Lecture 35:
Chinese Remainder Theorem

Welcome to the NPTEL mock on discrete mathematics this is the sixth lecture on the number theory,

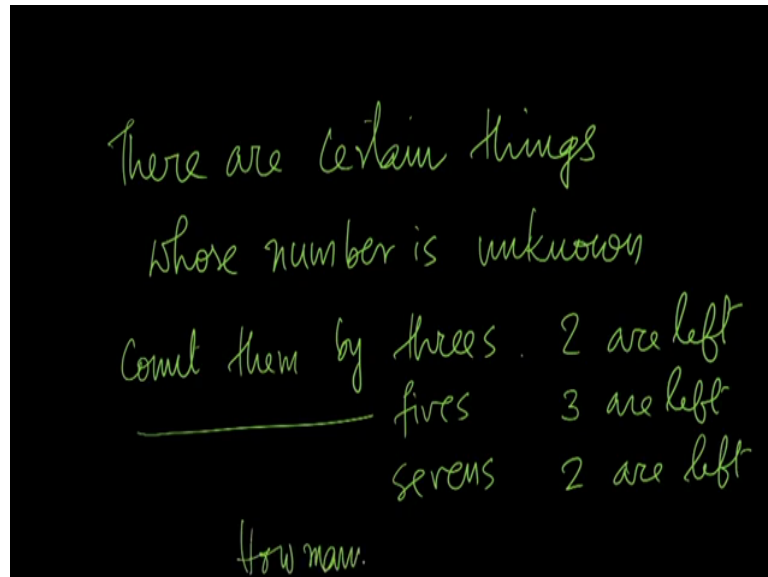

(Refer Slide Time: 00:40)

Today we study the Chinese remainder theorem, Chinese remainder theorem is one of the oldest mathematical theorem, it has been known since ancient times the first record of this problem was found in Chinese (())(0:57) on mathematics called Sunzi dated to 3rd to 5th century of the

Common Era but a statement of the problem could be found at but the first known algorithmic solution was due to Indian mathematician Aryabhata who lived in the 6th century of the Common Era. The India mathematician Brahmagupta who lived almost the century later this is also known to have a been aware of the problem as well as the solution.

(Refer Slide Time: 1:49)

There are certain things
whose number is unknown
Count them by threes . 2 are left
fives 3 are left
sevens 2 are left
How many.

The Chinese (())(1:48) in which the problem first appears states thus, there are certain things whose number is unknown that is there is an unknown variable, count them by the threes 2 are left count then by fives 3 are left count then by sevens 2 are left how many are there, in other words.

(Refer Slide Time: 02:50)

$$\left. \begin{array}{l} x \bmod 3 \equiv 2 \\ x \bmod 5 \equiv 3 \\ x \bmod 7 \equiv 2 \end{array} \right\} \begin{array}{l} \text{Congruences} \\ \text{Simultaneously} \end{array}$$
$$x = ?$$

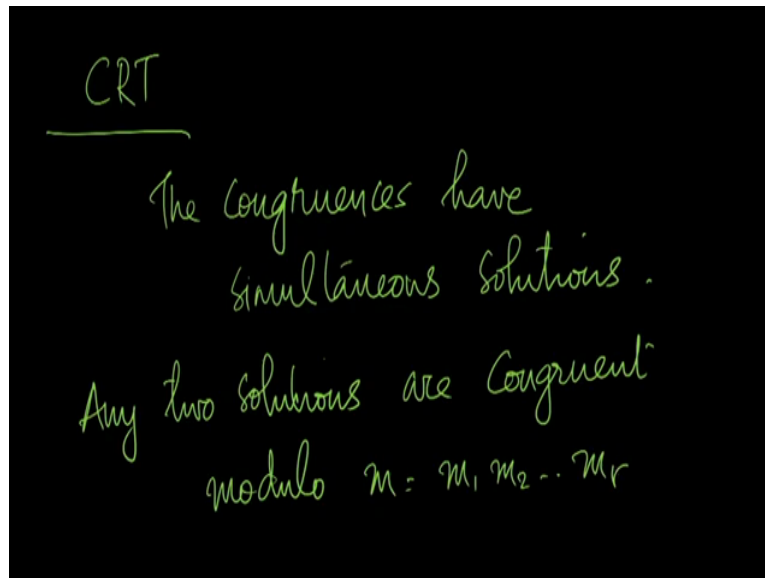

Let us see we have an unknown integer x what we want is that $x \bmod 3$ is 2 $x \bmod 5$ is 3 $x \bmod 7$ is 2. What is x , this is the question that the Chinese mathematician posed basically we have to solve these three congruences simultaneously, that is we need a simultaneous solution of a set of congruences.

(Refer Slide Time: 03:41)

Let m_1, \dots, m_r be +ve integers
that are pairwise coprime.
 a_1, \dots, a_r are integers
 $1 \leq i \leq r, x \equiv a_i \pmod{m_i}$

So now let us look at the general statement of the problem. So let us see m_1 through m_r are let these be positive integers that are pairwise coprime let us say even though a_i are integers we have a set of congruences a congruence is to be precise the i th congruence says that x is congruent to $a_i \bmod m_i$.

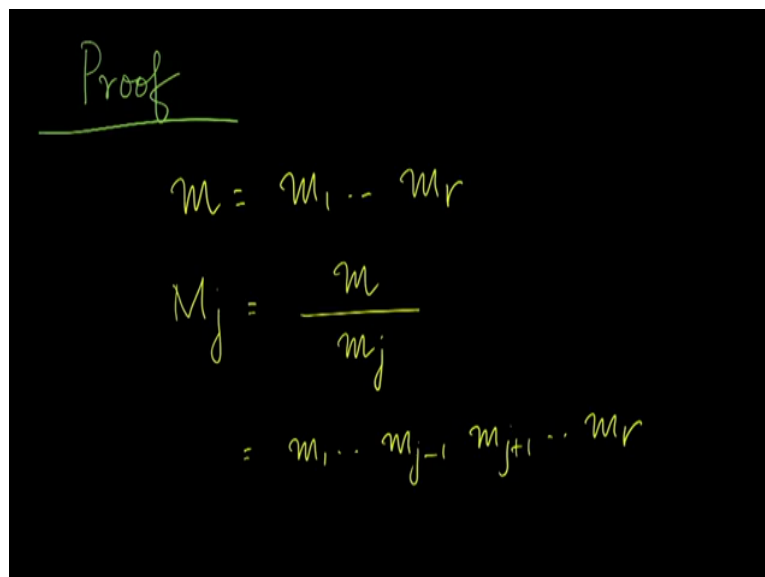

(Refer Slide Time: 04:47)

Then the Chinese remainder theorem says that in this context the congruences have simultaneous solution in particular any two such solutions are congruent to modulo m where m is the product of m_1 through m_r .

So that is what Chinese remainder theorem says, in this context where we have a set of positive integers r positive integers to be precise which are pair wise coprime which means the GCD of any pair is 1, then also given r , a 1 through a_r that are r integers and we have these congruences r congruences x is congruent to $a_i \pmod{m_i}$ in this context what the theorem says is that, this congruence is do have simultaneous solutions and any two solutions are congruent modulo m where m is the product of m_1 through m_r .

(Refer Slide Time: 06:03)

So let us see proof of this so small m is the product of m_1 through m_r let us define capital M_j as small m divided by small m_j which means capital M_j is m_1 through m_j minus 1 and then m_j plus 1 through m_r that is we take a product of all the m 's except m_j .

(Refer Slide Time: 06:44)

$$\begin{aligned} & \text{GCD}(M_j, m_j) \\ &= \text{GCD}(m_1 \dots m_{j-1} m_{j+1} \dots m_r, m_j) \\ &= 1 \\ & M_j \text{ and } m_j \text{ are co-prime} \end{aligned}$$

Then what would be the GCD of M_j and small m_j that is we are seeking the GCD of this product m_1 through m_j minus 1 m_j plus 1 through m_r and m_j . Now what we know is that the m_j 's are all pair wise coprime so m_j is coprime with m_1 m_2 etc. each of these m 's which means m_j is coprime with the argument on the left hand side which means we have a 1 as the GCD of these, in other words m_j and capital M_j and small m_j are coprime. Product relatively prime. coprime is another word for it.

(Refer Slide Time: 07:46)

$$\begin{aligned} & M_j x \equiv 1 \pmod{m_j} \\ & M_j \text{ and } m_j \text{ are co-prime} \\ & \text{This congruence has a unique solution} \\ & \text{in } [0, \dots, m_j - 1] \end{aligned}$$

Let us consider this congruence now capital M_j x is $1 \pmod{m_j}$ so here we know that M_j and m_j are coprime that is what we have just shown, therefore by the discussion that we had in the previous classes we know that this congruence has a unique solution in 0 to m_j minus 1 so there is a b_j within this range which is a solution for this.

(Refer Slide Time: 08:40)

Consider that solution
 $\rightarrow M_j^{-1}$
 $M_j \cdot M_j^{-1} = 1 \pmod{m_j}$

So consider that solution, that unique solution in the range 0 to m_j minus 1 . Let us denote it by M_j inverse what we find is that M_j multiplied by M_j inverse is $1 \pmod{m_j}$ so that is why we called it the inverse M_j multiplied by M_j inverse is $1 \pmod{m_j}$.

(Refer Slide Time: 09:15)

$M_j \cdot M_j^{-1} = (m_1 \dots m_{j-1} m_{j+1} \dots m_r) M_j^{-1}$
 $M_j \cdot M_j^{-1} \equiv 0 \pmod{m_i}, i \neq j$

But, then M_j multiplied by M_j inverse can be written as m_1 through m_j minus 1 small m_j plus 1 through m_r multiplied by M_j inverse. Therefore, $M_j M_j$ inverse is $0 \pmod{m_i}$ when i is

not equal to j because m_i will feature here when i not equal to j therefore m_i will divide this factor therefore it would divide the entire product therefore $M_j M_j^{-1}$ is divisible by m_i when i is not equal to j .

(Refer Slide Time: 10:22)

$$\begin{aligned}
 x_0 &= \sum_{j=1}^r M_j M_j^{-1} a_j \\
 x_0 &= M_1 M_1^{-1} a_1 + \underbrace{(M_2 M_2^{-1} a_2 + \dots + M_r M_r^{-1} a_r)}_{\text{mod } m_1} \\
 &\equiv M_1 M_1^{-1} a_1 \pmod{m_1} \\
 &\equiv a_1 \pmod{m_1}
 \end{aligned}$$

So this naturally suggest that, we should x naught which is of this form take the sum of j varying from 1 to r of $M_j M_j^{-1} a_j$ so this is what x naught is. Now x naught can be written as $M_1 M_1^{-1} a_1$ plus $M_2 M_2^{-1} a_2$ through $M_r M_r^{-1} a_r$ this we find is congruent to $M_1 M_1^{-1} a_1 \pmod{m_1}$. That is because M_2 is a multiple of small m_1 , m_3 so multiple small m_1 and so on, similarly M_r is also multiple of small m_1 , therefore this entire quantity within the brackets will go to 0, but then M_1 multiplied by M_1^{-1} we know is 1 mod M_1 therefore this is congruent to $a_1 \pmod{m_1}$. In other words, x naught is congruent to $a_1 \pmod{m_1}$.

(Refer Slide Time: 11:53)

$$\begin{aligned}x_0 &= M_2 M_2^{-1} a_2 + (M_1 M_1^{-1} a_1 + M_3 M_3^{-1} a_3 + \dots + M_r M_r^{-1} a_r) \\ &\equiv a_2 \pmod{m_2} \\ \forall i, 1 \leq i \leq r, \quad x_0 &\equiv a_i \pmod{m_i} \\ \hline x_0 &\text{ is a simultaneous soln.} \checkmark\end{aligned}$$

x_0 can also be written as $M_2 M_2^{-1} a_2$ plus $M_1 M_1^{-1} a_1$ plus $M_3 M_3^{-1} a_3$ plus all the way to $M_r M_r^{-1} a_r$ that is the remaining terms if I take the congruence of this modulo m_2 . We find that the quantity within the bracket again goes to 0, because small m_2 divides M_1 M_3 etc. Therefore, the quantity within the bracket is 0, and $M_2 M_2^{-1}$ is 1 mod m_2 therefore this is $a_2 \pmod{m_2}$. So continuing like this we find that for every i with $1 \leq i \leq r$, x_0 is congruent to $a_i \pmod{m_i}$ that proves one part of the theorem, so x_0 is indeed a simultaneous solution.

So looking back at the theorem we know that the theorem says the congruences do have simultaneous solutions so we have found one simultaneous solution, and then the rest of the theorem says that any two solutions are congruent modulo m where small m is m_1 through m_r so let us prove that now.

(Refer Slide Time: 13:45)

$$\begin{aligned} &\text{If } x_0 \text{ and } x_1 \text{ are both} \\ &\text{simultaneous solutions} \\ &\forall i, 1 \leq i \leq r, \\ &x_0 = a_i \pmod{m_i} \quad x_1 = a_i \pmod{m_i} \\ &(x_1 - x_0) = 0 \pmod{m_i} \end{aligned}$$

If x_0 and x_1 are both solutions both simultaneous solutions of the system then for every i 1 less than or equal to i less than or equal to r , we know that x_0 is $a_i \pmod{m_i}$ and x_1 is $a_i \pmod{m_i}$ which means $x_1 - x_0$ is $0 \pmod{m_i}$.

(Refer Slide Time: 14:36)

$$\begin{aligned} &m_i \mid (x_0 - x_1) \quad \forall i, 1 \leq i \leq r \\ &\text{LCM}(m_1, \dots, m_r) \mid (x_0 - x_1) \\ &\text{LCM}(m_1, \dots, m_r) = m = m_1 \cdot m_2 \cdot \dots \cdot m_r \\ &m \mid (x_0 - x_1) \Rightarrow x_1 \equiv x_0 \pmod{m} \end{aligned}$$

In other words m_i divides $x_0 - x_1$, for every i since every m_i divides $x_0 - x_1$, then the least common multiple of m_1 through m_r must also divide $x_0 - x_1$, but then what is the LCM of m_1 through m_r this is nothing but m which is the product of m_1 through m_r that is because m_i and m_j are coprime with each other for any i not equal to j . So the LCM of these is nothing but m so what we have is that m divides $x_0 - x_1$, in other words x_1 is congruent to $x_0 \pmod{m}$ that is precisely what the theorem says. If

for any two solutions these two solutions are congruent to each other modulo m . So that completes the proof of the theorem.

(Refer Slide Time: 15:50)

Example $r=4$

$$\begin{aligned} x &\equiv a_1 \pmod{11} && \text{--- } 11^1 \\ x &\equiv a_2 \pmod{16} && \text{--- } 2^4 \\ x &\equiv a_3 \pmod{21} && \text{--- } 3^1 \times 7^1 \\ x &\equiv a_4 \pmod{25} && \text{--- } 5^2 \end{aligned}$$

$11, 16, 21, 25$ pairwise coprime
 m_1, m_2, m_3, m_4

So now, let us work out an example let us say we have a congruence of this form x is congruent to $a_1 \pmod{11}$ x is also congruent to $a_2 \pmod{16}$ x is congruent to $a_3 \pmod{21}$, x is congruent to $a_4 \pmod{25}$. So 11 is a prime 16 is 2 power 4, 21 is 3 into 7 so 3 power 1 into 7 power 1, 25 is 5 power 2. So, there are all relatively prime. That is 11, 16, 21, 25 are all pairwise coprime so these are respectively m_1, m_2, m_3 and m_4 of the theorem. Here r is 4 so we have considering a problem of size 4.

(Refer Slide Time: 17:12)

$$\begin{aligned} m &= 11 \times 16 \times 21 \times 25 \\ &= \underline{92400} \\ M_1 &= \frac{m}{m_1} = \frac{92400}{11} = 8400 \\ M_2 &= \frac{m}{m_2} = \frac{92400}{16} = 5775 \end{aligned}$$

Now, small m is defined as the product of this 11 into 16 into 21 into 25 which is 92400. Then capital M1 would be small m divided by small m1 which is 92400, divided by 11 which is 8400, M2 is small m divided by small m2 which is 5775.

(Refer Slide Time: 17:55)

Handwritten calculations on a blackboard:

$$M_3 = \frac{m}{m_3} = \frac{92400}{21} = 4400$$

$$M_4 = \frac{m}{m_4} = \frac{92400}{25} = 3696$$

Below the calculations, the variables are listed:

$$M_1, M_2, M_3, M_4$$

$$m_1, m_2, m_3, m_4$$

M3 is small m divided by 21 92400 divided by 21 this is small m3 which is 4400 and capital M4 is small m divided by small m4 which is 92400 divided by 25, which is 3696 so we have to now find the inverses of M1, M2, M3 and M4, modulo small m1, small m2, small m3 and small m4 respectively. So let us try to find those inverses.

(Refer Slide Time: 18:47)

Handwritten modular arithmetic on a blackboard:

$$M_1 x \equiv 1 \pmod{m_1}$$

$$8400 x \equiv 1 \pmod{11}$$

$$8400 \equiv 7 \pmod{11} \quad \begin{matrix} 8393 \\ 17-6=11 \end{matrix}$$

$$7x \equiv 1 \pmod{11}$$

First we have to solve this M1 of x is 1 mod small m1 that we have to find the inverse of capital M1 with respect to small m1 which is 8400 x is congruent to 1 mod 11 let us 8400 is 7

mod 11 8393, 8 plus 9 17 3 plus 3 6 so 17 minus 6 is 11 so this is divisible by 11 so 8400 is 7 mod 11. So this congruence can be written as $7x \equiv 1 \pmod{11}$ so we only need to find the inverse of 7 with respect to 11 that would also be the inverse of 8400 with respect to 11.

(Refer Slide Time: 19:44)

Handwritten mathematical derivation on a blackboard showing the steps to solve the congruence $7x \equiv 1 \pmod{11}$ using the Euclidean algorithm. The equations are:

$$7x \equiv 1 \pmod{11} \quad 11, 7$$

$$4 = 11 - 7$$

$$3 = 7 - 4$$

$$1 = 4 - 3 = 4 - (7 - 4)$$

$$= 2 \times 4 - 7$$

$$= 2(11 - 7) - 7$$

$$= 2 \times 11 - 3 \times 7$$

On the right side of the blackboard, the following congruences are written:

$$1 \equiv -3 \times 7 \pmod{11}$$

$$\underline{-3 \equiv 8 \pmod{11}}$$

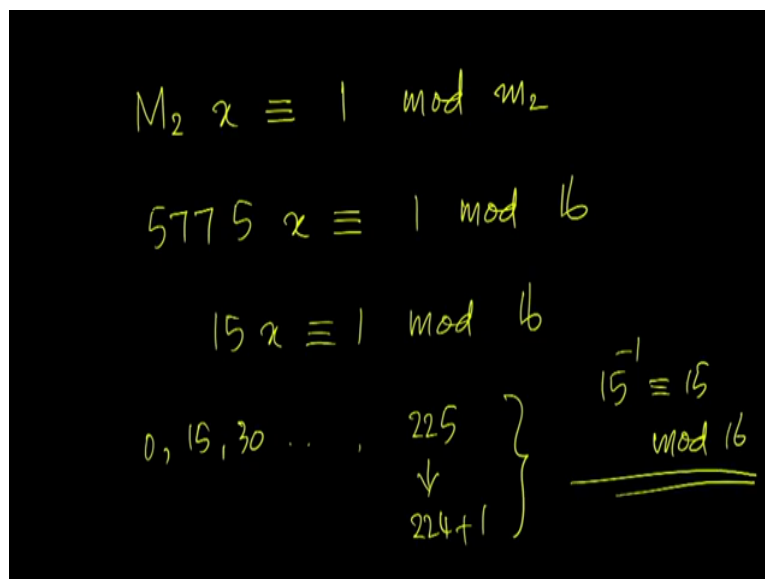

So this is what we have to solve, $7x \equiv 1 \pmod{11}$ of course you could use Euclid's algorithm for doing this if we use Euclid's algorithm on 11 and 7 we find that 4 is 11 minus 7 then 3 is 7 minus 4, 1 is 4 minus 3 which is then 4 minus 7 minus 4 which is 2 into 4 minus 7 but 4 is 11 minus 7 so into 11 minus 7 minus 7 so that will be 2 into 11 minus 3 into 7, so if you take modulo 11 on both sides of the equation we find that 1 is congruent to minus 3 into 7 so we want the solution for $7x \equiv 1 \pmod{11}$ so we find that minus 3 is a solution. But minus 3 is 8 mod 11 so 8 is a solution as well.

(Refer Slide Time: 21:06)

Of course an easier way of solving would be to count the multiples of 7 0, 7, 14, 21, 28, 35, 49, and 56. 56 is 1 mod 11. So 7 inverse mod 11 is 8.

(Refer Slide Time: 21:37)

Then we have to solve this congruence $M_2 x \equiv 1 \pmod{m_2}$ or in other words $5775 x \equiv 1 \pmod{16}$, 5760 is a multiple of 16 so we have a 5760 plus 15 x here so its 15 x is congruent to 1 mod 16 so when you run through the multiplication table for 15 you find that 0, 15, 30 etc. However, none of them 1 mod 16 until you comes to 225 the 255 is a 224 plus 1 224 is 14 into 16, so we find that 15 is the inverse of 15 mod 16. So the second solution is 15.

(Refer Slide Time: 22:38)

$$\begin{aligned}M_2 x &\equiv 1 \pmod{m_3} \\4400 x &\equiv 1 \pmod{21} \\11x &\equiv 1 \pmod{21} \\x &\equiv 2 \qquad 11^{-1} = 4400^{-1} \equiv 2 \pmod{21}\end{aligned}$$

And the 3rd one is a $M_3 x$ is congruent to 1 mod small m_3 , what is capital M_3 that is 4400 that is 1 mod 21 4400, 4200 and then 200 left 189 11, $11x$ is 1 mod 21 so as you can readily see 21 is 1 mod 21 so x equal to 2 is a solution which means 11 inverse which is also 4400 inverse is 2 mod 21 so there is a 3rd solution.

(Refer Slide Time: 23:34)

$$\begin{aligned}M_4 x &\equiv 1 \pmod{m_4} \\3696 x &\equiv 1 \pmod{25} \\21x &\equiv 1 \pmod{25} \\0 \quad 21 \quad 42 \quad \dots \quad \underline{126} \quad x &\equiv \underline{6} \pmod{25}\end{aligned}$$

And then coming to the 4th one $M_4 x$ is 1 mod small m_4 , which is 3696 x is 1 mod 25, 3696 is minus 4 3700 minus 4 which is 21. $21x$ is 1 mod 25 this is what we have to solve, so running through the multiples of 21 etc. When we come to 126 we find that it is 1 mod 25. So x equal to 6 is the solution the 4th solution.

(Refer Slide Time: 24:30)

$$\begin{aligned}M_1^{-1} &= 8 \\M_2^{-1} &= 15 \\M_3^{-1} &= 2 \\M_4^{-1} &= 6 \\M_1 M_1^{-1} a_1 + M_2 M_2^{-1} a_2 + M_3 M_3^{-1} a_3 + M_4 M_4^{-1} a_4 \\(8400 \times 8 a_1 + 5775 \times 15 a_2 + 4400 \times 2 a_3 + 3696 \times 6 a_4) \\&\text{mod } 92400\end{aligned}$$

So we have now the 4 solutions M1 inverse is 8 M2 inverse is 15, M3 inverse is 2, M4 inverse is 6 so a solution then would be M1 M1 inverse a1 plus M2 M2 inverse a2 plus M3 M3 inverse a3, plus M4 M4 inverse a4 which means 8400 into 8 a1 plus 5775 into 15 into a2, plus 4400 into 2 into a3, plus 3696 into 6 into a4.

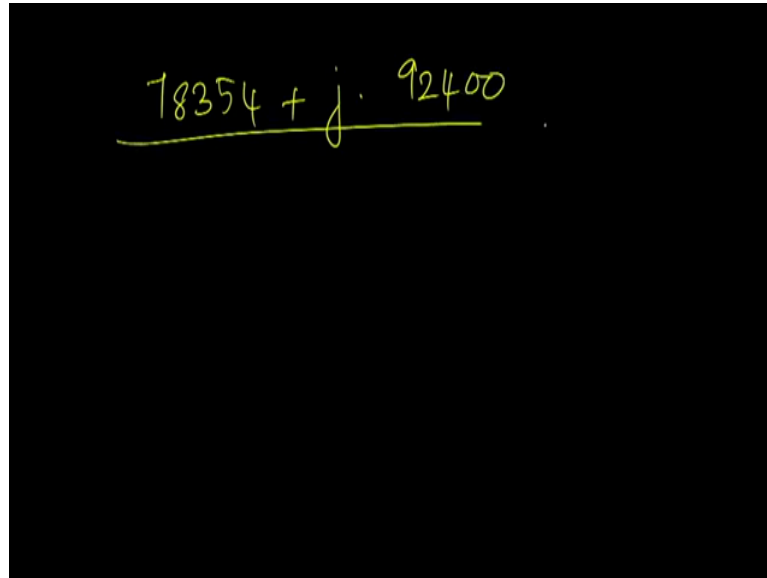

The whole of this modulo 92400 is the solution that we want. I have deliberately avoided choosing a1, a2, a3, a4 to show that the computation remains the same irrespective of these values so whatever a1, a2, a3, a4 are the solution will take on this from now we only have to plugin a1, a2, a3, a4.

(Refer Slide Time: 26:11)

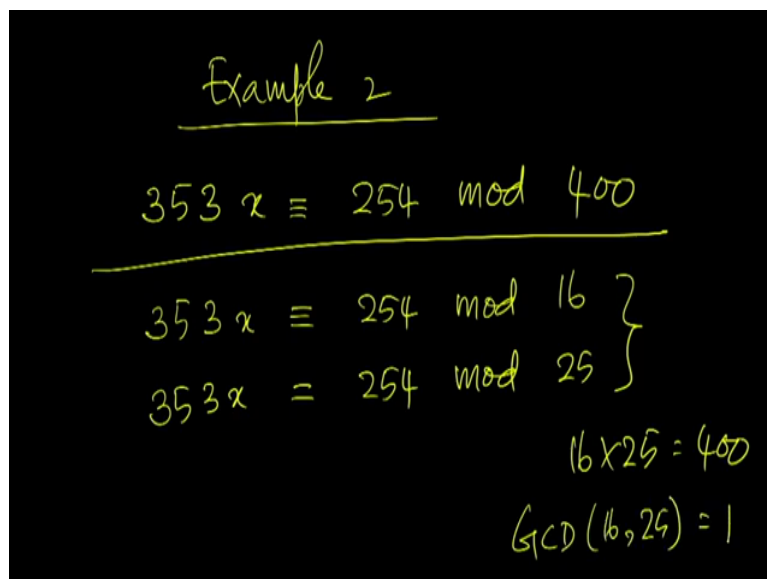

$$\begin{aligned}a_1 &= 1 & a_2 &= 2 & a_3 &= 3 & a_4 &= 4 \\x_0 &= 78354 \\78354 \text{ mod } 11 &= 1 \\78354 \text{ mod } 16 &= 2 \\78354 \text{ mod } 21 &= 3 \\78354 \text{ mod } 25 &= 4\end{aligned}$$

So let us assume that a_1 equals to 1, a_2 equal to 2, a_3 equal to 3, a_4 equal to 4 if this is the case plugin in these values we find that the solution x naught is 78354, verifying we find that $78354 \bmod 11$ is 1, $78354 \bmod 16$ is 2, $78354 \bmod 21$ is 3, $\bmod 25$ is 4. So this is $(())(27:08)$ solution that we seek.

(Refer Slide Time: 27:12)

A handwritten equation on a black background: $78354 + j \cdot 92400$. The entire expression is underlined.

Handwritten text on a black background:

Example 2

$$353x \equiv 254 \pmod{400}$$

$$\left. \begin{aligned} 353x &\equiv 254 \pmod{16} \\ 353x &\equiv 254 \pmod{25} \end{aligned} \right\}$$

$16 \times 25 = 400$
 $\text{GCD}(16, 25) = 1$

And then 78354 plus j into 92400 is the general solutions. So let us consider another example now so this is a familiar problem let a see we want to solve $353x$ is congruent to 254 modulo 400 we have seen two ways of solving this before so this is a 3rd way we could convert this into simultaneous congruences in this manner, $353x$ is congruent to 254 mod 16 and 254 mod 25 separately this is because 16 into 25 is 400 and 16 and 25 are relatively prime to each other.

(Refer Slide Time: 28:27)

$$\begin{aligned} 352 &= 320 + 32 \\ 353x &\equiv x \equiv 254 \equiv 14 \pmod{16} \\ \hline x &\equiv 14 \pmod{16} \end{aligned}$$

But then 352 is 320 plus 32 so that is a multiple of 16 so $353x$ is congruent to $x \pmod{16}$, which is equal to $254 \pmod{16}$ but then 254 is 240 plus 14 so 240 is a multiple of 16 so we have $14 \pmod{16}$. So the first congruence namely $353x$ is congruent to $254 \pmod{16}$ reduces to x congruent to $14 \pmod{16}$ so this is one congruence that we have.

(Refer Slide Time: 29:17)

$$\begin{aligned} 353x &\equiv 254 \pmod{25} \\ 3x &\equiv 4 \pmod{25} \\ x &\equiv a_i \pmod{m_i} \end{aligned}$$

The other congruence namely $353x$ is congruent to $254 \pmod{25}$ can be simplified like this $353x$ is $3x \pmod{25}$, 350 plus 3 and 254 is 250 plus 4 so there is 4, $\pmod{25}$, so this congruence simplifies to $3x$ congruent to $4 \pmod{25}$, but this is not in the desired form because we would like this to be in this form. But, here we have $3x$ on the left hand side.

(Refer Slide Time: 30:01)

$$\begin{aligned} 3x &\equiv 1 \pmod{25} \\ 3 \nmid 26 & \quad 3 \mid 51 \\ 3 \times 17 &\equiv 1 \pmod{25} \\ \hline 3x &\equiv 4 \pmod{25} \\ 17 \times 4 = 68 & \text{ is a soln for } 3x \equiv 4 \pmod{25} \end{aligned}$$

So let us solve $3x \equiv 1 \pmod{25}$ first so, considering the multiples of 25 plus 1 example consider 26 3 does not divide 26 but, 3 divides 51 which is 2 into 25 plus 1. Which means 3 into 17 is 1 mod 25 so 17 is a solution for this. so we have now a solution for $3x \equiv 1 \pmod{25}$ but, we are looking at the congruence $3x \equiv 4 \pmod{25}$ so if 17 is a solution for $3x \equiv 1 \pmod{25}$ then 17 into 4 which is 68 is a solution for $3x \equiv 4 \pmod{25}$.

(Refer Slide Time: 31:07)

$$\begin{aligned} x &\equiv 68 \pmod{25} \\ x &\equiv 18 \pmod{25} \\ \hline x &\equiv a_2 \pmod{m_2} \end{aligned}$$

In other words, $x \equiv 68 \pmod{25}$ is a solution or $x \equiv 18 \pmod{25}$ is a solution now this is in the desired form, this is in the $x \equiv a_2 \pmod{m_2}$ form so this is our second congruence.

(Refer Slide Time: 31:34)

$$\begin{aligned}x &\equiv 14 \pmod{16} \\x &\equiv 18 \pmod{25} \\m_1 &= 16 \quad m_2 = 25 \quad m = 400 \\M_1 &= \frac{400}{16} = 25 \quad M_2 = \frac{400}{25} = 16 \\a_1 &= 14 \quad a_2 = 18\end{aligned}$$

So now putting the two congruents together we have x congruent to 14 mod 16 x congruent to 18 mod 25, so now we can apply the Chinese remainder theorem here m_1 is 16, m_2 is 25 so small m is 400 capital M_1 is 400 by 16 which is 25 capital M_2 is 400 by 25 which is 16, a_1 is 14, a_2 is 18.

(Refer Slide Time: 32:19)

$$\begin{aligned}M_1 \quad x &\equiv 1 \pmod{m_1} \\25 \quad x &\equiv 1 \pmod{16} \\25 \times 9 &= 225 \equiv 1 \pmod{16} \\ \hline q &= 25^{-1} \pmod{16}\end{aligned}$$

So now we have to solve $M_1 x \equiv 1 \pmod{\text{small } m_1}$ which means we have to find the inverse of capital M_1 with respect to small m_1 or $25 x \equiv 1 \pmod{16}$ so taking the multiples of 25 we find that 225 is 1 mod 16 but, 225 is 25 into 9, so 9 is a solution so 9 is 25 inverse mod 16.

(Refer Slide Time: 32:55)

$$\begin{aligned}M_2 x &\equiv 1 \pmod{m_2} \\16x &\equiv 1 \pmod{25} \\16 \times 11 &= 176 \equiv 175 + 1 \equiv 1 \pmod{25} \\11 &= 16^{-1} \pmod{25}\end{aligned}$$

The other congruence we have to solve is $M_2 x \equiv 1 \pmod{m_2}$, which is $16x \equiv 1 \pmod{25}$ counting through the multiples of 16 we find that 16 into 11 this 176 which is 175 plus 1 so, $1 \pmod{25}$. Which means 11 is 16 inverse mod 25 so we now have the inverse is.

(Refer Slide Time: 33:37)

$$\begin{aligned}&(M_1 M_2^{-1} a_1 + M_2 M_1^{-1} a_2) \pmod{m} \\&(25 \times 9 \times 14 + 16 \times 11 \times 18) \pmod{400} \\&6318 \pmod{400} \\&= \underline{\underline{318 \pmod{400}}} \quad [0, \dots, 399]\end{aligned}$$

The first solution would be $M_1 M_2^{-1} a_1$, plus $M_2 M_1^{-1} a_2$, mod m which means 25 into 9 into 14, plus 16 into 11 into 18 mod 400 this looks out to 6318 mod 400 which is 318 mod 400. So this is the only solution in the range 0 to 399. So that is about the Chinese remainder theorem that is it from this lecture hope to see you in the next, Thank You.
