Lecture 34
Solution of Congruences

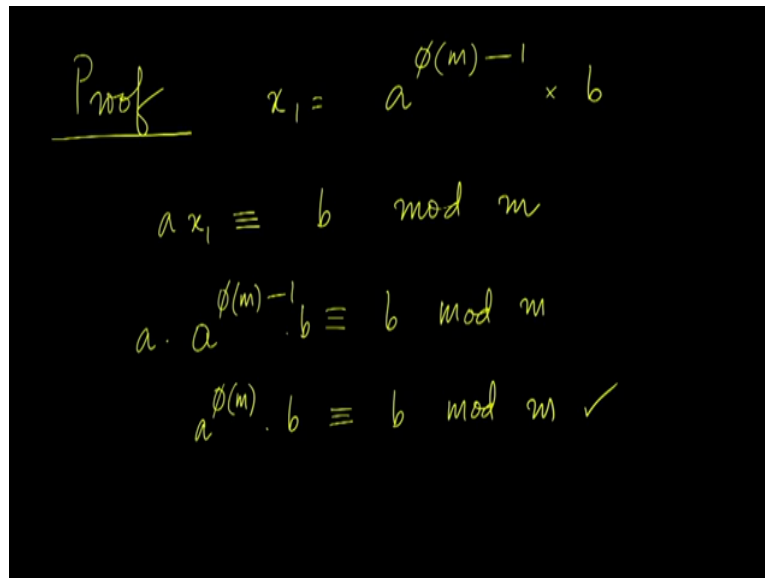

Welcome to the NPTEL mock on discrete mathematics this is the fifth lecture on number theory.

(Refer Slide Time: 00:40)

So let us begin with the theorem this is called theorem 5.1 let a say GCD of a and m is 1 then the congruence $ax \equiv b \pmod{m}$ has a solution x_1 more over all solutions are given by $x \equiv x_1 \pmod{m}$ equals x_1 plus jm where, j is an integer. In other words, there is a solution x_1 and every other solution is congruent to x_1 modulo m . So that is what the theorem states.

(Refer Slide Time: 01:51)

The image shows a handwritten mathematical proof on a black background. The word "Proof" is written in yellow and underlined. The first line is the equation $x_1 = a^{\phi(m)-1} \times b$. The second line is the congruence $a x_1 \equiv b \pmod{m}$. The third line is $a \cdot a^{\phi(m)-1} \cdot b \equiv b \pmod{m}$. The fourth line is $a^{\phi(m)} \cdot b \equiv b \pmod{m}$ with a checkmark at the end.

So let us proof the theorem, the theorem follows from the generalization of Fermats theorem let us say x_1 is a power ϕ of m minus 1 times b where, ϕ of m is the totient of m then plugin x_1 into the congruence we have the congruence says $a x_1 \equiv b \pmod{m}$, then we have a times a power ϕ of m minus 1, is congruent to this times b is congruence to $b \pmod{m}$ if x_1 is indeed a solution so let us check.

We find that a power ϕ of m times b is indeed a solution because by the generalization of Fermats theorem a power ϕ of m is $1 \pmod{m}$ so 1 into b is indeed $b \pmod{m}$. So the congruence is satisfied so if you plugin x_1 as a power ϕ of m times b the congruence holds good, so x_1 is indeed a solution of the congruence.

(Refer Slide Time: 03:26)

$$\begin{aligned}x &= x_1 + jm \text{ for some } j \in \mathbb{Z} \\ax &= ax_1 + a(jm) \\&\equiv b \pmod{m} \\ \text{So } x &\text{ is a solution}\end{aligned}$$

Let x equal to x_1 plus j into m for some j which is an integer, plugin this x in we find that ax is equals ax_1 plus a into jm this is congruent to $b \pmod{m}$ so x is also a solution. So all numbers that are congruent to x_1 modulo m of solutions. But, are this the only solutions,

(Refer Slide Time: 4:21)

$$\begin{aligned}\text{If } y &\text{ is a solution} \\ay - ax_1 &\equiv b - b \equiv 0 \pmod{m} \\a(y - x_1) &\equiv 0 \pmod{m} \\m \mid a(y - x_1) &\Rightarrow m \mid y - x_1 \\ \Rightarrow y &\equiv x_1 \pmod{m}\end{aligned}$$

Suppose y is some solution if y is a solution, then ay minus ax_1 is congruent to b minus b which is congruent to $0 \pmod{m}$. y is a solution, so ay is congruent to $b \pmod{m}$ x_1 is a solution, so ax_1 is $b \pmod{m}$ therefore, when you subtract we have a times y minus x_1 is $0 \pmod{m}$. or in other words m divides a times y minus x_1 but, since, a and m are relatively prime they do not have a common factor therefore it must be that m divides y minus x_1 which means y is congruent to x_1 modulo m .

(Refer Slide Time: 05:26)

$$\Rightarrow y: x_1 + jm \text{ for some } j \in \mathbb{Z}$$

Or in other words y is equal to x_1 plus jm for some j which is an integer, therefore we know that every solution of the congruence is congruent to x_1 modulo m and these are the only solutions. So let us consider one example.

(Refer Slide Time: 05:48)

Example

$$353x \equiv 254 \pmod{400}$$
$$\text{GCD}(353, 400) = 1$$
$$\phi(400) = 160$$

Let us say this is what we want to solve, $353x \equiv 254 \pmod{400}$, 353 is a prime so GCD of 353 and 400 is 1, and we also know that $\phi(400)$ is 160. We will see a close form expression for ϕ later on, so from that we will be able to calculate ϕ but a manual verification will in any case show that $\phi(400)$ is 160.

squared is congruent to 161 this is congruent to this expression but we have already seen that 161 squared is congruent to 321 and we know that 321 squared is congruent to 241 and $(12:16)$ 241 into 81 240 into 80 is $0 \pmod{400}$ so we need not count that so this is 321 once again. Which can be written as 200 plus 9 into 320 plus 1 which is minus 47 into 200 plus 320 is a multiple of 400 therefore that does not feature in the answer and 9 into 1 is 9 so we have 9 into 320 plus 200 which comes to 289. So the expression now reduces to minus 47 into 289.

(Refer Slide Time: 13:13)

$$\begin{aligned} &\equiv (300 - 11) - 47 \pmod{400} \\ &\equiv -14100 + 517 \pmod{400} \\ &\equiv -100 + 517 \pmod{400} \\ &\equiv 17 \pmod{400} \\ 353^{159} \times 254 &\equiv 17 \times 254 \pmod{400} \\ &\equiv 318 \pmod{400} \end{aligned}$$

289 is 300 minus 11 that into minus 47 is minus 14100 plus 517, 11 into 47 is 517 300 into 47 is 14100, but 14100 is minus 100 modulo 400 all this is modulo 400 so we have but, 517 is 117 mod 400 so this is 17 mod 400. Which is 353 power 159 but, what we need to find is 17 into 254 so thus, 353 power 159 into 254 is 17 into 254 mod 400 which you can verify is 318 mod 400.

(Refer Slide Time: 14:39)

318 is a solution for

$$353x \equiv 254 \pmod{400}.$$

All solutions are $\equiv 318 \pmod{400}$

$318 \in [0, 399]$ is the only solution

So 318 is a solution for $353x \equiv 254 \pmod{400}$, and we know that all solutions to this congruence are congruent to 318 mod 400, in other words 318 intersect 0 to 399 is the only solution, in the integral 0 to 399 318 is the only solution.

(Refer Slide Time: 15:30)

$-882 \quad -482 \quad -82 \quad 318 \quad 718 \quad 1118 \quad 1518$

\longleftrightarrow

$\equiv 318 \pmod{400}$

$ax \equiv b \pmod{m}$

$\left. \begin{array}{l} \\ \text{GCD}(a, m) = 1 \end{array} \right\} \underline{353}^{159}$

The other solutions are obtained by moving forward and backward at modulo m . So 718 1118 1518 are all solutions moving backwards 318 minus 400 would be minus 80 to minus 480 to minus 882 these are also solutions. So there is an infinite numbers solution but all solutions are congruent to 318 modulo 400. So this is one way of finding solutions for congruences of the form ax is congruent to $b \pmod{m}$, with GCD of am equal to 1, but it involves finding exponents of this form which is a long interious process so this is not exactly practical.

(Refer Slide Time: 16:40)

Theorem 2 (Wilson's Theorem)

If p is a prime, then

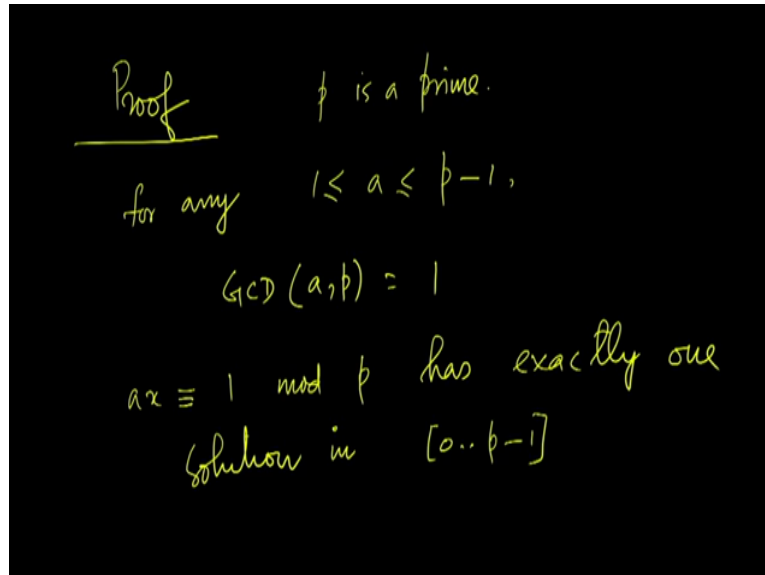

$(p-1)! \equiv -1 \pmod{p}$

or, $(p-1)! + 1 \equiv 0 \pmod{p}$

We will see an easier method later on the lecture now, let us see another theorem which is called Wilsons theorem what Wilsons theorem asserts is this p is a prime then p minus 1

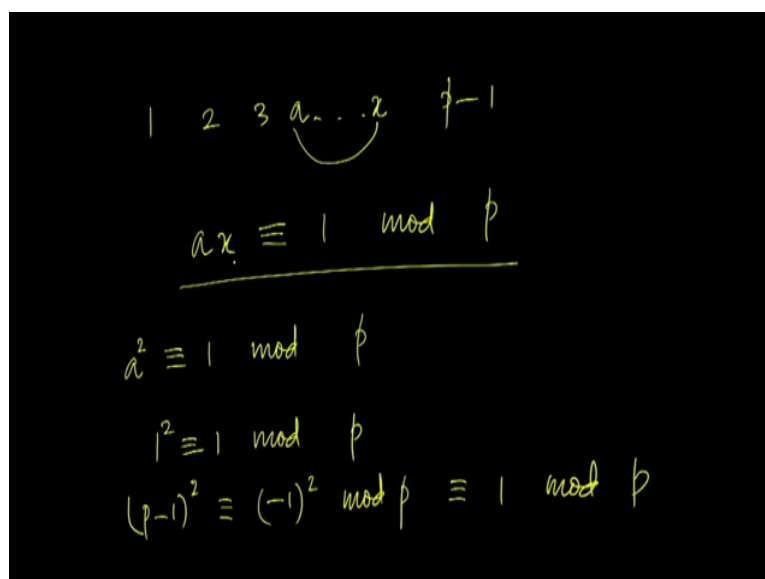

factorial is minus 1 mod p or in other words p minus 1 factorial plus 1 is divisible by p. so let us proof this theorem.

(Refer Slide Time: 17:30)

The proof goes like this for any a with a varying from 1 to p minus 1 where p is a prime we assume that p is a prime, then for any a in the range 1 to p minus 1 GCD of a, p equal to 1, a and p do not have any common factor, a prime does not have a common factor with any non-negative integer any positive integer less than that. So ax equals 1 mod p has exactly one solution in the interval 0 to p minus 1 this is what we have seen in theorem 1, ax equals 1 mod p has exactly one solution here we have taken b as 1 and m as p.

(Refer Slide Time: 18:49)

So if you consider the integers 1 to p minus 1 in this sequence we have a and the solution x of ax equals to $1 \pmod p$. So we can think of a and x is being paired of we want to consider a and x so that ax equal to $1 \pmod p$, but then could a and x be the same if a and x are the same we have a squared equals to $1 \pmod p$ there are two a 's which satisfy this for example 1 squared is $1 \pmod p$, p minus 1 the whole square is minus 1 to whole square mod p which is $1 \pmod p$. So in this we find that 1 and p minus 1 pair with themselves there is 1 into 1 is $1 \pmod p$ now a day's p minus 1 into p minus 1 is $1 \pmod p$.

(Refer Slide Time: 20:01)

$$\begin{aligned}
 a &\in 2 \text{ to } p-2 \\
 \text{then } \text{GCD}(a-1, p) &= 1 \\
 \text{GCD}(a+1, p) &= 1 \\
 (a-1)(a+1) &\equiv 1 \pmod p \\
 a^2 - 1 &\equiv 1 \pmod p \\
 \underline{a^2} &\not\equiv 1 \pmod p
 \end{aligned}$$

But what about the remaining if you consider the numbers in the range 2 to p minus 2 if a is in this range 2 to p minus 2 then we know that GCD of a minus 1 p is 1, p is a prime similarly, GCD of a plus 1 and p is also 1. A plus 1 can be at most p minus 1, therefore a minus 1 and a plus 1 are both relatively prime to p a minus 1 and a plus 1 therefore must be congruent to $1 \pmod p$ which means a squared minus 1 is $1 \pmod p$ or a squared is not congruent to $1 \pmod p$, therefore no a within the range 2 to p minus 2 we will have this property a squared will not be $1 \pmod p$ and here we were seeking all the a 's so that a squared is $1 \pmod p$ we found that 1 squared is $1 \pmod p$ and p minus 1 the whole squared also $1 \pmod p$ so 1 and p minus 1 do pair with themselves.

(Refer Slide Time: 21:48)

$$1 \quad 2 \quad 3 \quad \dots \quad p-2 \quad p-1$$

a pair with $x \neq a$ so that

$$ax \equiv 1 \pmod{p}$$
$$1 \cdot 2 \cdot \dots \cdot (p-2) \cdot (p-1) \equiv 1 \cdot (p-1) \pmod{p}$$

But, then if you consider the other numbers in the range 2 to p minus 2 we find that this do not pair with themselves so there they pair with some other so any a here will pair with x not equal to a so that ax equal to 1 mod p. Now let us consider this product p minus 1 factorial, consider the integers in the range 2 to p minus 2 we know that all of them pair with each other for every a in this range there is an x within this range that is not equal to a so that ax equal to 1 mod p, therefore the product of all these together is 1 mod p therefore this entire product which is p minus 1 factorial can be written as 1 into p minus 1 mod p.

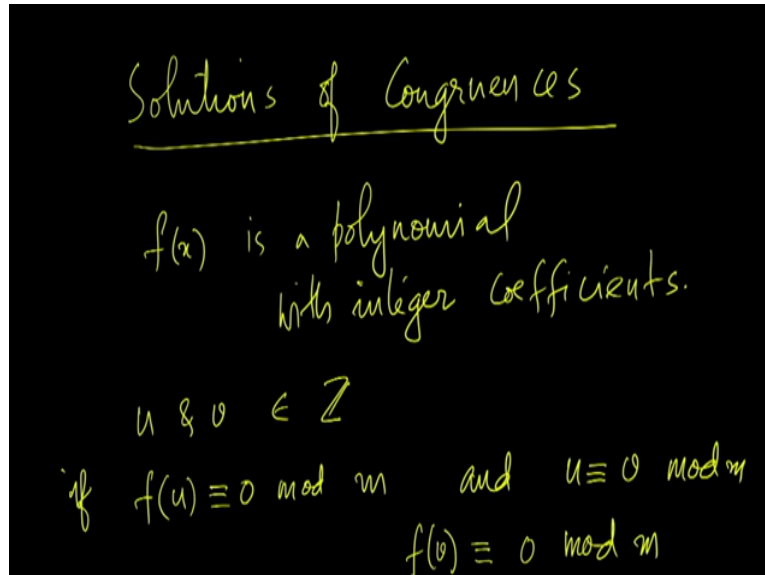

(Refer Slide Time: 23:06)

$$(p-1)! \equiv (p-1) \pmod{p}$$
$$\equiv -1 \pmod{p}$$
$$(p-1)! + 1 \equiv 0 \pmod{p}$$
$$p \mid (p-1)! + 1$$

Or in other words p minus 1 factorial, is p minus 1 mod p but p minus 1 is minus 1 mod p moving minus 1 to this side, we have p minus 1 factorial plus 1 is 0 mod p or p divides p

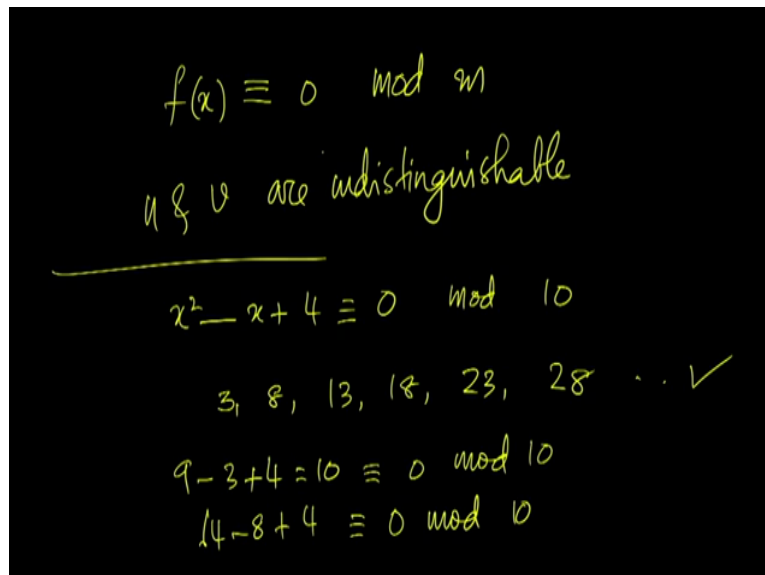

minus 1 factorial plus 1 which is what the theorem asserts Wilson's theorem asserts that p minus 1 factorial is minus 1 mod p .

(Refer Slide Time: 23:53)

Now, let us talk about solutions of congruences, suppose f of x is a polynomial with integer coefficients let us say u and v are integers if f of u is congruent to 0 mod m and u is congruent to v mod m you can readily verify that f of v is congruent to 0 mod m .

(Refer Slide Time: 24:56)

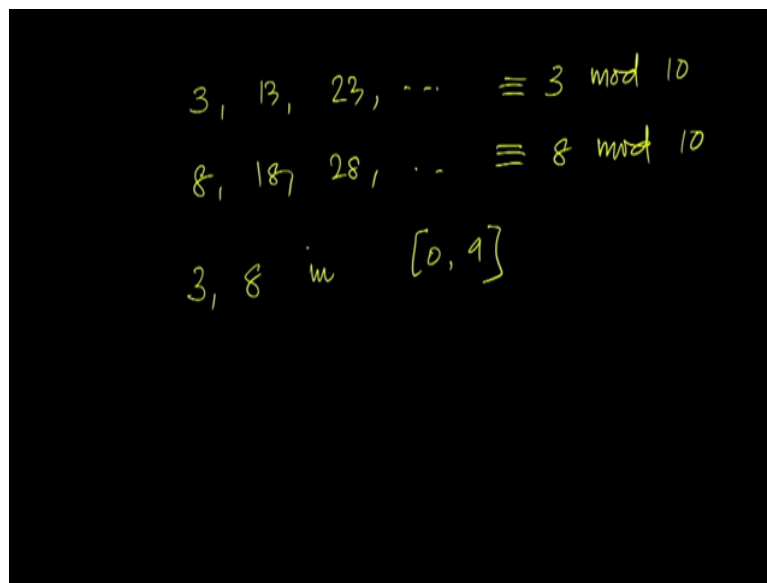

Therefore, when we talk about solutions of the congruence f of x congruent is 0 mod m we assume that u and v are indistinguishable they are congruent to each other mod m so we essentially assume that they are same solutions so we do not count them as separate solutions

modulo m . For example, consider $x^2 - x + 4 \equiv 0 \pmod{10}$, its solutions are this is congruent to 0 mod let us say 10 it's solutions are 3, 8, 13, 18, 23, 28, etc.

For example, substituting 3 in this we have $9 - 3 + 4 = 10$ this is 0 mod 10, substituting 8 here we have $64 - 8 + 4 = 60$ which is again 0 mod 10 so, these are all solutions. And you can also verify that if x is a solution then $x + 10$ is also a solution.

(Refer Slide Time: 26:23)

Handwritten mathematical notes on a black background:

$$3, 13, 23, \dots \equiv 3 \pmod{10}$$
$$8, 18, 28, \dots \equiv 8 \pmod{10}$$
$$3, 8 \text{ in } [0, 9]$$

But then, 3, 13, 23, these are all congruent to 3 mod 10, similarly 8, 18, 28, these are all congruent to 8 mod 10. Therefore, we do not consider them distinct solutions we say that we have only two solutions in 0 to 9 that is we have only two solutions modulo 10 for this congruence.

(Refer Slide Time: 26:56)

In general,
 if S is a CRS mod m
 then $|\{u \mid (f(u) \equiv 0 \pmod{m}) \wedge u \in S\}|$
 is the number of solns modulo m
 for $f(x) \equiv 0 \pmod{m}$

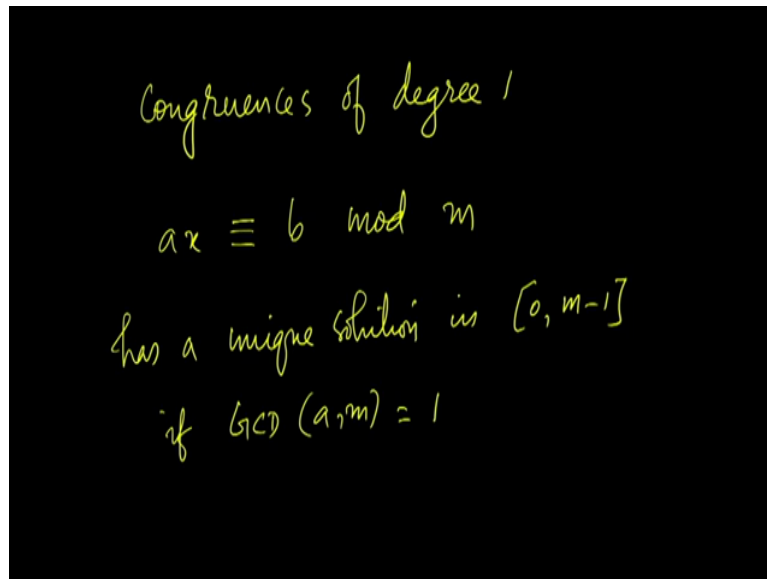

In general, if S is a complete residue system modulo m , then every u such that $f(u) \equiv 0 \pmod{m}$, and u belongs to S such u are what we consider solutions so the size of this set is the number of solutions, modulo m for $f(x) \equiv 0 \pmod{m}$ so we say that this congruence has these many solutions so within the CRS we consider all u that satisfy the congruence and the number of them is the number of solutions that we say the congruence has.

(Refer Slide Time: 28:22)

$f(x) = a_n x^n + a_{n-1} x^{n-1} + \dots + a_0$
 say, j is the largest integer
 so that $a_j \neq 0$
 then j is the degree of $f(x)$

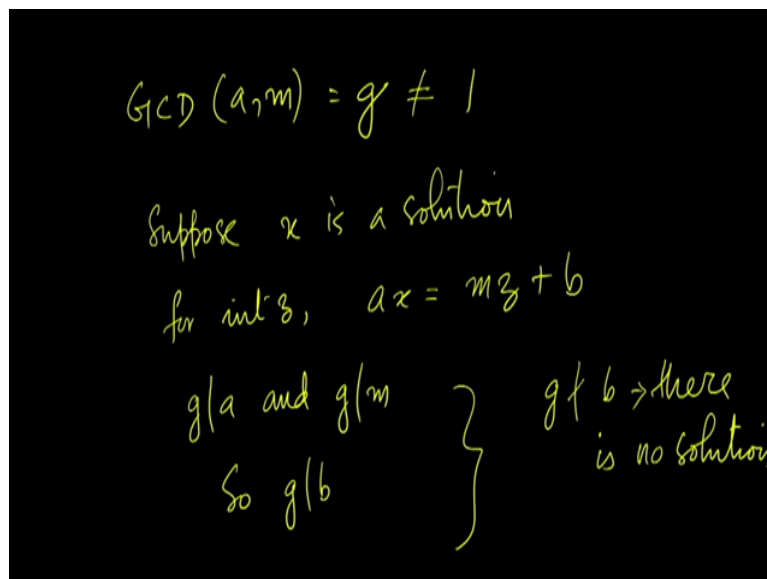

When we consider the polynomial of this form, say, j is the largest integer so that a_j is not equal to 0, then j is the degree of this polynomial.

(Refer Slide Time: 29:04)

So let consider the congruences of degree 1, there is a congruence of the form ax equals b mod m so by the first theorem of today we showed that this has a solution, this has a unique solution in 0 to m minus 1 in the interval 0 to m minus 1 if GCD of a , m equal to 1 .

(Refer Slide Time: 29:50)

But now, let us assume that GCD of a , m is small g which is not equal to 1 , so a and m have common factors, suppose x is a solution of the congruence ax congruent to b mod m then for integers z so some integer z ax equals mz plus b as ax is congruent to b modulo m ax must be b plus mz so some integer z now g is the GCD of a and m so g divides a and g divides m .

Therefore, g must divide b , in other words of the after finding the GCD of a and m we find that g does not divide b , then there is no solution, once again the argument is if GCD of a , m is g which is not equal to 1 , and the congruence has a solution x then ax must be mz plus b

for some integer z since, g divides a and g divides m g must divide b to, conversely if g does not divide b , there can be no solution.

(Refer Slide Time: 31:36)

$$\text{If } g|b \text{ then}$$
$$ax \equiv b \pmod{m}$$
$$\frac{a}{g}x \equiv \frac{b}{g} \pmod{\frac{m}{g}}$$

enough to solve this

So let us assume that g divides b if g divides b then ax congruent to $b \pmod{m}$ can be simplified g is a common factor of a , b and m in fact it is the GCD of a and m so dividing by g , I can rewrite this congruence in this fashion a by g x is congruent to b by $g \pmod{m}$ by g but the theorem that we saw in the previous lecture so, it is enough to solve this congruence.

(Refer Slide Time: 32:25)

$$\frac{a}{g}x \equiv 1 \pmod{\frac{m}{g}}$$

as $\text{GCD}\left(\frac{a}{g}, \frac{m}{g}\right) = 1$

Touch On

has exactly one solution in $\left[0, \frac{m}{g} - 1\right]$

Say, x_0 is that solution

So solve this congruence first let us consider a by g x is $1 \pmod{m}$ by g we know that GCD of a by g , m by g is 1 , they are relatively prime GCD of a and m is g so when you divide both a and m by g then the resulting numbers are relatively prime to each other, GCD of a by g , m by g is 1 , so this has this congruence has exactly one solution in which interval, 0 to m by g

minus 1, in this range this congruence has exactly one solution say, x_0 is that solution, so x_0 is a solution of $ax \equiv b \pmod{m}$, x_0 congruent to 1 mod m by g .

(Refer Slide Time: 33:37)

$$x_0 \cdot \frac{b}{g} \longrightarrow \text{is soln of}$$

$$\frac{a}{g} x \equiv \frac{b}{g} \pmod{\frac{m}{g}}$$

$$\left(\frac{a}{g} x_0\right) \frac{b}{g} \equiv \frac{b}{g} \pmod{\frac{m}{g}}$$

Then let us consider x_0 times b by g and substitute this in the original congruence which is ax congruent to b by g , congruent to b by $g \pmod{m}$, \pmod{m} by g . So we find that a by g , times x_0 because b by g is congruent to b by $g \pmod{m}$, \pmod{m} by g . So this is b by $g \pmod{m}$ by g , therefore x_0 times b by g is a solution of $ax \equiv b \pmod{m}$, x_0 solution of this congruence.

(Refer Slide Time: 34:54)

$$\left[0, \frac{m}{g} - 1\right]$$

$$\underline{\underline{x_0 + t \cdot \frac{m}{g}}}$$

$$\left[0, m-1\right] \longrightarrow \text{are solutions of}$$

$$ax \equiv b \pmod{m}$$

So this is the only solution of that congruence in 0 to m by g minus 1 and every solution to that congruence would be x naught plus t times m by g, consider all congruences of this form in the interval 0 to m minus 1 there all solutions of a ax equals b mod m so ax equals b mod m has multiple solutions in the range 0 to m minus 1 and although solutions can be found this way. There is but, the GCD of a and m is not 1 there are multiple solutions for this congruence in the interval 0 to m minus 1. So let us consider our previous example once again.

(Refer Slide Time: 35:58)

Example

$$353x \equiv 254 \pmod{400}$$

$$\text{GCD}(353, 400) = 1$$

$$1 = 17 \times 353 - 15 \times 400$$

17 is a soln for $353x \equiv 1 \pmod{400}$
in $[0, 399]$

Where we want to solve $353x \equiv 254 \pmod{400}$, we know that GCD of 353 and 400 is 1. 353 is in fact a prime therefore one can be expressed as a linear combination of 353 and 400 using Euclid's algorithm we find that 1 is 17 into 353 minus 15 into 400, taking modulo 400 on both sides we have a that 17 is a solution for $353x \equiv 1 \pmod{400}$. In other words, 17 is the only solution for this congruence in 0 to 399 but what we want to say solutions for 353 times x is congruent to 254 mod 400 instead of 1 so if you multiply this solution with 254.

(Refer Slide Time: 37:28)

$$17x \equiv 254 \pmod{400}$$
$$17 \times 254 = 4318 \equiv 318 \pmod{400}$$

318 is a solution for

$$353x \equiv 254 \pmod{400}$$

Which means 17 into 254 which is 4318 so is congruent to 318 mod 400. We find that 318 is a solution for the original congruence $353x \equiv 254 \pmod{400}$. So here we have managed to find the solution without resorting to large exponents.

(Refer Slide Time: 38:05)

Example

$$15x \equiv 25 \pmod{35}$$
$$ax \equiv b \pmod{m}$$
$$\text{GCD}(15, 35) \overset{\text{Touch On}}{= 5}$$
$$\underline{3x \equiv 5 \pmod{7}}$$

Let us consider one more example, let us see we want to solve this congruence $15x \equiv 25 \pmod{35}$ so this is of the form $ax \equiv b \pmod{m}$ where, a and m are not relatively prime. GCD of 15 and 35 is 5. Therefore, it is enough to solve the congruence obtained by dividing this by 5, so a by g is 3, so we have $3x \equiv 5 \pmod{7}$. So let us solve $3x \equiv 5 \pmod{7}$.

(Refer Slide Time: 39:00)

Consider,
 $3x \equiv 1 \pmod{7}$
 $\text{GCD}(3, 7) = 1$
 $1 = \underline{7} + 3x(-2)$
So -2 is a soln for $3x \equiv 1 \pmod{7}$
 $-2 \equiv 5 \pmod{7}$

To solve this first consider, $3x$ is congruent to $1 \pmod{7}$ so let us solve this first GCD of 3 and 7 is 1 therefore 1 can be expressed as a linear combination of 3 and 7 so 1 is 7 plus 3 into minus 2 therefore minus 2 is a solution for $3x$ congruent to $1 \pmod{7}$, this 7 can be ignored since we are taking mod 7 on both sides, so we have 3 into minus 2 equals $1 \pmod{7}$ so minus 2 is a solution for this but, minus 2 is the same as $5 \pmod{7}$.

(Refer Slide Time: 40:00)

5 is the unique soln
of $3x \equiv 1 \pmod{7}$
in $[0, 6]$

 $3x \equiv 5 \pmod{7}$ ✓
25 is a soln
 $25 \equiv 4 \pmod{7}$
← 4 solutions for

Therefore, 5 is the unique solution of $3x \equiv 1 \pmod{7}$ in 0 to 6 in the interval 0 to 6, 5 is a unique solution for this congruence. But, what we need is a solution not for this congruence but, for $3x$ is congruent to $5 \pmod{7}$ this is what we want to solve since, 5 is a solution for $3x$ is congruent to $1 \pmod{7}$, 5 into 5 25, is a solution for $3x \equiv 5 \pmod{7}$ but 25 is $4 \pmod{7}$, 21 plus

4 therefore 4 is a solution for this congruence $3x \equiv 5 \pmod{7}$, of course substituting 4 here you can readily verify $3 \times 4 = 12$ which is $5 \pmod{7}$ so it is indeed a solution.

(Refer Slide Time: 41:16)

The image shows handwritten mathematical work on a blackboard. It starts with the congruence $3x \equiv 5 \pmod{7}$. Below this, it shows $15x \equiv 25 \pmod{35}$, where the modulus 35 is underlined. The next line is the interval $[0, \dots, 34]$. Then, the general form of the solution is given as $4 + t \cdot 7$ where $t \in \mathbb{Z}$. Finally, the solutions within the interval are listed as 4, 11, 18, 25, 32 in $[0, 34]$, with the interval notation also underlined.

So we have found a solution for $3x \equiv 5 \pmod{7}$ but we want the solution for $15x \equiv 25 \pmod{35}$ since we want the solution mod 35 we would like solutions in the range 0 to 34 both inclusive we know that 4 is a solution, 4 is the unique solution for $3x \equiv 5 \pmod{7}$ but, then 4 plus t into 7 where t belongs to \mathbb{Z} the set of integers, is also a solution. So any integer of the form 4 plus $7t$ is a solution so 4 is a solution 4 plus 7, 11 is a solution 11 plus 7 18 is a solution, 25 is also solution, 32 is a solution, but these are the solutions in 0 to 34 so these are all solutions for $15x \equiv 25 \pmod{35}$ so this we find all solutions within the interval 0 to 34 that is it from the lecture, hope to see you in the next, Thank you.
