Lecture - 10
The Completeness Theorem

Today we will do an important theorem called the Completeness Theorem. Which, you will see some of the consequences of compactness and it something that this compactness is actually very closely related to that topological notion of compactness. And it is possible to say it, possible that it is possible to show that this, compactness is really the same as the topological notion of compactness either, defined through matrix spaces or through neighborhood spaces whatever. So, this compactness theorem but we will look again independent of topology we will just look at it as a in it is isolation.

Satisfiability of Infinite Sets

From corollaries 9.4 and 9.5 we have

Corollary 10.1 *A finite set Γ is unsatisfiable iff there is a closed tableau rooted at Γ .*

■

Corollary 10.2 *If a finite set Γ is satisfiable then every nonempty subset of Γ is satisfiable too.*

■

Question 1. Suppose Γ were a denumerable (countably infinite) set. Under what conditions is Γ satisfiable?

Question 2. Suppose every subset of a denumerable set Γ is satisfiable. Then is Γ necessarily satisfiable?

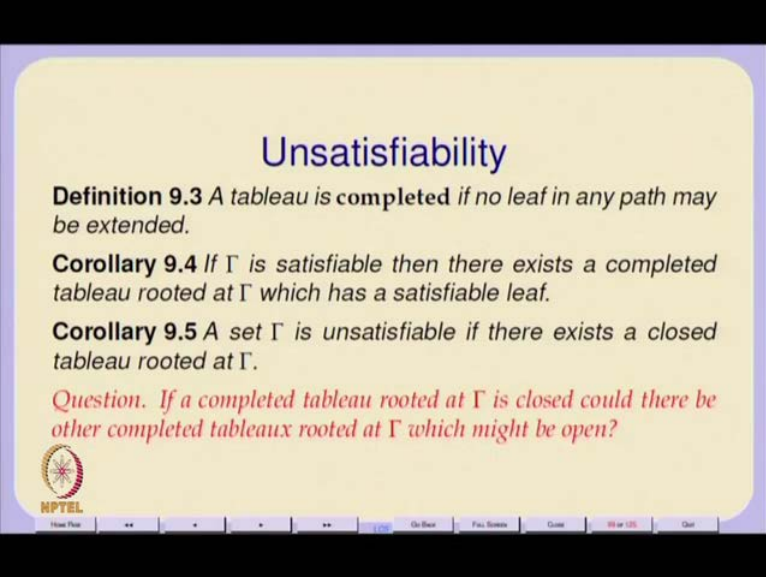

Question 3. Suppose that only all finite subsets of a denumerable set are satisfiable. Then is Γ satisfiable?

Navigation icons: Home, Prev, Next, First, Last, Find, etc.

And so and it is we will see the importance of that. So, main thing is what does supposing you have an infinite set of sentences. And you want to know essentially by infinite of course we are talking about a logical system it is we mean only countably infinite. So, denumerable we are looking at denumerable sets of sentences and essentially if, you look at this Satisfiability of Infinite Sets say essentially from these corollaries 9.4 and 9.5 which essentially says that.

So now, when you are talking about infinite sets there is no guarantee that your tableau construction would be finite. So but, we can always take the notion of that tableau to infinite a tableau is just a tree. We take the notion to infinite trees that is as simple as that .

(Refer Slide Time: 02:17)

Unsatisfiability

Definition 9.3 *A tableau is completed if no leaf in any path may be extended.*

Corollary 9.4 *If Γ is satisfiable then there exists a completed tableau rooted at Γ which has a satisfiable leaf.*

Corollary 9.5 *A set Γ is unsatisfiable if there exists a closed tableau rooted at Γ .*

Question. If a completed tableau rooted at Γ is closed could there be other completed tableaux rooted at Γ which might be open?

NPTEL

Navigation icons: Home, Back, Forward, Search, etc.

So, this corollaries 9.4 and 9.5 say that. if gamma is satisfiable then there exists a completed tableau rooted at gamma which has a satisfiable leaf. And a set gamma is unsatisfiable if there exists a closed tableau rooted at gamma but, a the corresponding notion for infinite sets would be that. If, an infinite set is unsatisfiable then you should definitely get a closed tableau or there should be at least one closed tableau. But, if it is satisfiable then there would be essentially be some kind of infinite tree but the problem with any finite point of that infinite tree is you do not know whether it is going to close at a later point .

So, there is a problem when dealing with these issues for infinite sets. And so what we would like to do is we would like to look at this notion of satisfiability of infinite sets. And satisfiability as far as we are concerned is the same thing as consistency of an infinite set of sentences . So, essentially so these are the questions that it raises suppose gamma were a denumerable set under what conditions is gamma satisfiable. Suppose every subset of a denumerable set gamma is satisfiable then, can you say whether gamma is necessarily satisfiable.

So whole point about dealing with any kind of infinity is to either get a finite representation or to get approximation in terms of finite tree objects.

So, the construction of let us say irrational numbers or real numbers by deleting cuts is essentially as looking at finite tree intervals or at least intervals with end points and trying to represent let us say real numbers as limits of those. So, limits and continuity are the most important notions when it comes to infinite sets in any branch of mathematics here. So one question is whether you can always approximate something infinite by a possible infinite set of finite tree approximations. So that this infinite tree set each approximation is finite tree but, the set itself might be infinite so essentially you have some limit construction which tells you that if this limit exists then so it is then this infinite tree object is essentially being captured.

And that is exactly what has been happening throughout the history of mathematics ever since the start of the subject of analysis. So, this question to essentially is asking whether this infinite tree object this infinite set of sentences its satisfiability can somehow be expressed in terms of finite tree approximations satisfiability of finite subsets. Then, of course the converse question is that is related to the topological notion of continuity and limit does a limit exist sometimes under discontinuity those limits do not exist. So here, suppose only finite subsets of a denumerable set γ are satisfiable then what can you say about the satisfiability of the whole of γ that is.

So, these are the kind of questions that actually come up when you have in any branch of mathematics when you have some infinite tree object. And this also includes all branches related to mathematics like this also happens in the case of trying to find the semantics of recursion in programming languages for example. So, it has a wide kind of applicability the kinds of methods that are used have a wide kind of applicability.

Trees & König's Lemma

Consider **trees** which may be either finite or infinite.

Definition 10.3 Let $\mathcal{T} = \langle N, \rightarrow, r \rangle$ be a tree rooted at node $r \in N$. A node $n \in N$ is called **infinitary** if $\text{Desc}(n)$ is an infinite set otherwise it is called **finitary**.

Lemma 10.4 In a finitely branching tree, every infinitary node has an infinitary successor. □

Lemma 10.5 König's Lemma Every finitely branching infinite tree has an infinite path. □

 NPTEL

Handout | ** | * | ** | Home | File System | Close | 10 of 15 | Quit

So now, we have to consider trees in some generality. We have to be prepared to deal with infinite trees throughout our data structures and algorithms kinds of course trees are always finite. But now, for example you have actually come across infinite trees when you do define this SOS semantics of a programming language with values what an SOS semantics generates for a program is for the dynamic behavior of the program is essentially an infinite tree. And so the program itself is a finite object that is a finite abstract in text tree but, the behavior of the program the execution behavior of the program is essentially infinite tree. So, we let us look at trees and let us also specify some of our notation and terms.

(Refer Slide Time: 07:36)

Rooted trees: Definitions and facts

Definition 10.6

- An **unordered tree** is a pair $\langle N, \rightarrow \rangle$ consisting of a finite or a countably infinite set N of nodes and a set $\rightarrow \subseteq N \times N$ of **(directed) edges** such that for any edge $(s, t) \in \rightarrow$ (usually denoted $s \rightarrow t$ in infix notation), s is called the **source** and t the **target** of the edge. s is called a **predecessor** of t and t is called a **successor** of s .
- A **(rooted) tree** is a triple $\langle N, \rightarrow, r \rangle$ such that $\langle N, \rightarrow \rangle$ is an unordered tree and $r \in N$ is a distinguished node called the **root** of the tree and satisfying the following the properties.
 - There exists a function $\ell : N \rightarrow \mathbb{N}$ called the **level** such that $\ell(r) = 0$ and for any $s \rightarrow t$, $\ell(t) = \ell(s) + 1$.
 - Every node in $N - \{r\}$ has a **unique predecessor**.

We will be primarily interested in rooted trees and we will simply refer to them as trees.

Facts 10.7

Every node in N is source or a target of one or more edges.

So, we are interested really in not un ordered trees where so Iam distinguishing between un ordered trees and rooted trees. Unordered trees are that kinds of trees you get in graph theory which, is not necessarily the same as the kinds of trees you get in let us say structures and algorithms so all the trees that we deal with in computer science usually are rooted trees. So, our abstract in text trees are rooted trees execution behavior of programs are all rooted trees they start from a starting point and then more over all the edges in these trees are all directed edges and they are not undirected edges. So, we will look at a rooted tree.

So, a rooted tree essentially consists of a set of nodes end and an edge relation which I will represent by an arrow. And of course it distinguished node called the root such that of course every note other than the root has some what might be called a unique predecessor. And there exists a function called the level function which for the root gives you a 0. And for any given an edge from s to t where s and t are both nodes then the level of t is one more than the level of s . So, this ensures I mean these things are fact that l is function, and the fact that you have an exact notion of successor here and a predecessor here essentially make it clear that. This rooted tree is for example a cyclic and it does not have any self loops nodes do not have self loops.

And then this function essentially guarantees that the nodes are not sort of repeated here so, there you cannot have multiple copies of nodes. So, it is like the standard notion of trees that you

encounter in data structures in algorithms like binary trees and so on so forth. And of course, only difference here is that this set N could be infinite so, you can have a tree with an infinite set of nodes it need not be finite. Otherwise it is a standard set of standard notion of a binary tree or a multi way tree that we have.

(Refer Slide Time: 10:11)

- The \rightarrow relation is irreflexive (i.e. there is no edge whose source and target are the same node).
- The root node has no predecessor.
- A leaf (node) is a node with no successor.

Definition 10.8 Let $\mathcal{T} = (N, \rightarrow, r)$ be a rooted tree.

- \mathcal{T} is also called a tree rooted at r .
- \mathcal{T} is infinite if N is an infinite set.
- A path in \mathcal{T} is a finite or (countably) infinite sequence $r = n_0 \rightarrow n_1 \rightarrow n_2 \rightarrow \dots$ such that $(n_i, n_{i+1}) \in \rightarrow$ for each $i \geq 0$.
- A finite path $r = n_0 \rightarrow n_1 \rightarrow n_2 \rightarrow \dots n_m$ is said to have a length $m \geq 0$. A path which is not finite is said to be infinite.
- A branch is a maximal path – it is either infinite or is finite $r = n_0 \rightarrow n_1 \rightarrow n_2 \rightarrow \dots n_m$ such that n_m is a leaf.

- The successors of a node $s \in N$ is the set $\text{Succ}(s) = \{t \in N \mid s \rightarrow t\}$ and predecessors of a node $t \in N$ is the set $\text{Pred}(t) = \{s \in N \mid s \rightarrow t\}$.

NPTEL

So, the basic facts are that so this edge relation is irreflexive and the root has no predecessor and there is a notion of a leaf node which are in the case of finite in the case where trees are finite there is a the leaf nodes do not have successive that is. So, we also talk about trees rooted at some r and the usual notion of a path in this case we define a path as always starting from the root here. If, it is does not start from the root we can talk about a segment of the path or we can talk about a path starting from a the root of a sub tree rooted at some node and so on so forth.

But, otherwise in general when we talk about a path we will just talk about a path starting root so essentially you traverse the arrows you traverse the nodes so that each you go through successor nodes some sequence of successor nodes. So, since our trees can be infinite so your path can also be finite or infinite. And we will talk about branch as a maximal path so, it means you do not start any where you do not stop any where you go through the full path from the starting from the root. And then we have this usual notions like successor of a node predecessor's of a node.

(Refer Slide Time: 11:41)

• \rightarrow^* is the transitive closure of the \rightarrow relation and \rightarrow^+ is the reflexive-transitive closure of \rightarrow .

• The **descendants** of a node $n \in N$ is the set $\text{Desc}(n) = \{n\} \cup \bigcup_{s \in \text{Succ}(n)} \text{Desc}(s)$ and $\text{Desc}(n) - \{n\}$ is the set of **proper descendants** of n .

• The **ancestors** of a node n is the set $\text{Ances}(n) = \{n\} \cup \bigcup_{s \in \text{Pred}(n)} \text{Ances}(s)$ and the **proper ancestors** of n is the set $\text{Ances}(n) - \{n\}$.

• A **subtree** of a rooted tree $\mathcal{T} = \langle N, \rightarrow, r \rangle$ is a tree $\mathcal{T}' = \langle \text{Desc}(n), \rightarrow', n \rangle$ rooted at a node $n \in \text{Desc}(r)$ such that $s \rightarrow' t$ for $s, t \in \text{Desc}(n)$ if and only if $s \rightarrow t$.

• A rooted tree $\mathcal{T} = \langle N, \rightarrow, r \rangle$ may be **extended** to another tree $\mathcal{T}' = \langle N', \rightarrow', r \rangle$ by an edge $n \rightarrow' n'$ provided $n' \notin N$, $N' = N \cup \{n'\}$ and n is a leaf node of \mathcal{T} .

• $\mathcal{T} = \langle N, \rightarrow, r \rangle$ is said to be **finitely branching** if for each $n \in N$, $\text{Succ}(n)$ is a finite set.

Facts 10.9 In any rooted tree $\mathcal{T} = \langle N, \rightarrow, r \rangle$,

1. $N = \text{Desc}(r)$

$\text{Ances}(n) = \{s \in N \mid s \rightarrow^* n\}$ for any $n \in N$.

NPTEL

And since this arrow the edge relation is irreflexive we can consider the transitive closure of the edge relation. We can consider the reflexive transitive closure of the edge relations those will just be represented as arrow plus and arrow star respectively. And you can talk about the descendants of a node which I will represent by Desc. We can talk about ancestors of a node and of course, the root node has no ancestors we can talk about sub trees rooted at some node and we can also talk about tree being extended at the leaves to another tree.

So, what I have in particular I have said that when we talk about a tree we are talking about this edge relation in such a way where that tree is well in graph theoretic terms it is weakly connected. So, there are no isolated nodes there are no sub trees disconnected from other sub trees and so on and so forth. So, I have so a sub tree rooted at a node also means that we are essentially restricting the set of nodes from n to all the descendants of that node n . So, that is why the sub tree t prime here that is why so I can take a sub T I can take the tree rooted at r and I can take a tree t prime rooted at some node in t . And just look at all its descendants so and then there is essentially a new edge relation arrow prime. This arrow prime is just a subset of the old arrow relation the edge relation except that it is restricted to only the descendants of n . So, by the way my definition of descendants includes n also so there is a I made it reflexive and similarly for ancestors also I have made it reflexive.

So, this is the notion of a sub tree rooted at something then, we can also talk about extending the tree with a new node such that the new tree has the same root as old tree. So it is the distinguished root is still the same except that there is an extra edge for a new node n' which was not there in the original set of nodes. So, you are the new set of nodes N' is just the old set of nodes n union the new n' . So, you can extend it one leaf at a time so and this is an extension that i have tableau construction naturally allows so this is a way. And finally we will say that a tree is finitely branching. So now, when you talk about infinite trees there is possibility that you might have an infinite number of branches you might have an unbounded number of branches but finite and you might have infinite paths also.

So, we can talk about trees being finitely branching. If, every node has only a finite set of successors immediate successors here then we will say that the tree is finitely branching. So the tree could be infinite and a finitely branching tree could still have an infinite number of paths. So, in that sense the number of different branches could be infinite paths could be of infinite length, the number of different branches could be infinite. But, any particular node has only a finite number of immediate successors and so that is it is important the other thing of course is that something that I did not mention but which we will take for granted is that this set of nodes n can be at most countably infinite. I mean we are not taking set of nodes which might be uncountable or anything.

So, it could be only countably infinite set of nodes. But, then even though the tree is finitely branching it could actually have a infinite number of different paths distinct paths each it could have both finite and infinite length paths branches. And so those we are not putting any restrictions on that. So, one thing of course these are some simple facts as a consequence of these definitions if the for any tree rooted at r the descendants of r are exactly the set n set of nodes ancestors and so on.

(Refer Slide Time: 16:57)

3. $\text{Desc}(n) = \{t \in N \mid n \rightarrow^* t\}$ for any $n \in N$.

4. A rooted tree is acyclic i.e. for all nodes $n, n \not\rightarrow^* n$.

Definition 10.10 Let $\mathcal{T} = (N, \rightarrow, r)$ be a tree rooted at node $r \in N$. A node $n \in N$ is called **infinitary** if $\text{Desc}(n)$ is an infinite set otherwise it is called **finitary**.

Lemma 10.11 In a finitely branching tree, every infinitary node has an infinitary successor.

Proof: If not, then for some infinitary node n , $\text{Succ}(n)$ is finite and for each $s \in \text{Succ}(n)$, $\text{Desc}(s)$ is finite which implies $\text{Desc}(n) = \{n\} \cup \bigcup_{s \in \text{Succ}(n)} \text{Desc}(s)$ a finite union of finite sets would be finite.

Lemma 10.12 (König's Lemma) Every finitely branching infinite tree has an infinite path.

Proof: Assume $\mathcal{T} = (N, \rightarrow, r)$ is a finitely branching infinite rooted tree which has no infinite path. Clearly since $N = \bigcup_{n \in N} \text{Desc}(n)$ is infinite, r is infinitary. r has an infinitary successor by lemma 10.11. Hence there exists a maximal path in \mathcal{T} all of whose nodes are infinitary. This path has to be infinite, otherwise there would be a last node in the path which is finitary but has no successors, which is impossible. ■

NPTEL

And these are I mean these are usual

things and then a rooted tree is usually a cyclic and basically for all nodes there is no path of length one or more from a node tree itself. So, it is that is the basically condition so the notion of self loop is something we eliminated at the start because, we said that l of t is equal to l of s plus 1. And that is not possible unless I mean unless you exclude self loops. But now, we have to this also consequence of all that is also that trees have to be basically. The other thing is we will take so, we will let us take any tree and we will call a node to be infinite tree if the set of descendants of that node is an infinite set. So, a descendants means you are taking all possible finite length paths starting from that node. All possible so descendants is synonymous with this reflexive transitive closure of the edge relation so this reflexive transitive closure does not go through infinite path infinite length paths it only looks at all finite length paths that is important.

So, the a node is called infinite tree if all its descendant if the set of its descendant's is infinite otherwise the node is called finite tree. But, still so a finitely branching tree could have infinite tree nodes. So all that we are saying is that for any node its the set of its immediate successor's is a finite set. But, the set of its descendants need not be finite. So, nodes could be infinite so one basic one simple Lemma that we have is in a finitely branching tree every infinite tree node has an infinite tree successor. You can think of this the next two these two lemma as essentially some kind of pigeon hole principle generalized to infinite trees. Means the analogy with pigeon holes is let us look at the standard pigeon hole principle. It is usually defined for finite sets and you

essentially say if there are n plus one elements n plus one balls to be distributed in n boxes. Then, there is at least one box which has two balls.

You can start generalizing this for all kinds of finite ends and n plus all kinds of ends so on and so forth. But, you can also go into an n infinite set if I have an infinite collection of balls and I have a finite number n of boxes. Then, an extended pigeon hole principle would essentially say that there is at least one box with an infinite number of balls in it. But, these when you look at so finitely branching trees are a further weakening of that because even though a tree might be finitely branching. The number of different branches might still be infinite. So, actually you have so the branches corresponding to the infinite boxes and think of putting the individual nodes in the individual boxes distributing the nodes in the boxes. So it is a kind of infinite tree pigeon hole principle for finitely branching trees.

So, in a finitely branching tree so what we are saying this every infinite tree node has an infinite tree successor is essentially like saying that there is at least one branch. So actually that it becomes more clear with the next lemma which is going to use this lemma every finitely branching infinite tree has an infinite paths and this is Konig's Lemma.

And this essentially says that if I take all these branches as boxes and the nodes as balls. Then, there is at least one box with an infinite number of balls in it. The main weakening here is that a finitely branching tree need not correspond to only a finite number of boxes. It is finitely branching but the total number of distinct branches might be infinite. So, it is still so you are you are looking at a case of an infinite number of balls being put in an infinite number of boxes. But, there is this constraint of finitely branching which somehow seems to indicate that there should be at least one box with an infinite number of balls.

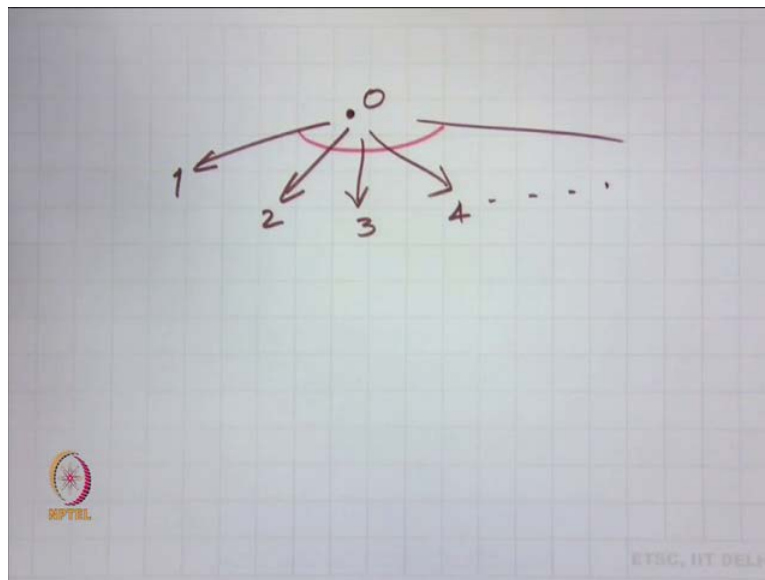

So, let us look at the proof of the first lemma. So, all we are saying is that so we can label the nodes as being each we can associate the finite tree or infinite tree property with each node. And we are saying that you know finitely branching tree every infinite tree node has an infinite tree successor. Supposing not suppose that is not true then for there is some infinite tree node which of course is a finitely branching tree so the successors of that node the set of successor's of that node is a finite set. So which means and if it is if there is an infinite tree node which does not have any infinite tree successor. Then, all the successors are finite tree. If, all the successors are

finite tree then they each of the successors has only a finite number of descendants. And therefore I can actually add up all those sets and I get only a I get that then original node therefore must be finite tree which contradicts assumption that the original node was infinite tree. So, which means that among the successors of this infinite tree node n there is at least one node which is also infinite tree yes is it clear.

So, now let us go to König's Lemma proper which just says that every finitely branching infinite tree has an infinite path. So, again we prove by contradiction assume that t is a finitely branching infinite rooted tree which has no infinite path. Then, firstly the root that descend the set of descendants of the root is entire set of nodes it is an infinite tree. So, the root is clearly infinite tree by the previous lemma the successors of the root there must be one node which is infinite tree at least. So which means that so r is the root node r is infinite tree and r has an infinite tree successor by this previous lemma which means there exists a maximal path end t all of whose nodes are infinite tree. Because, an infinite tree and every infinite tree node is guaranteed to have an infinite tree successor so you take this. So, from r there exists a maximal path in which all of the nodes are infinite tree which means that, path has to be an infinite path.

So, even though the tree might have an infinite number of different paths there is it is not that so the tree can never if it is finitely branching so if the tree is infinitely branching then all paths could be finite. So, for example if I were to right. so for example here is a so you can just take a tree with root node 0 .

(Refer Slide Time: 26:04)

And I can have infinite number of branches basically 1, 2, 3, 4. Say in infinitely branching tree where every path can be finite. Every path has as link of 1 this is an infinitely branching this is an infinite tree which has a single infinity node 0. And all other nodes are a leaf node is finitary cannot be infinite. So, what Quensclimer says is that so now if I have finitely is but unfortunately this thing is in infinitely branching node this node 0 is an infinitely branching node. So, this does not satisfy Quensclimer. If, I made sure that every node has only a finite number of successors and the tree is still infinite. Then, even though there might be an infinite number of different branches there is at least one branch which is an infinite path.

It is actually a beautiful generalization of a pigeonhole principle for finitely branching trees. So, in fact what you can do is so this is actually in the form of an implication. It is actually you can I can reword Quensclimer as every infinite rooted tree is either infinitely branching or is finitely branching and has at least one infinite path. That is your pigeonhole principle for all rooted trees if you like. So, this see it is actually surprising the lemma is very basic but some entity is actually widely known. But, it is never thought usually in any undergraduate course as have you guys uncounted this lemma before is a very simple lemma. But, it is some never someone never people never teach it any undergraduate course. But, it becomes important for the for our notion of compactness

(Refer Slide Time: 28:25)

The Compactness Theorem

Theorem 10.13 (The Compactness Theorem) A (countably) infinite set is satisfiable if all its nonempty finite subsets are satisfiable. □

Corollary 10.14 Any (finite or infinite) set of formulae is satisfiable iff all its non-empty finite subsets are satisfiable.

Note:

- If Γ is a countably infinite set then it can be placed in 1-1 correspondence with the set \mathbb{N} of naturals and hence there is some enumeration of its formulae and each formula carries an unique index from \mathbb{N} .

NPTEL

Home Page ** * ** Go Back Prev Screen Close 11 of 15 Quit

So, which gives us brings us to the compactness things. So, take a countable infinite set a sentence satisfiable. This infinite sentences is satisfiable if all non empty finites sub sets of the set are satisfied. The first thing to realize in this theorem is that any count ably infinite set has an unaccountably infinite number of different sub sets. But, of course out of that uncountable number of different sub sets. The number of finite subsets is only countable all the other sub sets or all infinite sub sets I mean some of this thing give you a severe headache thinking about it. But, the analogy is with real numbers let us take the real numbers a real numbers basically consists of the rationales and the air rationales. The rationales are a countably infinite set. The real's are an unaccountably infinite sets their fore clearly the set of irrationals this is unaccountably infinite. And its exactly the same whatever, argument you might have applied to the real's to. E ssentially we are looking here essentially here looking at an extension of numbers in and cadnalities to infinite sets.

So, what we are saying is that the number of rationales is really the same as the number of the number of integers or number of naturals. But, the number of irrationals is really the same is the number of real's. And its and it is notch higher. In the case of your in countably infinite sets also you take any count ably infinite set it what we do. So one thing is clear no set no no set weather finite or countable or uncountable no set has the same number of elements as it is power set. Is a simple diagnolisation argument which will show that in case a set a can we place to in one to one

correspondence with its power set 2^a . And then it can actually create a diagonalisation argument which shows that any any kind of the that there is their exists are sub set. Which you are not accounted for. So, which destroys the notion of the 1 to 1 corresponding so this is this a very standard thing that we can show.

So, one thing we can show is that no set can be placed in 1 to 1 correspondence with its power sets. Which means no set the cardinality of no's of any set cannot be the same as the cardinality of its power set. But, then ones you got that the cardinality of a set is different from the cardinality of its power set. We can defiantly ask the questions, What is the cardinality of this set of finite sub sets of the set? And what is a cardinality of the set off infinite sub sets of this sets? If the set is the original set is infinite we can ask this questions. So, in the case of this and just like, you go through these proofs for real numbers and rationales and irrationals. You can go through similar proofs to show that the number of finite sub sets of a count ably infinite set is actually countable. And the number of infinite sub sets is actually uncountable.

And therefore the total number of sub sets of an infinite sets of a countable infinite set is actually uncountable infinite. So, I do not want to get into that but this is so that this. The compactness theorem says that i just required the all the finite sub sets to be satisfied. And I can guaranty that original infinite set will be satisfied.

(Refer Slide Time: 33:39)

Proof of the Compactness Theorem

Proof: Let Γ be a countably infinite set of propositions. Then clearly Γ may be enumerated in some order, say

$$\{\phi_0, \phi_1, \phi_2, \dots\} \quad (3)$$

where each ϕ_j has the unique index $j \geq 0$. For each $m \geq 0$, let $\Gamma_m = \{\phi_0, \phi_1, \phi_2, \dots, \phi_m\}$.

Claim. *Every nonempty finite subset of Γ is satisfiable iff for each $m \geq 0$, Γ_m is satisfiable.*

\vdash (\Rightarrow) clearly holds since each Γ_m is a finite subset. \Leftarrow

(\Leftarrow) Let $\emptyset \neq \Delta \subseteq_f \Gamma$. Let $k \geq 0$ be the index of the formula with the highest index in Δ . Clearly $\Delta \subseteq_f \Gamma_k$. Since the set Γ_k is satisfiable, by corollary 10.2, Δ is also satisfiable. \dashv

Hence it suffices to prove that if each of the $\Gamma_i, i \geq 0$ then Γ is satisfiable.

Consider a tableau \mathcal{T}_0 rooted at Γ_0 constructed using the **tableau rules**. Since Γ_0 is satisfiable, \mathcal{T}_0 has one or more open paths. Extend each of the open paths with the formula ϕ_1 and continue the tableau. The resulting tableau \mathcal{T}_1 is for the set Γ_1 and it does not close either. Hence tableaux \mathcal{T}_k for each Γ_k may be extended to yield open tableaux \mathcal{T}_{k+1} for Γ_{k+1} .

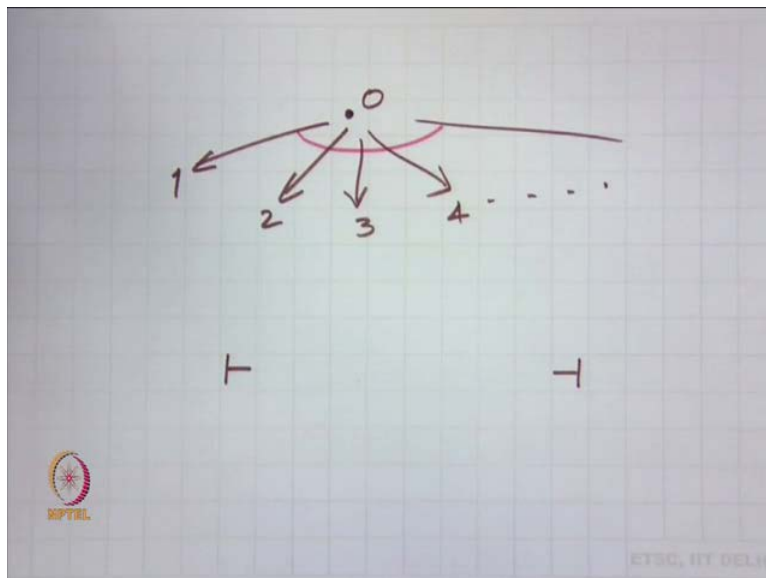

Navigation bar: Home Page, On Back, Full Screen, Close, 118 of 125, Quit

So, let us look at the proof of this theorem. So, let us, so if let me start with a set γ . Which is countably infinite and it has. If it is countably infinite then basically it can be placed in 1 to 1 correspondence with the naturals.

Which means I can essentially enumerate the set of formulae and γ and index them with naturals. So, I can talk about ϕ_0 , then ϕ_1 , ϕ_2 all the elements in γ can be enumerated corresponding to whatever 1 to 1 correspondence with the naturals you may choose to define. So, typical for any natural j ϕ_j is essentially is the j plus 1 the element in this enumeration like. And now what I can do is take this enumeration I can consider all this finite subsets γ_j for example. So, γ_j just consists of the first j sentences in the enumeration. So, where I have written γ_m should be this m minus 1 it this lets look at γ_m may be its may be its does not matter.

But, lets think of γ_m as consisting of ϕ_0 to ϕ_{m-1} the first m elements in the enumerations. So, one thing is every non empty finite I have a pequrearway of sometimes writing proofs. Which is that I state claims and a create approves. So, this that you see here there is a claim, which is under line and in italics.

(Refer Slide Time: 35:43)

And then there are these two symbols turn style and left turn style and turn style which actually bracket the proof of only this claim. So, that so it is this is like a lot like program structuring in

any kind of structure programming thing. You would like to divide up your program into various functions and then use those functions in some name way. So, this claims are like some functions in a program. And we will see the analogy with programming in the proof theory also that we do. But, essentially possible to have a nested structure of theorems and proofs especially of proofs. So, that you can have a individual claims sub claims and so on so forth and very much of like programmers. So, here is a claim which actually is not very important. It just says that every non empty finite sub set of γ by the way and it also follows the usual spoke rules of programming I mean. So, γ as already been declared in the outer spokes. So, it is available in the innerscopia unless it is renamed.

So, it follows all the structure programming a rules. So, every non empty finites are and basically so all the properties that you have defined before are available in here, follows exactly the program structure that we normally would like to employ. Every non empty finite sub sets of a γ is satisfiable if and only if for every $m \in \gamma$ m is also is satisfied. So, this is one thing of course is clear if every nonempty finite sub set of γ is satisfied will than clearly each $m \in \gamma$ being a finite sub set also a satisfiable. Other thing is given this particular order of $m \in \gamma$ given that there is a particular. So, take can you claim make the same claim that all all the finite sub set are also satisfied. So, will just go from finitery.

So, you take any finite sub set δ by the way this is my notation sub set with sub script f means it's a finite sub set. So, and of course this is non empty finite sub set we are only looking at non empty finite subsets. So, take let δ be any nonempty finite sub set then clearly there is an $m \in \gamma$ in which such that δ is also a subset of m . So, δ contains these various formulae from the enumeration $\phi_0, \phi_1, \phi_2, \phi_3$ etcetera and they all index by the naturals. So, there is a highest index in δ . So, now i just take γ_m or γ_{m+1} their. That will include every sentence chosen in δ . So, δ is a subset of some γ_m or some γ_k .

Satisfiability of Infinite Sets

From corollaries 9.4 and 9.5 we have

Corollary 10.1 A finite set Γ is unsatisfiable iff there is a closed tableau rooted at Γ .

Corollary 10.2 If a finite set Γ is satisfiable then every nonempty subset of Γ is satisfiable too.

Question 1. Suppose Γ were a denumerable (countably infinite) set. Under what conditions is Γ satisfiable?

Question 2. Suppose every subset of a denumerable set Γ is satisfiable. Then is Γ necessarily satisfiable?

Question 3. Suppose that only all finite subsets of a denumerable set Γ are satisfiable. Then is Γ satisfiable?

The slide also features a navigation bar at the bottom with icons for Home, Back, Forward, and other presentation controls.

So, then Γ_k is satisfiable we know that any finite subset of Γ is Γ_k is also is satisfied. Because the same truth assignment which was used to satisfied all the sentences and Γ_k can be used for all these sentences in Γ and will be true. So, now the our theorem proof of the compactness theorem reduces to essentially showing that if each of the Γ_k is satisfiable then Γ is also satisfiable. So, what do I do, I start I am going to use it tableau method. So, I start with Γ not so Γ_k just consists of that formulae ϕ_k create a tableau for it. The assumption is that Γ is a count ably infinite set of propositions in which each subset of Γ is satisfiable. So, a single Γ_k set is also a subset and so their fore what does is mean it means that this tableau rooted at Γ_k this tableau at Γ_k naught. The essentially a tableau rooted at this at the formulae ϕ_k naught does not close. Since that means ϕ_k naught is satisfiable.

(Refer Slide Time: 40:32)

So, I have this tableau which so I have this tableau which essentially starts with ϕ naught. And it might have some close branches but, the fact that ϕ naught is satisfiable means at there is at least one open branch. Now, what do I do in this open branch I also had ϕ_1 . So, I extend it to ϕ_1 so now what do I do I continue the tableau ϕ_1 is some complex formulae. And I continue this tableau this will again have some close branches. But, this is this whole thing is essentially a tableau for this set ϕ naught ϕ_1 . And that is a finite set and it is satisfiable and their fore there must be one open branch. I add ϕ_3 there and so on. I essentially and then basically then I get an extended tableau. Which is a tableau for a subset $\gamma_3 \phi$ naught ϕ_2 for γ_2 . And then γ_3 and so on and so far.

So, now so essentially i start with a tableau t not extended to tableau t_1 extended to tableau t_2 and so on so fore. And since each of these γ_m s is a finite set each of them is satisfiable. So, for each m tableau t_m has at least one open path. Then by quenisclamer I and this this tableau is a finitely branching tree. So, their exists an in an infinite tree such that all the formulae is ϕ_i in the set γ accruate some stage on open paths. So, basically all I am saying is.

(Refer Slide Time: 40:02)

So we take all the open paths and I should have mention that in every open path we put ϕ_1 here. And and when you put ϕ_2 you put it on every open path. Because you do not know which one might close and which one not close.

But, what the satisfiability of each finite assures you that there is always going to be at least one open paths. And that open paths will have an occurrence of each of the ϕ_i at some stage or the other. At and that will an infinite path by quenisclamer. And it will never close so every one of this formulae ϕ_1 to ϕ_n occur in at least one path. So, the fact that there an infinite set collection of formulae the entire γ occurs in this path. Which is not closed and therefore this γ must be satisfied. Why must γ must be satisfiable? Your tableau construction creates hintikka sets, so take (Refer Slide Time: 44:22)

So, supposing you take you take this open path starting from phi naught what we were shown last yesterday is that. If, you add if you look at all the formulae their this is actually a hentikka-set. H naught and the addition of phi1 and an open path here, is and an open path here. Essentially is a hintikka set for phi naught phi1 and for each gamma m therefore if i just collect all the formulas in the path I get hintikka set for gamma m. For every m for every gamma m there is a hintikka set if i just follow the path and what we know is that is hintikka sets or always satisfiable.

(Refer Slide Time: 45:14)

Tableaux Rules

	$\neg\neg . \frac{\neg\neg\phi}{\phi}$
$\wedge . \frac{\phi \wedge \psi}{\phi}$	$\neg\wedge . \frac{\neg(\phi \wedge \psi)}{\neg\phi \mid \neg\psi}$
$\wedge . \frac{\phi \wedge \psi}{\psi}$	
$\vee . \frac{\phi \vee \psi}{\phi \mid \psi}$	$\neg\vee . \frac{\neg(\phi \vee \psi)}{\neg\phi}$
$\rightarrow . \frac{\phi \rightarrow \psi}{\neg\phi \mid \psi}$	$\neg\rightarrow . \frac{\neg(\phi \rightarrow \psi)}{\phi}$
$\leftrightarrow . \frac{\phi \leftrightarrow \psi}{\phi \wedge \psi \mid \neg\phi \wedge \neg\psi}$	$\neg\leftrightarrow . \frac{\neg(\phi \leftrightarrow \psi)}{\phi \wedge \neg\psi \mid \neg\phi \wedge \psi}$

So, you this that application of the the first ser of the tableau rules and you think of it collecting all this formulas along the open path. And and what we showed last time was we showed that, every hintikka set is satisfiable here. A hintikka set every hentice set is satisfiable.

(Refer Slide Time: 45:28)

Tableaux Rules: Restructuring

In general the **elongation and branching rules** of the tableau look like this

Elongation. $\frac{\phi}{\psi \quad \chi}$	Branching. $\frac{\phi}{\psi \mid \chi}$
---	---

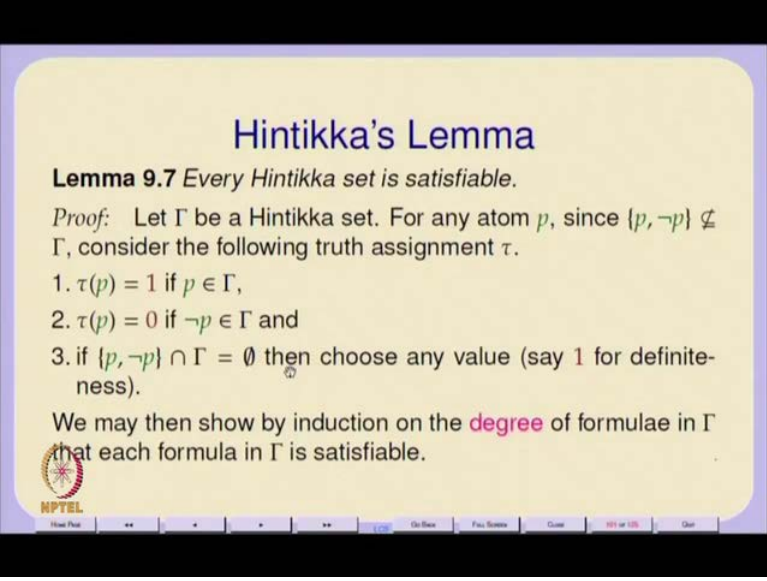

where ψ and χ are **subformulae** of ϕ .
 Let $\Gamma = \Delta \cup \{\phi\}$ where $\phi \notin \Delta$ be a set of formulae. It will be convenient to use sets of formulae in the tableau rules. The elongation and branching rules are rendered as follows respectively

Elongation. $\frac{\Delta \cup \{\phi\}}{\Delta \cup \{\psi, \chi\}}$	Branching. $\frac{\Delta \cup \{\phi\}}{\Delta \cup \{\psi\} \mid \Delta \cup \{\chi\}}$
--	---

So, we showed this last time and what we are and what this open path contains a only hintikka's sets the path is infinite because it does not close. And by quenisclamer and of course every element of gamma appears in it is an open path and it Is.

(Refer Slide Time: 45:29)

Hintikka's Lemma

Lemma 9.7 Every Hintikka set is satisfiable.

Proof: Let Γ be a Hintikka set. For any atom p , since $\{p, \neg p\} \not\subseteq \Gamma$, consider the following truth assignment τ .

1. $\tau(p) = 1$ if $p \in \Gamma$,
2. $\tau(p) = 0$ if $\neg p \in \Gamma$ and
3. if $\{p, \neg p\} \cap \Gamma = \emptyset$ then choose any value (say 1 for definiteness).

We may then show by induction on the **degree** of formulae in Γ that each formula in Γ is satisfiable.

NPTEL

A Hintikka's set remember that the fact at its still its an infinite path. So, I cannot conclude therefore that it is directly satisfiable. What allows me to conclude their it is satisfiable is the fact that what this path has is an hintikka set. And all hintikka sets are satisfiable by this lemma. So, say essentially the tableau for T_m has a hintikka se in it for each m . By queanisclama sense there is an infinite path. And it is not closed at but, that infinite path if I collect all the formulae in that infinite path. The set of all formulae that accrue in that hintikka path in that infinite path is a hintikka set. And all hintikka sets are satisfiable and their fore this entire path infinite path is satisfiable so the formulae in this path are satisfiablethe which means that gamma which is just a subset of this original hintikka of this hintikka set is also satisfiable.

(Refer Slide Time: 47:17)

Consider the final tableau \mathcal{T} obtained by this process of extension. \mathcal{T} is a *finitely branching infinite tree* with at least one path that does not close. By König's Lemma 10.12 there is an infinite path. Let Φ be the set of all formulae in this path. Since this path contains each of the formula $\phi_i \in \Gamma$, we have $\Gamma \subseteq \Phi$ and further Φ is a Hintikka set. By Hintikka's lemma 9.7 this set must be satisfiable. ■

So, I think we are formally started logic at a point where we probably do not think of this. And so, we have this compactness theorem and it has some fairly serious consequences one is the notion of inconsistency.

(Refer Slide Time: 47:37)

Inconsistency

We have earlier defined **consistency** of a set of formulae as being the same as satisfiability. In view of the compactness theorem 10.13 and its corollary 10.14

Definition 10.15 A set Γ is **inconsistent** if some nonempty finite subset of Γ is unsatisfiable.

Facts 10.16

1. Any superset of an inconsistent set is also inconsistent.
2. Any set containing a complementary pair is inconsistent.
3. (see table) If $\Delta \cup \{\psi, \chi\}$ is inconsistent then so is $\Delta \cup \{\phi\}$ where $\phi \equiv \psi \odot \chi$
4. (see table) If both $\Delta \cup \{\psi\}$ and $\Delta \cup \{\chi\}$ are inconsistent then so is $\Delta \cup \{\phi\}$ where $\phi \equiv \psi \oplus \chi$.

So, we defined Inconsistency as this being the same as satisfiability. So, inconsistency is just lack of consistency. But, the compactness theorem essentially says that if the set gamma is if you

have an infinite set Γ . Which is consistency if every set finite subset of it consistent then this infinite set Γ is also consistent.

(Refer Slide Time: 47:42)

Consistency

Definition 9.1 A set Γ of formulas is **consistent** if it is satisfiable i.e. there is a truth assignment under which every formula of Γ is true.

Lemma 9.2 Each tableau rule preserves satisfiability in the following sense.

Elongation Rules $\frac{\Gamma}{\Gamma'}$ If the numerator Γ is satisfiable then so is the denominator Γ' .

Branching Rules $\left(\frac{\Gamma}{\Gamma' \mid \Gamma''}\right)$ If the numerator Γ is satisfiable then at least one of the denominators Γ' or Γ'' is satisfiable.

NPTEL

So, now inconsistency reduces to essentially taking the converses of both sides. Firstly the it is abuse that you have this corollary.

(Refer Slide Time: 48:28)

The Compactness Theorem

Theorem 10.13 (The Compactness Theorem) A (countably) infinite set is satisfiable if all its nonempty finite subsets are satisfiable. □

Corollary 10.14 Any (finite or infinite) set of formulae is satisfiable iff all its non-empty finite subsets are satisfiable.

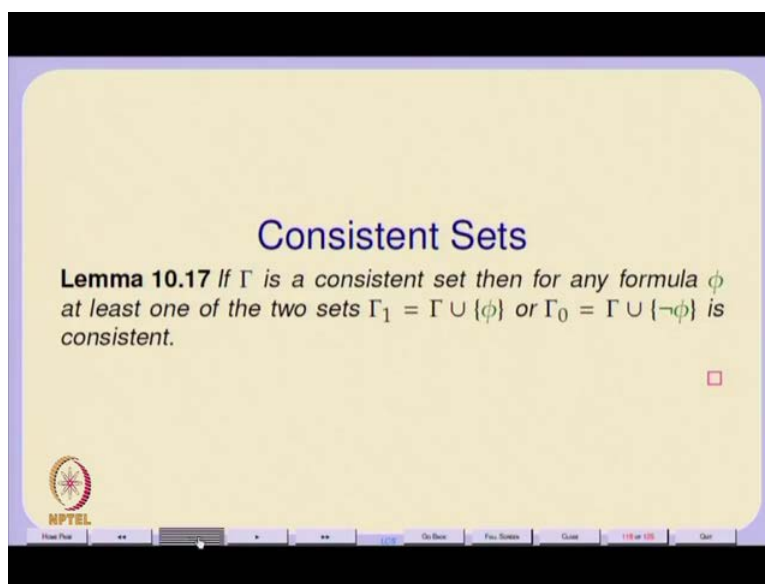

Note:

- If Γ is a countably infinite set then it can be placed in 1-1 correspondence with the set \mathbb{N} of naturals and hence there is some enumeration of its formulae and each formula carries an unique index from \mathbb{N} .

NPTEL

So, any finite or infinite set of formulae is satisfiable or consistent. If and only if, all its non-empty finite subsets are satisfied. This is a consequence of the compactness theorem. So, what this also means for inconsistency is that any finite or infinite set of formulae is inconsistent if and only if, there exists at least one non-empty finite subset which is inconsistent. So, inconsistency therefore reduces to this essentially why so we can think of this definition of inconsistency. Now, that we have the compactness theorem so we just say that a set Γ is consistent if there is no non-empty finite subset which is unsatisfied.

(Refer Slide Time: 49:40)

So, something is its clear satisfiability or consistency if Γ is consistent then any subset of it is also consistent. In the case of inconsistency it works out all together all you take inconsistency set Γ had a few more formulae into it it still remain inconsistent. So, any subset of an inconsistency set is going to be inconsistent. Because, the tableau which was used to prove let us say the inconsistency of the original set can be used without any change to show that this set is also the subset is also inconsistent. So, the other simple facts so that any set containing a complementary pair is obviously inconsistent it will never go to become a Hintikka set.

(Refer Slide Time: 50:44)

Hintikka Sets

Definition 9.6 A finite or infinite set Γ is a **Hintikka set** if

1. $\perp \notin \Gamma$ and for any $p \in A$, $\{p, \neg p\} \not\subseteq \Gamma$,
2. If $\phi \equiv \psi \odot \chi \in \Gamma$ for $\odot \in \{\wedge, \neg \vee, \neg \rightarrow\}$ then $\{\psi', \chi'\} \subseteq \Gamma$,
3. If $\phi \equiv \psi \oplus \chi \in \Gamma$ for $\oplus \in \{\vee, \neg \wedge, \rightarrow, \neg \leftrightarrow\}$ then $\{\psi', \chi'\} \cap \Gamma \neq \emptyset$

where ψ' and χ' are defined by the following table

$\phi \equiv \psi \odot \chi$	ψ'	χ'	$\phi \equiv \psi \oplus \chi$	ψ'	χ'
$\psi \wedge \chi$	ψ	χ	$\neg(\psi \wedge \chi)$	$\neg\psi$	$\neg\chi$
$\neg(\psi \vee \chi)$	$\neg\psi$	$\neg\chi$	$\psi \vee \chi$	ψ	χ
$\neg(\psi \rightarrow \chi)$	ψ	$\neg\chi$	$\psi \rightarrow \chi$	$\neg\psi$	χ
			$\psi \leftrightarrow \chi$	$\psi \wedge \chi$	$\neg\psi \wedge \neg\chi$
			$\neg(\psi \leftrightarrow \chi)$	$\neg\psi \wedge \chi$	$\psi \wedge \neg\chi$

And of course our notions of multiplicated and additive operators our give us this facts. So, we had these notions of multiplicative and additive operators. So, for each minary operator multiplicative additive operator of the form I mean. So, with component say and kay we had a corresponding say prime and kay prime. So, you take this if you so the notions of inconsistency essentially say that if I take say prime and kay prime and additive said delta and that that is set is inconsistency. Then just adding phi to delta also makes the set delta union phi inconsistency. In in the case of the multiplicative operators in the case of additive operators you had only say prime or you only phi prime. If both of them are inconsistency then, adding phi makes the certain consistence like an this is justan doing the converses with negations starting from the characterization of consistency as finite or infinite set gamma is consistant. If and only if all it is finite nonempty finite are consistence.
