Then play the video". At the bottom of the slide, there is a footer in a light orange bar that reads "Demystifying Networking | CS75".

Suppose we have an application on a client which wants to communicate with corresponding application on the server. Can you trace out the path that the packet will take the request packet will take all the way, down the chain on the client side across the network and up the chain of the server side. Take a moment to think about what all steps of processing happen to this packet at the different layers and then proceed.

Reflection Spot

The different layers that are used in the process

				DATA
			Port Numbers	DATA

Application Layer

Source Port

Destination Port

Demystifying Networking | CS75

The slide features a presenter in a light purple shirt on the right side, gesturing with his hands. The background is white with an orange header bar and a network diagram icon.

Many of you may have thought about the different layers that are coming in the process.

So, some of them for example, the request is generated by the application. What is the corresponding information that the application layer provides? It provides the source and the destination, right, you know the source, you know the source port, you know the destination and you know the designation port. For example, if it is your browser which is making an application request to search engine, you know the source port which is HTTP and you know the destination which is the web server.

(Refer Slide Time: 01:27)

The different layers that are used in the process

					DATA
				Port Numbers	DATA
			Seq. Number	Port Numbers	DATA
	IP Address	Seq. Number	Port Numbers	Port Numbers	DATA
MAC Address	IP Address	Seq. Number	Port Numbers	Port Numbers	DATA

Demystifying Networking | CS75

The slide features a presenter in a light purple shirt on the right side, looking at the camera. The background is white with an orange header bar and a network diagram icon.

And then at the next level the domain names are translated into IP address by a domain name look up followed by adding the IP addresses into the packet. So, you can think of the packet as how it grows along. So, it starts with just the data, then there is the application ports, then there is the IP addresses which are attached and then there are sequence numbers which are attached and once it comes down to the MAC level, the MAC address is also updated at every routing point. On arrival at the destination, it is like opening a bunch of envelop. So, you keep opening these envelops till you get to the data and the data is passed over to the application layer.

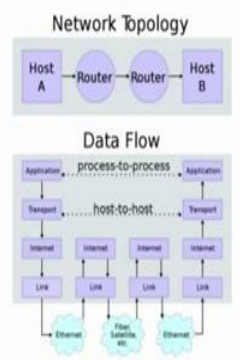

(Refer Slide Time: 02:07)

To look at this in slightly more detail, let us look at this slide where we see the data packet and we see all these headers that I talked about being attached at each of the layers.

(Refer Slide Time: 02:21)

Layer by Layer Communication

Network Topology

Host A → Router → Router → Host B

Data Flow

Application (process-to-process) → Transport (host-to-host) → Internet → Link → Ethernet, Fiber, Satellite, etc.

The application on each host executes read and write operations as if the processes were directly connected to each other by some kind of data pipe. After establishment of this pipe, most details of the communication are hidden from each process, as the underlying principles of communication are implemented in the lower protocol layers.

Demystifying Networking | CS75

Let us start with the top layer. There is host a there are a couple of routers in the on the way and then there is host B which need to communicate with each other. Now, at each layer, it appears that the layer is communicating with its peer entity at the other side, whereas, actually the packet is going down the network coming up into the routers going back down and then coming up at the other end.

(Refer Slide Time: 02:45)

Layer by Layer Communication

Network Topology

Host A → Router → Router → Host B

Data Flow

Application (process-to-process) → Transport (host-to-host) → Internet → Link → Ethernet, Fiber, Satellite, etc.

On the transport layer the communication appears as host-to-host, without knowledge of the application data structures and the connecting routers,

While at the internetworking layer, individual network boundaries are traversed at each router.

(Refer Slide Time: 02:49)

Layer by Layer Communication

Network Topology

Data Flow

Request is generated by an Application with a Source and destination port for the application or service.

The protocol for communication is determined and control information is added.

The source and destination IP addresses are added.

Based on the destination IP address the MAC address for the next hop is added. MAC address is updated as per routing table based on the destination IP level (through the next hop).

Demystifying Networking | CS75

So, for example when the request is generated by the application with the source and destination port, it appears that the application layer is communicating with the application layer at the other end. So, it is a process to process communication.

(Refer Slide Time: 03:01)

Layer by Layer Communication

Network Topology

Data Flow

The protocol for communication is determined and control information is added.

The source and destination IP addresses are added.

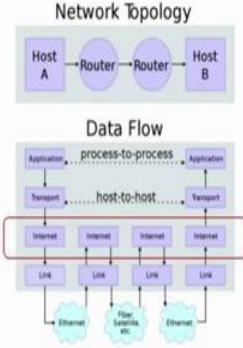

Based on the destination IP address the MAC address for the next hop is added. MAC address is updated as per routing table based on the destination IP level (through the next hop).

Demystifying Networking | CS75

Then when the protocol for communication is determined, the corresponding control information is added. For example, if the protocol is TCP, then there are corresponding TCP ports which are opened, TCP sequence numbers which are decided and so on. So, this now from instead of process to process communication becomes a host to host communication because some packet from one machine are now to be taken to another machine.

(Refer Slide Time: 03:31)

Layer by Layer Communication

The diagram illustrates network communication layers. The 'Network Topology' shows Host A connected to two Routers, which are then connected to Host B. The 'Data Flow' diagram shows the flow from Application (process-to-process) to Transport (host-to-host) to Internet (IP) to Link (Ethernet, Fiber, etc.). A red box highlights the Internet and Link layers.

The source and destination IP addresses are added

Based on the destination IP address the MAC address for the next hop is added. MAC address is updated at every routing point based on the destination IP and IP address is updated at NAT points.

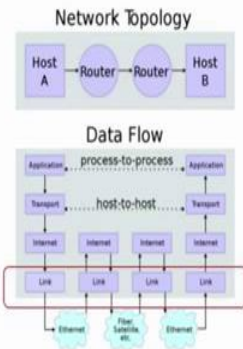

By en:User:Kbrose - Prior Wikipedia artwork by en:User:Cburnett, CC BY-SA 3.0, <https://commons.wikimedia.org/w/index.php/>

Demystifying Networking | CS75

One level lower than that are the source and destination IP addresses which are attached, this becomes a network level communication, because now the packet is free to go in different routes, different packets can take different routes from one host to the other from A to B and they will be reassembled at B.

(Refer Slide Time: 03:53)

Layer by Layer Communication

The diagram illustrates network communication layers. The 'Network Topology' shows Host A connected to two Routers, which are then connected to Host B. The 'Data Flow' diagram shows the flow from Application (process-to-process) to Transport (host-to-host) to Internet (IP) to Link (Ethernet, Fiber, etc.). A red box highlights the Internet and Link layers.

Based on the destination IP address the MAC address for the next hop is added. MAC address is updated at every routing point based on the destination IP and IP address is updated at NAT points.

Demystifying Networking | CS75

Finally, in order to put the packet on to the link based on the destination IP address, the corresponding MAC address for the next hop is added. And now the interesting thing to note is this MAC address is the one which changes most frequently because it every hop,

the MAC address of the next link has to be changed. How often does the IP address change? The IP address does not change because you are going to a single host destination, right, and how often does the application port number change, the application port number also does not change because on that destination, the transport layer knows which application it has to hand over the packet to. So, this is the broad idea by which the data flows through the network.

(Refer Slide Time: 04:43)

Layer by Layer Communication

Network Topology

Host A → Router → Router → Host B

Data Flow

Application (process-to-process) → Transport (host-to-host) → Internet → Link (Ethernet, Fiber, Satellite)

On arrival at the destination based on the port address the application opens the request and send the response by switching the Source and destination ports, IPs and the packet travels down the layers again.

By en User Kbrose - Prior Wikipedia artwork by en User Cburnett, CC BY-SA 3.0, https://commons.wikimedia.org/wiki/File:Layer_by_Layer_Communication.png

Demystifying Networking | CS75

So, on arrival at the destination, based on the port address, the application opens the request and sends the response. How does this response go? It takes a similar path, as far as the network is concerned, it does not differentiate between a request and a response, it treats both of them as packets. And it does exactly the same thing - it attaches IP addresses, it attaches port numbers and it attaches the headers of the MAC addresses and so on and the packet travels back from the destination back to the source as a reply packet.

So, this broadly summarizes how communication happens in today's computer networks. Now, that you have a complete picture of how communication happens over the internet, it is time to complete the assignment for this week, have fun.
