Generating Functions

In this lecture, we will learn about generating functions. Generating functions is a tool used to solve recurrence relation.

(Refer Slide Time: 00:36)

Let us first see some examples of recurrence relations. The first recurrence relation that we will see is a very simple recurrence relation. So, the first term a_0 is denoted as equal to 1 and a_n is defined in terms of the previous value and it is 3 times a_{n-1} . This is the familiar geometric series where the ratio of successive terms happens to be 3.

So, this recurrence relation basically gives a sequence of numbers. So, if you write down the sequence, the first number is 1, the next number is 3 times 1 that is going to be 3, 9 and so on. So, in this recurrence relation, it is very easy to give what is the n th term, the n th term by means of definition is going to be 3 times the previous term or the n minus first term, then we can therefore write a_n in a closed form as equal to 3 raised to n , okay, so this can be viewed as a solution for this recurrence relation.

We could take another recurrence relation where say we take a_0 is equal to 1 and a_n is equal to let us say $a_{n-1} + 5$. So, now what is the n th term, this is the arithmetic

progression, this is also easy to determine then the nth term, if you write down the sequence you get the sequence 1, 6, 11, 16 and so on. Therefore, a n is just going to be 5 into n plus 1, okay. So, you can think of this is a closed form solution to the recurrence relation that we are given.

We will look at a slightly more complicated recurrence relation. Let us say a0 is equal to 100 and a n is defined in terms of a n minus 1 as let us say 4 into a n minus 1 minus let us say 100. Now it is not so straightforward to determine just by mere inspection it is difficult to say what is the close form solution. We could say that a0 is 100, the next term is going to be 400 minus 100 that is 300 and the next term is going to be 1100, next term is going to be 4400 minus 100 that is 4300 and so on.

So, the general term is going to be slightly difficult to write down by mere inspection, okay. So, how do we find the solution to the nth term? For this we will use a very powerful method known as generating function that can be used to solve these kind of recurrence as well as much more complicated recurrence.

(Refer Slide Time: 04:04)

Clash of sine

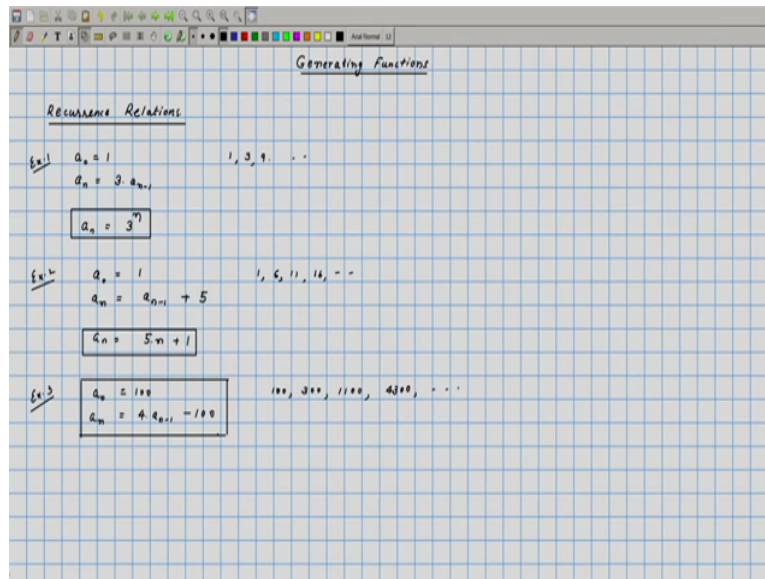

A gf. in a formal power series.

$$a_0, a_1, a_2, \dots \quad \{a_n\}_{n \geq 0} \quad \longmapsto \quad a_0 + a_1 x + a_2 x^2 + a_3 x^3 + \dots \quad a_n x^n + \dots$$

$a_n = n!$ $1 + x + 2x^2 + 6x^3 + 24x^4 + 120x^5 + \dots$

$1, 1, 1, \dots$ $a_n = 1$ $1 + x + x^2 + \dots = \frac{1}{1-x}$ ← G.F. for $\{1\}_{n \geq 0}$

$1, 2, 4, \dots$ $a_n = 2^n$ $1 + 2x + 4x^2 + \dots = \frac{1}{1-2x}$ ← G.F. for $\{2^n\}_{n \geq 0}$

So, let us see the basics of generating function, so what basically is a generating function. You can think of the following analogy you can think of it as a clothes line. So, let us say the starting point of the clothes line is known, okay, this is the infinite clothes line and the first number of the sequence is put at the first position, the second then a1 is attached somewhere, a2 is attached somewhere when immediately after a1 and then a3 is attached and so on.

The reason why we are thinking about the clothes line analogy is we could wrap around the clothes line, we could tangle it and then you could pass it on somebody else and all they need to do is to stretch the clothes line and look at its starting point and from the clothes line they can just read of the values of the sequence.

So, we have an infinite sequence and we can think of the generating function as a clothes line on which various values are held at specific position, more formally the mathematical way to think of this is as a formal power series. So, a generating function is a formal power series.

So, if you have a sequence, let us say a_0 followed by a_0 , a_1 , a_2 so on. So, in general let say a n, so given a sequence, the generating function corresponding to this is the sequence is the formal power series given by a_0 plus a_1x plus a_2x^2 plus a_3x^3 and so on.

So, a and x raise to n plus 1. So, given any sequence we can associate a formal power series with it. In case of some sequences the formal power series can be compressed and written in nice formats whereas for some other things the formal power series, it may not have a closed form expression.

For example, if your sequence was let us say the factorial sequence, so a_n is equal to n factorial, if you look at this sequence that is going to be $1 + x + 2x^2 + 6x^3 + 24x^4 + 120x^5$ and so on. So, it is difficult to imagine some place where this sequence or this particular power series can be thought of as converging to some particular value, but we will not bother about the convergence aspects. This expression is basically what we will call as the formal power series or the generating function corresponding to the sequence a_0, a_1, a_2 and so on.

So, let us take some more examples, if you look at let say the sequence $1, 1, 1$ so on. So, in other words a_n is equal to 1 corresponding to it the formal power series would be $1 + x + x^2 + \dots$ and so on. So, this if we assume x to be less than or equal to 1 over the absolute value of x to be less than or equal to 1 , we can just simply write it as $1/(1-x)$.

So, this you can think of it as it is rolling together the generating function into a simpler expression, okay. So, instead of telling the whole power series, we can just say that we are looking at the generating function $1/(1-x)$ when we were thinking about the sequence $1, 1, 1, 1$ and so on.

And if you had let us say the sequence $1, 2, 4, 8$ so on, so the n th term you can think of as 2^n , that will correspond to the sequence $1 + 2x + 4x^2 + \dots$ and so on and this we can think of it is the I mean if you assume suitable values for x , you can say that it will be $1/(1-2x)$, okay.

So, this is the generating function corresponding to 1 and this is the generating function for 2^n , n greater than 0 , okay. So, now that we have the definition of generating functions in place, we can think of how to solve this particular recurrence relation using generating functions, okay.

(Refer Slide Time: 09:01)

$$A(x) = a_0 + a_1 x + a_2 x^2 + \dots$$

$$a_0 = 100$$

$$a_n = 4a_{n-1} - 100 \quad (1)$$

$$a_n x^n = 4a_{n-1} x^n - 100 x^n \quad (2) \quad (\text{Multiply (1) by } x^n)$$

$$\sum_{n=1}^{\infty} a_n x^n = \sum_{n=1}^{\infty} 4a_{n-1} x^n - \sum_{n=1}^{\infty} 100 x^n$$

$$A(x) - a_0 = 4x \sum_{n=1}^{\infty} a_{n-1} x^{n-1} - 100 \sum_{n=1}^{\infty} x^n$$

$$4x A(x) - 100 x = \frac{100 x}{1-x}$$

$$A(x) - 100 = \frac{4x A(x) - 100 x}{1-x}$$

So, little bit about the notation, whenever we think of a sequence a_0, a_1, a_n its generating function we will denote by $A(x)$. So, $A(x)$ is equal to a_0 plus $a_1 x$ plus $a_2 x^2$ and so on.

So, now what we have is we have this following recurrence relation a_0 is equal to 100 and a_n is equal to 4 times a_{n-1} minus 100. Let us call this as equation 1, if we multiply both sides by x^n we will get $a_n x^n$ is equal to 4 times $a_{n-1} x^n$ minus 100 times x^n , okay, and then we will sum this equation 2 for values of n starting from 1 to infinity, okay.

So, both sides if we sum up the LHS and the RHS summation n is equal to 1 to infinity $a_n x^n$ is going to be equal to summation $4 a_{n-1} x^n$; n is again varying from 1 to infinity. The reason why we took n is equal to 1 to infinity instead of 0 to infinity is the term a_{n-1} would not have made sense when n is equal to 0, okay and furthermore this I mean in other words the equation 1, which we started off holds only for values of n greater than or equal to 1, okay.

So, n minus summation n is equal to 1 to infinity, $100 x^n$. So, if we look at look at this equation closely, we can see that some parts of these equations is starting to resemble $A(x)$, for example, the LHS term is almost the term on the LHS is almost equal to $A(x)$ just that the first term is missing.

So, this we can rewrite as so this is equal to $A(x) - a_0$ whereas the second term here, this is equal to if we take x outside and 4 outside, what we have is summation n is equal to 1 to

infinity a n minus 1 x raise to n minus 1. Now, since the n are starting from 1 so the first term of the summation is a0 x raise to 0, the next term is a 1 x raise to n and so on and so this will basically be equal to 4x ax, okay.

And the the last term on the LHS is summation n is equal to 1 to infinity, we can take 100 x outside and we will get x raise to n minus 1, okay, and that is going to be equal to minus 100x into the summation is 1 by 1 minus x, 2 as 100 we will get ax minus 100 is equal to 4x times ax minus 100x by 1 minus x.

So, whatever recurrence we had, we had used that to write a new equation involving the generating functions of the sequence. This we can rewrite as ax into 1 minus 4x is equal to 100 minus 100 x by 1 minus x and therefore ax is equal to 100 by 1 minus 4x minus 100x by 1 minus x into 1 minus 4x. So, now instead of thinking about the recurrence relation, we have generating function of x, which basically contains all the information corresponding to the sequence in a succinct form.

(Refer Slide Time: 13:50)

$$A(x) = \frac{100}{1-x} - \frac{100x}{(1-x)(1-4x)}$$
 ← Partial fraction to split the common denominator

Try to write $A(x) = a_0 + a_1x + a_2x^2 + \dots$

$$= 100(1 + 4x + (4x)^2 + \dots) - \left(\frac{a}{1-x} + \frac{b}{1-4x} \right)$$

$$\frac{100x}{(1-x)(1-4x)} = \frac{a}{1-x} + \frac{b}{1-4x}$$

Multiply both side by $(1-x)$ & substitute $x=1$

$$\frac{100x(1-x)}{(1-x)(1-4x)} = \frac{100}{-3} = a$$

$$b = \frac{100 \times \frac{1}{4}}{1 - \frac{1}{4}} = \frac{100}{3}$$

$$A(x) = 100(1 + 4x + (4x)^2 + \dots) + \frac{100}{3} \left(\frac{1}{1-x} - \frac{1}{1-4x} \right)$$

$$a_n = \text{coeff of } x^n \text{ in } A(x)$$

$$= 100 \times 4^n + \frac{100}{3} (1 - 4^n)$$

$$= \left(100 - \frac{100}{3}\right) 4^n + \frac{100}{3} = \frac{200}{3} 4^n + \frac{100}{3}$$

$$A(x) = a_0 + a_1 x + a_2 x^2 + \dots$$

$$a_0 = 100$$

$$a_n = 4a_{n-1} - 100 \quad (1)$$

$$a_n x^n = 4a_{n-1} x^n - 100 x^n \quad (2) \quad (\text{Multiply (1) by } x^n)$$

$$\sum_{n=1}^{\infty} a_n x^n = \sum_{n=1}^{\infty} 4a_{n-1} x^n - \sum_{n=1}^{\infty} 100 x^n$$

$$A(x) - a_0 = 4x \sum_{n=1}^{\infty} a_{n-1} x^{n-1} - 100 \sum_{n=1}^{\infty} x^n$$

$$4x A(x) - 100 x x = \frac{100 x x}{1-x}$$

$$A(x) - 100 = \frac{4x A(x) - 100 x x}{1-x}$$

So, what we know is ax is equal to 100 by 1 minus $4x$ minus $100x$ divided by 1 minus x into 1 minus $4x$. Now, from this, how do we get the value of the n th term? So, we can look at this generating function carefully and we can try to determine the x raise, the coefficient of x raise to n if you write this as a_0 plus if you were to write this as let us say $\alpha_0 x$ raise to 0 plus $\alpha_1 x$ raise to 1 and so on.

If you could write it in such a format and α_n must be equal to x raise to n , so try to write ax as α_0 plus $\alpha_1 x$ plus $\alpha_2 x$ square and so on, okay, so there are two terms 100 by 1 minus x we can simply write it as 100 by 1 plus $4x$ plus $4x$ whole square plus so on because 100 by 1 minus $4x$ is a sum of a geometric progression, if you think of 1 plus $4x$ plus $4x$ square and so on that is a geometric progression that will sum up to 1 by 1 minus $4x$.

And the next term is little more tricky, but we will use what is known as the partial fractions method. So, we will write this as, this is a by 1 minus x plus b by 1 minus $4x$, okay. If you write it in this format, this expression easily can be thought of as a geometric series and their expansion is easy to write, okay, so we want $100 x$ by 1 minus x into 1 minus $4x$ to be equal to a by 1 minus x plus b by 1 minus $4x$, okay.

Now, what are the values of a and b , which will make this equation true. We can multiply both sides by 1 minus x and substitute x is equal to 1 , that will give the value of a , so when you multiply that the left hand side will be $100x$ into 1 minus x by 1 minus x into 1 minus $4x$, these gets cancelled.

Now, when you substitute x equals 1 you will get 100 by 1 minus 4 , that is minus 3 , okay, and on the right hand side 1 minus x term cancels off with so 1 minus x terms will cancel off

whereas b by 1 minus 4x into 1 minus x when you put x equals 1, the 1 minus x term becomes 0 and hence the right hand side of this equation is going to be equal to a.

So, this 100 by minus 3 is going to be a and similarly if you multiply both sides by 1 minus 4x and put x is equal to 1 by 4 what you will get is the value of b. Therefore, we can write b is equal to 100 into 1 by 4 divided 1 minus 1 by 4, that is going to be 100 into 1 by 4 by 3 by 4 that is 100 by 3 and therefore we can simply write this generating function ax as 100 into 1 plus 4x plus 4x square so on minus 100 by 3 say plus 100 by 3 into 1 by 1 minus x minus 1 by 1 minus 4 x.

So, this can be written as so if you look at the nth term, so from this you can read off the nth term, so a n is equal to coefficient of x raise to n, that is going to be equal to 100 into 4 raise to n plus 100 by 3 into 1 by 1 minus x, the term was going to be 1 minus 1 by 1 minus 4x that is again will be minus 4 raise to n. So, this is going to be equal to 100 minus 100 by 3 into 4 raise to n plus 100 by 3, so the nth term is going to be 200 by 3 into 4 raise to n plus 100 by 3.

So, just for this particular case, we will verify that our answer is actually agreeing with generating function, I mean with the recurrence relation.

(Refer Slide Time: 19:06)

$$a_n = \frac{200 \cdot 4^n}{3} + \frac{100}{3}$$

Verify by ind.

$$a_1 = 100 = \left(\frac{200 \cdot 1 + 100}{3} \right) \quad (\text{ind. base case})$$

$$= 100$$

$$a_n = 4 a_{n-1} - 100$$

$$= 4 \left(\frac{200 \cdot 4^{n-1}}{3} + \frac{100}{3} \right) - 100$$

$$= \frac{200 \cdot 4^n}{3} + \frac{400}{3} - 100$$

$$= \frac{200 \cdot 4^n}{3} + \frac{100}{3}$$

$$A(x) = \frac{100}{1-x} - \frac{100x}{(1-x)(1-4x)} \quad \leftarrow \text{Partial fraction to split the common}$$

Try to write $A(x) = a_0 + a_1x + a_2x^2 + \dots$

$$= 100(1+x+(4x)^2 + \dots) = \left(\frac{a}{1-x} + \frac{b}{1-4x} \right)$$

$$\frac{100x}{(1-x)(1-4x)} = \frac{a}{1-x} + \frac{b}{1-4x}$$

Multiply both sides by $(1-x)$ & substitute $x=1$

$$\frac{100 \cdot (1-x)}{(1-x)(1-4x)} = \frac{100}{-3} = a$$

$$b = \frac{100 \cdot \frac{1}{4}}{1-\frac{1}{4}} = \frac{100}{3}$$

$$A(x) = 100(1+4x+(4x)^2 + \dots) + \frac{100}{3} \left(\frac{1}{1-x} - \frac{1}{1-4x} \right)$$

$$a_n = \text{coeff of } x^n \text{ in } A(x)$$

$$= 100 \cdot 4^n + \frac{100}{3} (1 - 4^n)$$

$$= \left(\frac{100 - 100}{3} \right) 4^n + \frac{100}{3} = \frac{200}{3} \cdot 4^n + \frac{100}{3}$$

$$A(x) = a_0 + a_1x + a_2x^2 + \dots$$

$$a_0 = 100$$

$$a_n = 4a_{n-1} - 100 \quad (1)$$

$$a_n x^n = 4a_{n-1} x^n - 100x^n \quad (2) \quad (\text{Multiply (1) by } x^n)$$

$$\sum_{n=1}^{\infty} a_n x^n = \sum_{n=1}^{\infty} 4a_{n-1} x^n - \sum_{n=1}^{\infty} 100x^n$$

$$\parallel \parallel$$

$$A(x) - a_0 = 4x \sum_{n=1}^{\infty} a_{n-1} x^{n-1} - 100 \sum_{n=1}^{\infty} x^n$$

$$\parallel$$

$$4x A(x) - 100x \cdot \frac{1}{1-x}$$

$$A(x) - 100 = 4x A(x) - \frac{100x}{1-x}$$

$$A(x)(1-x) = 100 - \frac{100x}{1-x}$$

$$\therefore A(x) = \frac{100}{1-4x} - \frac{100x}{(1-x)(1-4x)}$$

So, we got an is equal to 200 by 3 into 4 raise to n plus 100 by 3, we will verify by using induction, so if you look at a0, which is given to be 100 by the recurrence relation, if we substitute in formula, we will get 200 by 3 into 4 raise to 0, that is going to be 1 plus 100 by 3 that is 300 by 3 that is going to be equal to 100, okay.

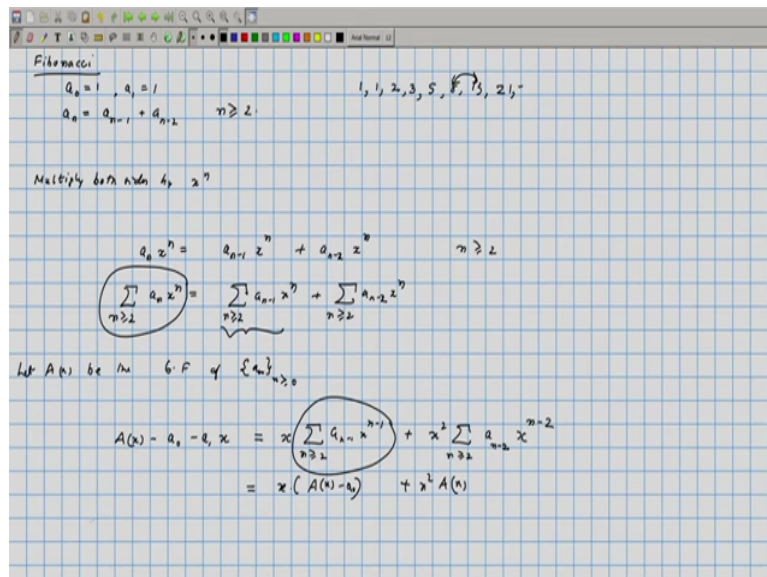

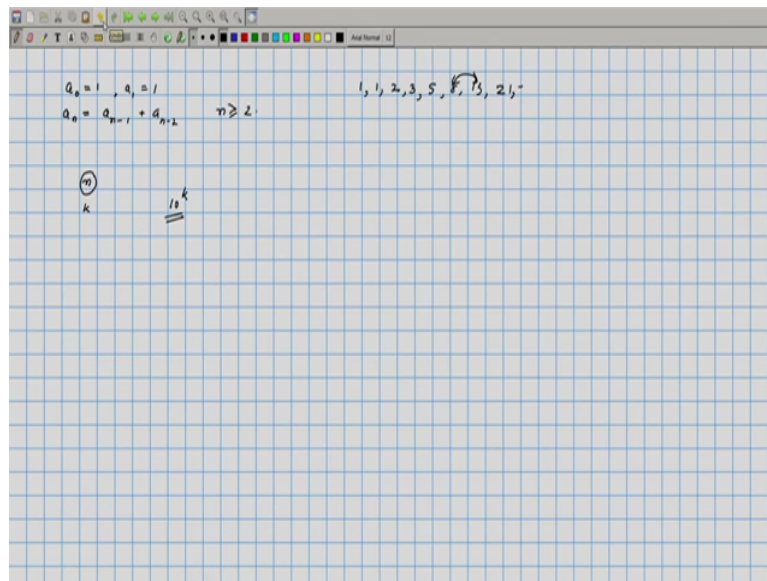

So, that is induction base case and we if we assume that the formula is true up to n minus 1 we need to check that a n is equal to 4 times a n minus 1 minus 100, so up to n minus 1 we will believe that expression was correct and therefore this is going to be equal to 4 into 200 by 3 into 4 raise to n minus 1 plus 100 by 3 minus 100.

The recurrence relation gives this is the answer and that is going to be equal to 200 by 3 into 4 raise to n plus 400 by 3 minus 100. So, that is going to be equal to 200 by 3 into 4 raise to n

plus 100 by 3 that agrees with the formula that we had computed via the generating function method.

So, we have seen the generating function method used to solve a particular recurrence relation. We will see one more recurrence relation just for practice slightly different from the one that we had seen. Here, we had just one term 4 times n minus 1 and there is a constant term.

(Refer Slide Time: 21:07)

So, we will look at a more famous recurrence relation namely the Fibonacci recurrence, so if we think about the Fibonacci sequence, the sequence is given as a_0 is equal to 1 and a_1 is equal to 1 and a_n is given by a_{n-1} plus a_{n-2} where n is greater than or equal to 2, okay.

So, the sequence if you write the first few terms, it is going to look like 1, 1 next term is the sum of these two 2, next term is going to be 3, 5, 8, 13 and so on, okay. So, add up the two terms their sum is the next term 21 and so on. So, we can find the n th term by just repeating this process, if you were to write a computer program to do this.

If n is input and if we want to write the n th term of the sequence, it is going to take a long time, it is going to take time, it is an exponential time algorithm because the input is given as n which is given in decimal, so this will have some k digits and the time taken is going to be proportional to n which is something like 10 raise to k .

So, if you just apply the recurrence relation we going to get an exponential time algorithm to compute the value of a_n or f_n here, the n th Fibonacci number. So, let us see how we can do this via generating functions. Method is identical to the one that we had looked at earlier, we look at the main recurrence relation, which says a_n is equal to a_{n-1} plus a_{n-2} .

So, multiply both sides by x raise to n , and we will get $a_n x$ raise to n is equal to $a_{n-1} x$ raise to n plus $a_{n-2} x$ raise to n , so this equation is valid only for n greater than or equal to 2. So, we sum this up for all values of n greater than or equal to 2, so sum over n greater than 2 $a_n x$ raise to n , that is going to be equal to the summation $a_{n-1} x$ raise to n , n greater than or equal to 2 plus summation n greater than or equal to 2 $a_{n-2} x$ raise to n , okay.

Now, the first term is going to be if you assume that ax , so let ax be the generating function, then the first term in this expression is going to be equal to ax , there are two terms missing namely a_0 and $a_1 x$, so this can be written as ax minus a_0 minus $a_1 x$.

This is going to be equal to the first summation in the right hand side. It resembles ax if you take an x outside, you will get this as summation n greater than or equal to 2, $a_{n-1} x$ raise to $n-1$, and the second term if we take x square outside this is going to be summation n greater than or equal to 2 $a_{n-2} x$ raise to $n-2$ and this is going to be equal to x times and the summation every term in generating function is present except, the when n equals 2 what you get is $A_1 x$ raise to 1, the next term is $a_2 x$ square, only term missing is A_0 .

So, this is going to be ax minus a_0 plus x square into here n starts from 2 and a_{n-2} is going to be 0 times x raise to 0 is $a_1 x$ raise to n , $a_1 x$ raise to 1 and so on, so this is going to be equal to ax . We can bring all the ax 's together and substitute the values for the constants a_0

and a_1 . So, look at the equations involving the generating functions and by rearranging terms and plugging in the value of a_0 and a_1 we will get the generating function as equal to $1/(1 - x - x^2)$.

(Refer Slide Time: 26:00)

The image shows a handwritten derivation on a grid background. It starts with the generating function $A(x) = \frac{1}{1-x-x^2}$. The goal is to determine the coefficient of x^n using the partial fraction method. The function is decomposed as $\frac{1}{1-x-x^2} = \frac{A}{\alpha-x} + \frac{B}{\beta+x}$. This is then written as $\frac{A\beta + B\alpha + Ax - Bx}{\alpha\beta + \alpha x - \beta x - x^2}$. Since the denominators are equal, the numerators must be equal: $A\beta + B\alpha + Ax - Bx = 1$. This leads to the system of equations: $A\beta = 1$, $A - B = 0$, and $A\alpha - B\beta = 0$. Solving these gives $\alpha = \frac{\sqrt{5}-1}{2}$ and $\beta = \frac{\sqrt{5}+1}{2}$. The coefficient of x^n is then found by summing the coefficients from each partial fraction: $\text{Coeff } x^n = \frac{A}{\alpha-x} + \frac{B}{\beta+x} = \frac{A}{\alpha} \left(\frac{1}{x}\right)^{n-1} + \frac{B}{\beta} \left(\frac{1}{-x}\right)^{n-1}$.

Now, what remains is to determine the coefficient of x^n , it is if we expand out this particular function $1/(1 - x - x^2)$ what will be the coefficient of x^n ? So, we will use the method of partial fractions. So, we will write $1/(1 - x - x^2)$ as $A/(alpha - x) + B/(beta + x)$, okay.

Now, A , B , α and β they have to satisfy some conditions in particular $Ax + 1$ means if you multiply them out, what you get is $A\beta + B\alpha + A\alpha x - B\beta x$ divided by $\alpha\beta + \alpha x - \beta x - x^2$. So, comparing the terms we will get $A = B$ because $A\alpha x - B\beta x$ should be 0 because there is no coefficient for x in the numerator.

So, $A = B$, and therefore we can simply write this is this is equal to $A/(\alpha - x) + A/(\beta + x)$ where α and β has to satisfy additional conditions by comparing the coefficients we will get $\alpha\beta = 1$ and $\alpha - \beta = -1$.

So, those will be the roots of this particular denominator polynomial, therefore α will be equal to $(\sqrt{5}-1)/2$ and β will be equal to $(\sqrt{5}+1)/2$, okay. Now, if we plug in these values we can compute the coefficient of x^n , okay.

So, the coefficient of x raise to n will be the coefficient of x raise to n in A by α minus x plus coefficient of x raise to n in B by β plus x and this is equal to A by α into 1 by α raise to n minus 1 and for the other term the coefficient will be B by β that is going to be B is same as A so that is A by β into 1 by minus β because here the term is β plus x minus β raise to n minus 1 .

(Refer Slide Time: 29:48)

$$\frac{1}{1-x-x^2} = \frac{A}{\alpha-x} + \frac{B}{\beta+x} = \frac{A\beta + B\alpha}{\alpha\beta + \alpha x - \beta x - x^2}$$

$$A = B \implies \frac{A}{\alpha-x} + \frac{A}{\beta+x}$$

$$\alpha\beta = 1, \alpha - \beta = -1$$

$$\alpha = \frac{\sqrt{5}-1}{2} < 1, \beta = \frac{\sqrt{5}+1}{2} > 1$$

$$\text{Coeff } x^n = \text{Coeff } x^n \text{ in } \frac{A}{\alpha-x} + \frac{B}{\beta+x} = \frac{A}{\alpha} \left(\frac{1}{\alpha}\right)^{n-1} + \frac{B}{\beta} \left(\frac{1}{-\beta}\right)^{n-1}$$

$$= \frac{1}{\sqrt{5}} \left(\frac{1}{\alpha^n} - \frac{1}{(-\beta)^n} \right)$$

$$= \frac{1}{\sqrt{5}} \left(\beta^n - (-\alpha)^n \right)$$

$$\frac{1}{1-x-x^2} = \frac{A}{\alpha-x} + \frac{B}{\beta+x} = \frac{A\beta + B\alpha}{\alpha\beta + \alpha x - \beta x - x^2}$$

$$A = B \implies \frac{A}{\alpha-x} + \frac{A}{\beta+x}$$

$$\alpha\beta = 1, \alpha - \beta = -1$$

$$\alpha = \frac{\sqrt{5}-1}{2} < 1, \beta = \frac{\sqrt{5}+1}{2} > 1$$

$$\text{Coeff } x^n = \text{Coeff } x^n \text{ in } \frac{A}{\alpha-x} + \frac{B}{\beta+x} = \frac{A}{\alpha} \left(\frac{1}{\alpha}\right)^{n-1} + \frac{B}{\beta} \left(\frac{1}{-\beta}\right)^{n-1}$$

$$= \frac{1}{\sqrt{5}} \left(\frac{1}{\alpha^n} - \frac{1}{(-\beta)^n} \right)$$

$$= \frac{1}{\sqrt{5}} \left(\beta^n - (-\alpha)^n \right)$$

And we can further infer the value of A by observing that A times α plus β that is this particular term that should be equal to 1 , so A is equal to 1 by α plus β and α plus β is equal to $\sqrt{5}$, so 1 by $\sqrt{5}$ that is A times 1 by minus β raise to n .

We know that α and β are inverses of each other so this can be written as 1 by $\sqrt{5}$ into β raised to n minus 1 by α raised to n , okay, because 1 by β is $-\alpha$, and

observe that beta is a quantity, which is greater than 1 and alpha is a quantity whose absolute value is less than 1 because root 5 minus 1 by 2 you can show that this is going to be less than.

So, the dominant term is going to be beta raise to n, so although both these numbers alpha and beta are irrational numbers they will the irrational part will cancel out with each other and if you want an approximation, okay, you can even ignore the part alpha raise to n after a certain point because alpha being less than 1 it will quickly go towards 0 and if you just round off whatever is the integer part of beta raise to n, if you round off to the nearest integer, you will get the correct answer the exact answer without any approximations.

Now, we were counting some combinatorial object namely the we were estimating the Fibonacci the nth Fibonacci number we saw that the strings numbers alpha and beta are coming in.

Linear Algebraic Formulation

$$X_n = \begin{pmatrix} f_n \\ f_{n+1} \end{pmatrix} = \begin{pmatrix} f_{n-1} + f_{n-2} \\ f_{n-1} \end{pmatrix} = \underbrace{\begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix}}_A \begin{pmatrix} f_{n-1} \\ f_{n-2} \end{pmatrix}$$

$$X_n = A \cdot X_{n-1}$$

$$\Rightarrow X_{n+1} = A X_n$$

$$X_{n+1} = P D^n P^{-1} X_1$$

$$A = P D P^{-1}$$

$$A^n = P D^n P^{-1}$$

$$\lambda_1 \quad \lambda_2$$

$$(A \lambda_1^n + B \lambda_2^n)$$

$$A(x) = \frac{1}{1-x-x^2}$$
 Determine the Coeff of x^n
 Partial fractions method

$$\frac{1}{1-x-x^2} = \frac{A}{\alpha-x} + \frac{B}{\beta+x} = \frac{A\beta + B\alpha + A\alpha - B\beta}{\alpha\beta + \alpha x - \beta x - x^2}$$

$$A = B = \frac{1}{\alpha-x} + \frac{1}{\beta+x}$$

$$\alpha\beta = 1$$

$$\alpha - \beta = -1$$

$$\alpha = \frac{\sqrt{5}-1}{2} < 1$$

$$\beta = \frac{\sqrt{5}+1}{2} > 1$$

$$\text{Coeff } x^n = \text{Coeff } x^n \text{ so } \frac{A}{\alpha-x} = \frac{A}{\alpha} \left(\frac{1}{\alpha}\right)^{n-1}$$

$$+ \frac{B}{\beta+x} = \frac{A}{\beta} \left(\frac{1}{-\beta}\right)^{n-1}$$

$$= \frac{1}{\sqrt{5}} \left(\frac{1}{\alpha^n} - \frac{1}{(-\beta)^n} \right)$$

$$\frac{1}{1-x-x^2} = \frac{A}{\alpha-x} + \frac{B}{\beta+x} = \frac{A\beta + B\alpha + A\alpha - B\beta}{\alpha\beta + \alpha x - \beta x - x^2}$$

$$A = B = \frac{1}{\alpha-x} + \frac{1}{\beta+x}$$

$$\alpha\beta = 1$$

$$\alpha - \beta = -1$$

$$\alpha = \frac{\sqrt{5}-1}{2} < 1$$

$$\beta = \frac{\sqrt{5}+1}{2} > 1$$

$$\text{Coeff } x^n = \text{Coeff } x^n \text{ so } \frac{A}{\alpha-x} = \frac{A}{\alpha} \left(\frac{1}{\alpha}\right)^{n-1}$$

$$+ \frac{B}{\beta+x} = \frac{A}{\beta} \left(\frac{1}{-\beta}\right)^{n-1}$$

$$= \frac{1}{\sqrt{5}} \left(\frac{1}{\alpha^n} - \frac{1}{(-\beta)^n} \right)$$

We can also see that the same thing arises in another way as well. So, let us look at the linear algebraic formulation. So, now instead of thinking of one particular Fibonacci number, instead of thinking of the nth Fibonacci number, we will think of a vector x_n which denotes the pair of Fibonacci number namely f_n and f_{n-1} .

So, this pair is what we will denote by a vector of size 2 and note that this vector will be equal to f_{n-1} plus f_{n-2} and f_{n-1} will be just define minus 1 and therefore this can be written as (f_{n-1}, f_{n-2}) because you can say that this matrix A multiplied by this particular vector will give you f_n, f_{n-1} , okay.

So, we can simply write this as $x_n = A x_{n-1}$ and therefore you can repeatedly apply this and say that $x_n = A^n x_1$, let us think of $x_1 = (1, 1)$, so $x_n = A^n x_1$ is equal to A^n raised to n times x_1 , okay. So, A^n is going to be a matrix is going to

be a 2 cross 2 matrix, if we can somehow estimate that matrix from that information, we can determine the n th Fibonacci number.

Now, in order to determine the n th Fibonacci, I mean the n th power of this matrix, we can diagonalize it, so suppose we can write A as PDP^{-1} then A^n is going to be equal to $P D^n P^{-1}$ and then we can write x_{n+1} is equal to $P^{-1} D^n P x_1$, okay.

And D is now going to be a diagonal matrix and this diagonal matrix it is diagonal values if it is, λ_1 and λ_2 this entire expression will basically be something of the form $A \lambda_1^n + B \lambda_2^n$, of course A and B are not going to be the same A and B from there but it is going to be something which is dependent on what the $P D$ etc, okay.

But you can see that the λ_1 and λ_2 which comes here will be equal to will be the same as what we saw earlier, in fact it will be our α and β and the coefficients will be $1/\sqrt{5}$, okay. We will stop here and learn more about generating functions in the next lecture.
