Lecture - 16
The Hilbert System : Completeness

From yesterday's lecture there the hilbert system changing the terminology to soundness rather than consistency. So, that we reserve consistency for a set of segments and we think of system is being sound and which is a which is fairly well known which is a fairly failures word for prove system in general. So, might have just used that. So, we are talking and of course, the main reason for that is that you know it is a its possible to prove inconsistent things if you are set of assumptions inconsistence. So, the soundness of a theory does not does not necessary mean you cant prove any inconsistencies right if you make an inconsistencies set of assumptions you can actually prove inconsistencies things which is fine that is way its important to define the soundness.

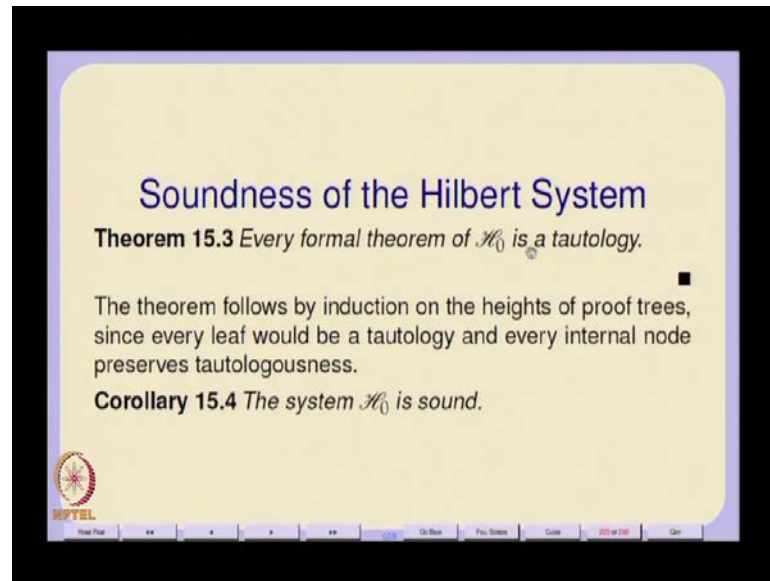

(Refer Slide Time: 01:21)

As being one in which you cannot prove all possible set things I mean or rather not all possible sentences are theorems formal theorems so; that means, given an empty set of assumptions whatever you can prove should not be the entire language that is. So, that is an notion of soundness of a formal theory and lets quickly go through it. So, basically we showed that every instance of every axiom schema's and the Hilbert system is a proctology and more rule actually preserves property of tautologousness right of right.

So, so which and since we know that not all formulae in the language I will not our tautologies says it may shows that the Hilbert system is sound right. So, so as I said the proof of soundness it just means that showing each of the axiom schema's the actually is a kind of a template for a class of tautologies following a certain pattern right and and proof that modest pronouns tautologousness is also something that is easily done.

(Refer Slide Time: 02:38)

Soundness of the Hilbert System

Theorem 15.3 Every formal theorem of \mathcal{H}_0 is a tautology. ■

The theorem follows by induction on the heights of proof trees, since every leaf would be a tautology and every internal node preserves tautologousness.

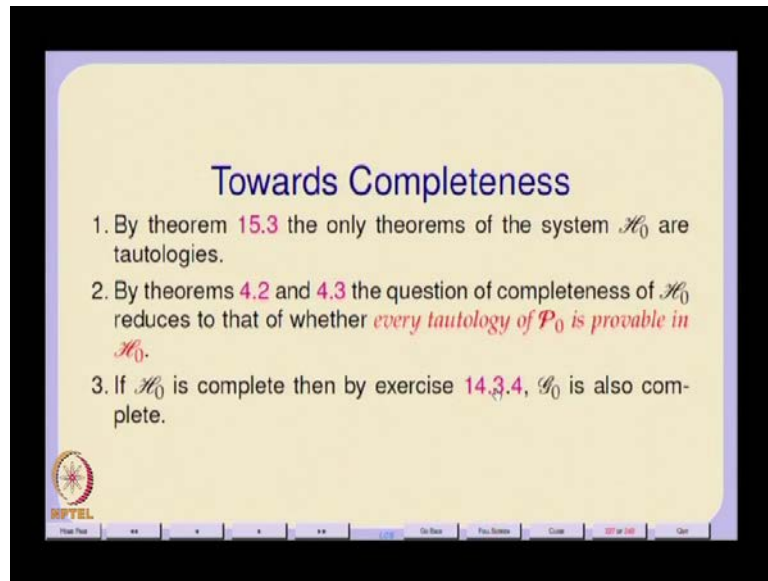

Corollary 15.4 The system \mathcal{H}_0 is sound.

NPTEL

Home Page ** * ** Go Back Previous Next Quit 22 of 28

So, and from the soundness of the Hilbert system we also get that every formal theorem; that means, every statement that you can prove without any assumptions is a tautology and therefore, the system is sound and now lets actually look at the completeness.

(Refer Slide Time: 03:04)

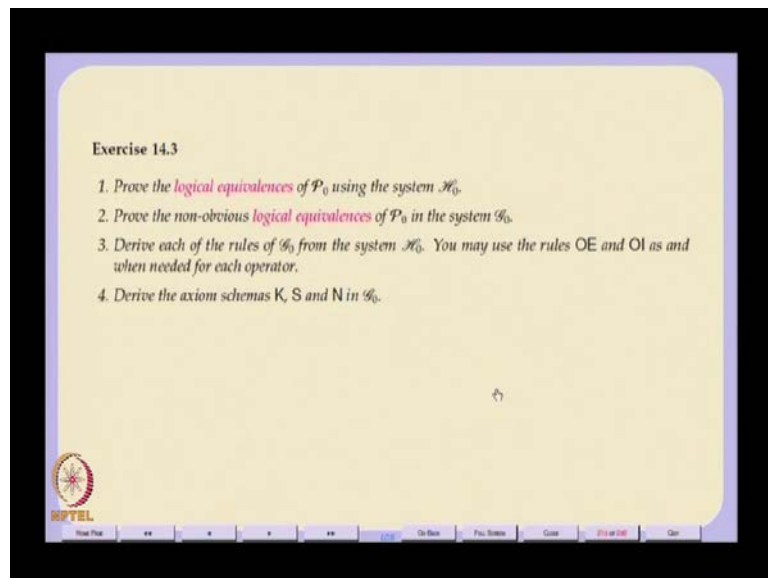

Towards Completeness

1. By theorem 15.3 the only theorems of the system \mathcal{H}_0 are tautologies.
2. By theorems 4.2 and 4.3 the question of completeness of \mathcal{H}_0 reduces to that of whether *every tautology of \mathcal{P}_0 is provable in \mathcal{H}_0 .*
3. If \mathcal{H}_0 is complete then by exercise 14.3.4, \mathcal{G}_0 is also complete.

MPTEL

So, what I said was. So, one thing is that the only formal theorems are the system are tautologies and, but we need for for completeness we need to show that every tautology is. In fact, provable in the system right.

(Refer Slide Time: 03:28)

Exercise 14.3

1. Prove the *logical equivalences* of \mathcal{P}_0 using the system \mathcal{H}_0 .
2. Prove the *non-obvious logical equivalences* of \mathcal{P}_0 in the system \mathcal{G}_0 .
3. Derive each of the rules of \mathcal{G}_0 from the system \mathcal{H}_0 . You may use the rules OE and OI as and when needed for each operator.
4. Derive the axiom schemas K, S and N in \mathcal{G}_0 .

MPTEL

So, and then a consequence of that is that is the hilbert system is complete then by this exercise in which you derive the axiom schemas k s and n in the gensis system if you flow the gensisi system is also complete right.

(Refer Slide Time: 03:41)

Towards Truth-tables

1. Restricting ourselves to showing that every tautology is provable in \mathcal{H}_0 is sufficient.
2. But we proceed to show that every truth table can be *simulated* as a proof in \mathcal{H}_0 , thereby capturing all of the semantic features of the language \mathcal{P}_0 in its proof theory.

NPTEL

And what I said was we will we were yesterday we were actually looking at simulating the truth table and in that proof of the simulation of the truth table they were quite a few errors. So, first thing I thought I would do is correct this those errors and the next thing I thought was I will actually go through the proof of completeness because its non trivial.

(Refer Slide Time: 04:07)

The Truth-table Lemma

Lemma 16.1 Let ϕ be a formula with $\text{atoms}(\phi) \subseteq \{p_1, \dots, p_k\}$. For each truth assignment τ ,

$$p_1^*, \dots, p_k^* \vdash \phi^*$$

where for each $i, 1 \leq i \leq k$,

$$p_i^* \equiv \begin{cases} p_i & \text{if } \tau(p_i) = 1 \\ \neg p_i & \text{otherwise} \end{cases}$$

and

$$\phi^* \equiv \begin{cases} \phi & \text{if } \mathcal{T}[\phi]_{\tau} = 1 \\ \neg \phi & \text{otherwise} \end{cases}$$

NPTEL

So, So, will stimulate a truth table. So, the simula. So, the truth table lemma as I call it essentially says that you take for any formula with whose atoms are contained in this set and some finite set p_1 to p_k for every truth assignment τ there is formal deduction

from the assumptions Γ the formula ϕ^* where Γ and ϕ^* are defined as being Γ and ϕ if the truth assignment τ gives truth value one otherwise the negation of Γ and ϕ here ok.

(Refer Slide Time: 04:48)

Proof of lemma 16.1

Proof: By induction on the number n of operators in ϕ . Let $\Gamma = \{p_1^*, \dots, p_k^*\}$.

Basis $n = 0$. Then ϕ is an atom say, $\phi \equiv p_1$. The claim then trivially follows since $p_1^* \equiv \phi^*$.

Induction Hypothesis (IH). The claim holds for all wffs with less than $n \geq 0$ occurrence of the operators.

Induction Step. Suppose ϕ is a wff with n operators. Then there are two cases to consider.

Case $\phi \equiv \neg\psi$, where ψ has less than n operators. Then by the induction hypothesis we have have a proof tree

$\begin{array}{c} \swarrow \mathcal{P}_1 \searrow \\ \Gamma \vdash \psi^* \end{array} \cdot \tau$

The slide also features the NPTEL logo and a navigation bar at the bottom.

So, this. So, as I said. So, we are going to this proof is by induction on the number n of operators in the formula ϕ . So, and the set of assumptions the set Γ which is. So, essentially we are taking some particular row of the truth table and Γ to Γ^* of the set of assumptions if that number of operators and ϕ is the zero then ϕ must be an atom and therefore, it trivially follows that Γ^* is syntactically the same as ϕ^* and therefore, and that is provable right.

Part of the monotonic considerations and that is provable and any anywhere you can prove $\Gamma \vdash \phi$ without any assumption and then by the deduction theorem you can move the left Γ to the assumption and therefore, you are proved proved this. So, assume this induction hypothesis that for all the claim holds for all well found formulas of which have less than n operators and we take this inductions step. So, the induction step of course, is by case analysis on this structure of the formula. So, let us assume that ϕ is a formula with n operators and then we have two cases to consider essentially one is where ϕ is of the form $\neg\psi$ where ψ has less than n operators.

(Refer Slide Time: 06:19)

Subcase $\mathcal{T}[\psi]_{\tau} = 1$. Then $\mathcal{T}[\phi]_{\tau} = 0$ and $\psi^* \equiv \psi$ and $\phi^* \equiv \neg\psi$. Then we have the following deduction.

$$\frac{\text{DNI} \rightarrow \frac{\Gamma \vdash \psi \rightarrow \neg\neg\psi \quad \begin{array}{c} \swarrow \mathcal{T}_1 \nearrow \\ \Gamma \vdash \psi \end{array}}{\Gamma \vdash \neg\neg\psi \equiv \phi^*}}{\text{MP} \quad \Gamma \vdash \neg\neg\psi \equiv \phi^*}$$

Subcase $\mathcal{T}[\psi]_{\tau} = 0$. Then $\mathcal{T}[\phi]_{\tau} = 1$ and $\psi^* \equiv \neg\psi$ and $\phi^* \equiv \psi$. By the induction hypothesis we have $\Gamma \vdash \neg\psi \equiv \phi^*$.

Case $\phi \equiv \psi \rightarrow \chi$, where each of ψ and χ has less than n operators. By the induction hypothesis there exist proof trees $\begin{array}{c} \swarrow \mathcal{T}_1 \nearrow \\ \Gamma \vdash \psi^* \end{array}$ and $\begin{array}{c} \swarrow \mathcal{T}_2 \nearrow \\ \Gamma \vdash \chi^* \end{array}$. Here again we have three subcases.

And the other case is when phi is of the form some sie arrow kie where each of sie and kie has less than n operators right. So, the case when phi is not sie then we by the induction hypothesis we actually have a proof tree t one where from assumption gamma you can actually prove sie star whatever that is yeah. So, then of course, when you have two sub cases one is with the truth assignment sie is one or zero. So, in each case what happens is if. So, if the truth assignment to sie is one then phi must be zero because phi is not sie and therefore, sei star is the same as sie and phi star is naught phi which is the same as naught of naught of sie and then this this deduction essentially shows that from gamma you can prove phi phi star yeah this prove tree essentially shows this given that so.

Actually. So, so we actually had gamma proves sie star, but I have written gamma proves sie here because we know sie star is the same as sie right in the case when sie is been assigned zero by the is assigned false by the truth assignment then t of phi must be true I mean phi must be true therefore, sie star is not sie and sie star is tee same as phi. So, it is also naught not sie by the induction hypothesis we have this and and the proof is clear in the case when phi is of the form sie arrow phi we have essentially three sub cases when sie is assigned false clearly it does not matter what kie is when kie is assigned true clearly it does not matter what sie is the only other case third case is when sie is assigned false.

(Refer Slide Time: 08:29)

Subcase $\mathcal{T}[\psi]_{\tau} = 0$. We have $\psi^* \equiv \neg\psi$ so tree \mathcal{T}_1 is $\begin{array}{c} \swarrow \mathcal{T}_1 \searrow \\ \Gamma \vdash \neg\psi \end{array}$, $\mathcal{T}[\phi]_{\tau} = 1$ and $\phi^* \equiv \phi \equiv \psi \rightarrow \chi$. We then have the proof tree

$$\text{MP} \frac{\perp \overline{\Gamma \vdash \neg\psi \rightarrow (\psi \rightarrow \chi)} \quad \begin{array}{c} \swarrow \mathcal{T}_1 \searrow \\ \Gamma \vdash \neg\psi \end{array}}{\Gamma \vdash \psi \rightarrow \chi \equiv \phi^*}$$

which proves the claim.

Subcase $\mathcal{T}[\chi]_{\tau} = 1$. Then $\chi^* \equiv \chi$ and $\mathcal{T}[\phi]_{\tau} = 1$ and $\phi^* \equiv \phi \equiv \psi \rightarrow \chi$. Hence tree \mathcal{T}_2 is $\begin{array}{c} \swarrow \mathcal{T}_2 \searrow \\ \Gamma \vdash \chi \end{array}$. We may then construct the following proof tree to prove the claim.

And kei is assigned true the I am sorry when sie is assigned true and kei is assigned false and that is the important case.

So, in each of these cases. So, in the case when sie is assigned false and it does not matter what kei is we have sie star as naught sie so; that means, our induction hypothesis says there is a proof tree t one of this form and phi must be therefore, b true which means phi star is the same as phi which is which must be syntactically sie arrow kei. So, now, we can we do not have this proof tree this is one of the exercises.

(Refer Slide Time: 09:15)

Exercise 14.2

1. Prove the axiom schema

$$\text{N'. } \frac{}{(\neg Y \rightarrow \neg X) \rightarrow (X \rightarrow Y)}$$

A deduction theorem variant of this schema is also called the modus tollens rule or the contrapositive rule.

2. A variant of the system \mathcal{H}_0 is the system \mathcal{H}_0' obtained by replacing the schema N by N'.

(a) Prove the axiom schema N in the system \mathcal{H}_0' .

(b) Prove the double negation rules DNE and DNI in \mathcal{H}_0' .

3. Prove the following axiom schemas in \mathcal{H}_0 . In each case you are allowed to use any version of the theorems previously proven.

(a) \perp . $\frac{}{\neg \mathcal{R} \rightarrow (X \rightarrow Y)}$ What can you conclude about the system \mathcal{H}_0 from your proof?

(b) $\text{N''}.$ $\frac{}{(X \rightarrow Y) \rightarrow (\neg Y \rightarrow \neg X)}$

You can see as you can prove $\neg \chi \rightarrow (\psi \rightarrow \chi)$ right. So, that and you can actually apply this \rightarrow inference rule and you can claim that from Γ you have proved $\neg \chi \rightarrow \psi \rightarrow \chi$ and you already have $\neg \chi$ here by modest pronence therefore, you have $\psi \rightarrow \chi$ which is the same as ϕ^* in the case when χ has been assigned one then χ^* is the same as $\neg \chi$ ϕ^* is been assigned one and therefore, ϕ^* is the same as $\psi \rightarrow \chi$. So, ϕ^* is the same as $\psi \rightarrow \chi$.

(Refer Slide Time: 10:09)

$$\frac{K \frac{}{\Gamma \vdash \chi \rightarrow (\psi \rightarrow \chi)} \quad \swarrow \mathcal{T}_2 \nearrow \Gamma \vdash \chi}{MP \frac{}{\Gamma \vdash \psi \rightarrow \chi \equiv \phi^*}}$$

Subcase $\mathcal{T}[\psi]_{\tau} = 1$ and $\mathcal{T}[\chi]_{\tau} = 0$. Then $\psi^* \equiv \psi$ and $\chi^* \equiv \neg \chi$ and $\mathcal{T}[\phi]_{\tau} = 0$ from which we get $\phi^* \equiv \neg(\psi \rightarrow \chi)$. By induction hypotheses we therefore have the trees $\swarrow \mathcal{T}_1 \nearrow \Gamma \vdash \psi$ and $\swarrow \mathcal{T}_2 \nearrow \Gamma \vdash \neg \chi$ using which we construct the following proof tree to prove our claim.

So, we have this proof tree proving $\psi \rightarrow \chi$ by the induction hypothesis and then we can use that proof of tree starting with the axiom K where you have $\neg \chi \rightarrow \psi \rightarrow \chi$ and you have proved $\neg \chi$ in this proof tree and therefore, you have $\psi \rightarrow \chi$ which is the same as ϕ^* yeah the last sub case ϵ ψ has been assigned one and χ has been assigned zero clearly ψ is not true since ψ is of the form $\psi \rightarrow \chi$ right.

So, which means that. Firstly, ψ^* is the same as ψ and χ^* is not χ and ϕ^* is $\neg(\psi \rightarrow \chi)$. So, we have these proof trees T_1 and T_2 by the induction hypothesis which from the same assumptions Γ prove respectively ψ and $\neg \chi$ which is ψ and χ^* which is $\neg \chi$.

(Refer Slide Time: 11:10)

(c) N2. $\frac{}{X \rightarrow (\neg Y \rightarrow \neg(X \rightarrow Y))}$

(d) C. $\frac{}{(X \rightarrow Y) \rightarrow ((\neg X \rightarrow Y) \rightarrow Y)}$ Derive the proof by cases rule Cases. $\frac{\Gamma, X \vdash Y \quad \Gamma, \neg X \vdash Y}{\Gamma \vdash Y}$

(e) Derive the proof by contradiction also called the indirect proof method rule I in the system \mathcal{M}_6 .

I. $\frac{\Gamma, X \vdash \neg Y \quad \Gamma, X \vdash Y}{\Gamma \vdash \neg X}$

And now what we do is we have this derived rule here which says x arrow \neg y arrow \neg x arrow y right if you proved ψ you can use this derived rule along with t one.

(Refer Slide Time: 11:23)

N2 $\frac{}{\Gamma \vdash \psi \rightarrow (\neg \chi \rightarrow \neg(\psi \rightarrow \chi))}$ $\swarrow \mathcal{F}_1 \nearrow$

MP $\frac{\Gamma \vdash \psi \rightarrow (\neg \chi \rightarrow \neg(\psi \rightarrow \chi)) \quad \Gamma \vdash \psi}{\Gamma \vdash \neg \chi \rightarrow \neg(\psi \rightarrow \chi)}$ $\swarrow \mathcal{F}_2 \nearrow$

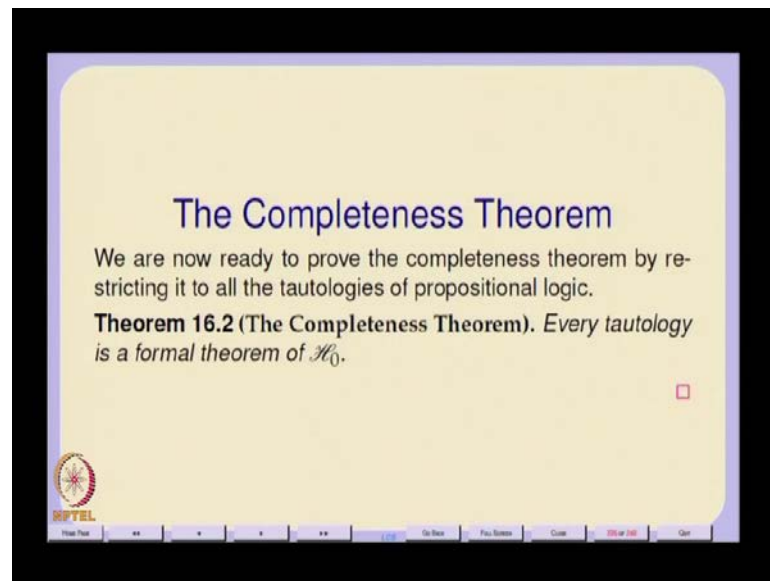

$\frac{\Gamma \vdash \neg \chi \rightarrow \neg(\psi \rightarrow \chi) \quad \Gamma \vdash \neg \chi}{\Gamma \vdash \neg(\psi \rightarrow \chi) \equiv \phi^*}$

Which proves ψ apply modest ψ to get $\neg \chi$ arrow $\neg(\psi \rightarrow \chi)$ and of course, you have by the induction hypothesis this proves ψ with the conclusion $\neg \chi$. So, you can again apply the modest ψ rule to get $\neg(\psi \rightarrow \chi)$ which is the same as ϕ^* . So, those those exercises

called were actually important in order to show that you you can simulate every row of a truth table by by a proof by a deduction from assumptions.

Ah from the assumptions which are the truth values essentially of the atoms of the truth table right.

(Refer Slide Time: 12:18)

So, now. So, the actual completeness theorem has to show that every tautology in \mathcal{L} is a formal theorem of the system \mathcal{H} and though I thought it was though I initially felt it was sort of like obvious if you simulated the entire truth table and you have intuitively clearly captured all the schematics. So, that intuition is fine, but the formal proof of this theorem still requires the fact that you are not allowed to have any assumptions right you are talking about every assumption every the truth table has assumptions right the atoms the truth assignments to the atoms are still assumptions in every proof. So, is it clear from there you can actually get down to proving every tautology and that step is not as I originally thought it was and this is a and it is also very beautiful proof as you can see. So, will go through this proof right.

(Refer Slide Time: 13:15)

Proof of the Hilbert Completeness Theorem 16.2

Proof: Let ϕ be a tautology expressed in the language \mathcal{L}_0 and let $atoms(\phi) = \{p_1, \dots, p_k\}$. Since every row of the truth-table for ϕ assigns it a truth value 1 we have $\phi^* \equiv \phi$. Each bit-string $s_k \in \{0, 1\}^k$ indexes a row of the truth table containing 2^k distinct rows. Let $\Gamma_{s_k} = \{p_i^* \mid 1 \leq i \leq k\}$ denote the set of assumptions for the s_k -th row of the truth table. Corresponding to each such s_k there exists a proof tree, $\Gamma_{s_k} \vdash \phi$. For each bit-string s_j , $0 \leq j \leq k$, we construct the proof tree $\Gamma_{s_j} \vdash \phi$.

Now consider any two proof trees whose indexes differ only

So, what we do have is that every row of the truth table cannot be simulated by a proof where the truth values of the atoms from the assumptions of that proof are right. So, what is. So, what I will do is. So, we will encode each row of the truth table with a standard by a bit string of if we are talking about atoms then each row of the truth table has essentially k columns one corresponding to each atom take the k atoms in the order p one to p k and take the truth assignment in that row as essentially a k length bit string right. So, now, what we are saying is. So, the back. So, the truth table lemma essentially says that for every such k length bit string s k I have a proof tree and we have to prove that every tautology is a formal theorem. So, assume phi is a tautology which means the truth table assigns the truth value true to in all rows of truth table to phi. So, phi star in this case by the truth table lemma is just phi itself.

So, now what this means is that corresponding to each row of the truth table I have proof tree $\Gamma_{s_k} \vdash \phi$ where the assumptions are Γ_{s_k} . So, I am using the same encoding to specify what is the truth assignment to each of the atoms with those atoms I can prove phi and that is this is this is given from the truth table lemma. So, for each now what we are going to prove is that you take any bit string s_j where j is the length less than or equal to k we are going to construct the proof tree $\Gamma_{s_j} \vdash \phi$ such that Γ_{s_j} proves phi. So, in the case when j is equal to k of course, we have already have these proof trees, but what we are going to do is we are going to systematically contract the assumptions till j becomes zero when j becomes zero essentially you got a $\Gamma_{s_0} \vdash \phi$ where s_0 is just a

empty string that is gamma epsilon and essentially that that is empty set of assumptions otherwise s_j for j less than or equal to k essentially gives you the truth assignment for each of the atoms p_1 to p_j and if and assuming that you have already removed the atoms p_{j+1} to p_k right. So, so. So, so. So, there are two raised to k rows on the truth table and we have two raised to k different proof trees one for each string s_k there are two raised to k strings bits strings of length k right. So, what we are going to do is we are going to contract this bit strings still you come to the empty bit string right. So, this is what. So, in order to do that consider two bit strings which differ only in the last bit in the right most bit. So, we. So, assume that you you. So, we have already got $t s_k$ right for all for all the case.

(Refer Slide Time: 17:15)

in the rightmost bit. That is, for any $s_{j-1} \in \{0,1\}^{j-1}$, we have the proof trees $\Gamma_{s_{j-1}1} \vdash \phi$ and $\Gamma_{s_{j-1}0} \vdash \phi$. We construct the proof tree $\Gamma_{s_{j-1}} \vdash \phi$ as follows.

$$\begin{array}{c}
 \begin{array}{c} \swarrow \mathcal{T}_{s_{j-1}1} \searrow \\ \Gamma_{s_{j-1}1} \vdash \phi \end{array} \quad \text{and} \quad \begin{array}{c} \swarrow \mathcal{T}_{s_{j-1}0} \searrow \\ \Gamma_{s_{j-1}0} \vdash \phi \end{array} \\
 \begin{array}{c} \swarrow \mathcal{T}_{s_{j-1}} \searrow \\ \Gamma_{s_{j-1}} \vdash \phi \end{array} \text{ as follows.} \\
 \\
 \begin{array}{c}
 \begin{array}{c} \swarrow \mathcal{T}_{s_{j-1}0} \searrow \\ \Gamma_{s_{j-1}0} \vdash \phi \end{array} \quad \text{DT} \Rightarrow \quad \begin{array}{c} \swarrow \mathcal{T}_{s_{j-1}} \searrow \\ \Gamma_{s_{j-1}} \vdash \phi \end{array} \\
 \text{MP} \frac{\Gamma_{s_{j-1}} \vdash \neg p_j \rightarrow \phi}{\Gamma_{s_{j-1}} \vdash \phi} \quad \frac{\Gamma_{s_{j-1}} \vdash p_j \rightarrow \phi \quad \text{C} \frac{\Gamma_{s_{j-1}} \vdash (p_j \rightarrow \phi) \rightarrow ((\neg p_j \rightarrow \phi) \rightarrow \phi)}}{\Gamma_{s_{j-1}} \vdash (\neg p_j \rightarrow \phi) \rightarrow \phi}}{\Gamma_{s_{j-1}} \vdash \phi}
 \end{array}
 \end{array}$$

We can thus eliminate the atom p_j from the assumptions by applying the above proof procedure to all pairs of proof trees

So, you take essentially. So, starting from any proof tree $t s_j$ you take s_j minus one zero and s_j minus one one. So, you got proof trees $t s_j$ minus one zero and $t s_j$ minus one one which proves from the assumptions Γ_{s_j} minus Γ_{s_j} minus one one it proves phi and from Γ_{s_j} minus one zero it proves phi right. So, this is a this is a this is a j length bit string this is also a j length bit string where s_j minus one is j minus one length bit string and then you have had have a one all zero. So, essentially we pair wise we choose the two bit strings which which are identical who have identical j minus one prefixes, but differ only in the j 'th bit right. So, what we. So, then what we are going to construct is a proof tree $t s_j$ minus one from these proof trees. So, this is very simple. So, this is how we are going to go about it. So, you take $t s_j$ minus one one which proves

from $\Gamma, s, j-1$ it proves ϕ and you apply essentially the deduction theorem. So, that you move the j 'th assumption to the right.

So, when you move the j 'th assumption to the right you get $\Gamma, j \rightarrow \phi$ right in the case of one you get $\Gamma, j \rightarrow \phi$ in the case of zero you get $\neg \Gamma, j \rightarrow \phi$ right and then we have this exercise of proof by cases right which shows that $x \rightarrow y$ and $\neg x \rightarrow y$ implies y essentially that is what it says. So, this is a proof by cases and. So, we essentially apply this proof by cases right. So, when you apply this proof cases and for these two conclusions $\Gamma, j \rightarrow \phi$ and $\neg \Gamma, j \rightarrow \phi$ you get that $\Gamma, s, j-1$ proves ϕ right. So, what we have done is we started with two raised to k different proof trees and we halve it by taking proof trees pair wise and creating proof trees two raised to $k-1$ proof trees with assumptions only from p_1 to p_{k-1} and this procedure of removing the right most assumption is very general is absolutely general. So, you can do this systematically one by one. So, we start with two raised to k proof trees halve it down to two raised to $k-1$ by removing the assumption p_k and $\neg p_k$ then you remove the assumption p_{k-1} and $\neg p_{k-1}$ and till you will actually obtain this a single monolithic proof tree right and this procedure is absolutely this procedure is absolutely general and this proof by cases works as generally right.

(Refer Slide Time: 20:50)

whose assumptions differ only in the value of p_j^* .

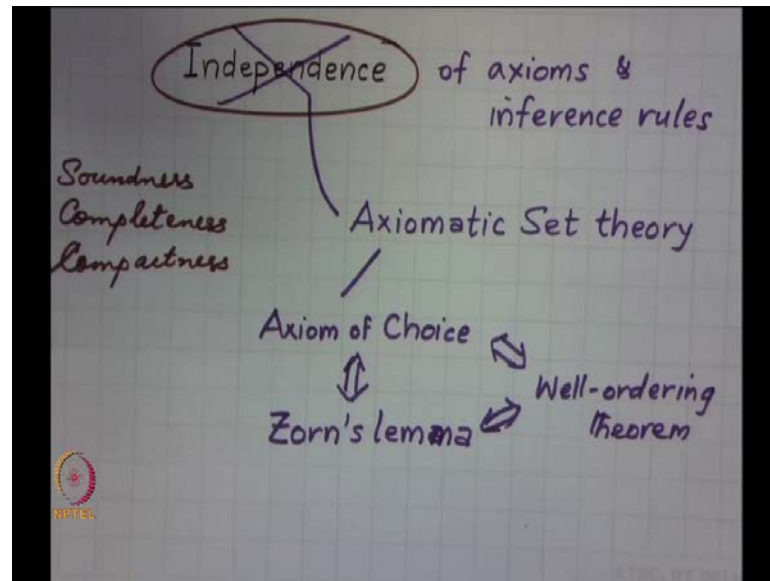

Thus the 2^k proof trees are combined pairwise to produce 2^{k-1} proof trees that are independent of the atom p_k . Proceeding in a like manner we may eliminate all the atoms one by one by using similar proof constructions so that finally we obtain a single monolithic proof tree $\Gamma_\epsilon \vdash \phi$ where $\Gamma_\epsilon = \emptyset$, thus concluding the proof that the tautology ϕ is a formal theorem of \mathcal{H}_0 . ■

MPTEL

So, this one monolithic proof tree essentially gamma epsilon is empty and therefore, you have proved that starting with the assumption phi is a tautology can actually be the proven right. So, so this is how this proof goes and this proof cannot be replicated the moment you have you have a system where the schematics is infinite tree right and that is precisely what is going to happen when we do first order logic right. So, this. So, which means we when we when we come to first order logic there are certain things that we will not have any access too one is the notion of the truth table or at least a finite truth table any logical notion of a truth table there with probably be infinite tree depending on the model that you are looking at depending on what you are trying to axiomatize. Secondly, there is. So, which means that this this proof is actually you need to this this construction and therefore, this proof will not such a proof cannot be extended easily to first order logic or anything which is which has an infinite tree schematically nature which might generate infinite infinite trees. So, on. So, right and you can see that this proof is also very different from the proof of completeness that we use to the tabular system right was there is question was not really of validity, but of set un satisfiability or satisfiability right and. So, you have different kinds of proofs and it is a good idea to actually look at. So, it is a it is a good idea to look at various different kinds of proofs where as the tabular method of completeness proof might actually be applicable even to other other systems which are infinite tree in nature, but this kind of proof will not be applicable then right.

So,. So, there is there is actually one more concept which I have not done, but which should which I will mention, but I will not proceed further with it and that is a very important concept, but I do not think we have the either the time or the where without to actually deal with it.

(Refer Slide Time: 23:32)

And that is the independence of axioms. So, there. So, we we had we had several important concepts in in a logic. So, we of course, we have already dealt with three important concepts one is of course, I mean besides soundness completeness compactness. So, these are the this are the three important these are the three important concepts there is fourth important concept called independence and that independence has to do with the question of. So, we have this notion of derived rules and derived operators h we also had this notion of adequacy and function completeness right. So, our functional completeness essentially said that every any operator that you might define in propositional logic can be expressed in terms of whatever the operators are well not actually it is a its enough to just have is adequate to just have the operators arrow and not right.

So, in that sense the operators any operator that you might define for propositional logic is not functionally independent of the operators arrow and naught this a similar and analogous notion is that of independence of axioms and inference rules right. So, one important thing that therefore, at which needs to be shown especially in a minimal system the hilbert system was suppose to be a minimal system is that the the two concepts I mean the the the axiom schemas of the hilbert system are mutually independent it it is not possible to take any sub set of those axiom schemas and inference rules and prove the rest as in a derived fashion this this independence is actually fairly a hard concept to prove, but its an important concept for example, its not a concept that is

easily applicable to something like natural deduction which is not meant to be a minimal system, but if you take a minimal system then you actually have to prove the independence of the axioms and the proofs of independence are general not not are not very easy. So, I will not actually go into them, but independence is as an impart is an important concept from the point of view of logical theory for other reasons.

So, yesterday I took the example of the parallel postulate right. So, what we what are what are we saying now I can remove uclid's parallel postulates and put another parallel postulate which says that there are no parallel lines basically and still get a consistent geometrical theory I can still have a sound geometrical theory. So, in that sense the parallel postulate is sort of independent of other axioms of uclid right and this independent notion also have comes up when you when you do something like axiomatic set theory right. So, one of the one of the most boolean proofs of independence was this. So, I do not know how much of axiomatic set theory you know. So, its possible to take tree set theory as an axiomatic theory very much like the wave you have defined within the domain of a stardology. So, which we have in the end yet done and one of the important things about axiomatic set theory is this notion of the axioms of choice which actually you have you have probably seen a different fashion because the axiom of choice is actually equivalent to other thing one is on's lemma and and the other is the well ordering theorem right yeah. So, so. So, and actually in any kind of in any kind of in in a large number of proofs we use a notion of a well ordering the fact that there are no infinite descending chains right and this. So, what for a long time it was assume that the axiom of choice which which essentially is required for which is required for any kind of proof that you have only a finite sequence or it is always possible to construct from an infinite set some finite from total ordering and. So, on and. So, forth all those things required this notion of either the axiom of choice or they require a form of well ordering or they require ones lemma, but what Pual in the sixtees well after axiomatic set theory was well established was that this axiom of choice is actually a independent of the other axioms of set theory. So, which means its possible to remove the axiom of choice and have a completely separate set of set theory separate axiom system for set theory or non standard set theory in which the axiom of choice may not be applicable the moment axiom of choice may not be applicable it also means you may not you may not use any kinds of well ordering you van not use ones lemma and. So, on. So, forth right and in that sense you still have a you can this the axioms of set theory still allow enough leaving

to adsorbed some of their axiom instead of the axiom of choice because axiom of choice itself is independent of time right, but this concept of independence otherwise in a first of logic is actually quite hard to understand where it ahs come up with some phenomenally interesting results on formal theories. So, I will not. So, this is a the concept that I will not touch on we will proceed straight to first order logic yeah and. So, today I will not late to start that right will I think will stop here today
