**Lecture 42**

In this lecture we will learn about 2 new algebraic structures namely rings and fields. We had learned about the groups, one way in which rings and fields are different from groups is, while we were talking about the groups there was only one operation but when we talk about rings and fields there are two operations and we will call these operations as addition and multiplication operations. So let us formally understand what is a ring.

(Refer Slide Time: 1:01)

Rings & Fields

Ring

A set  $R$  equipped with two operations  $+$ ,  $\times$  s.t.

- (i)  $(R, +)$  should be an Abelian group
- (ii)  $\times$  should be associative & should have an identity

$$a(b \cdot c) = (a \cdot b) \cdot c$$
$$a \cdot 1 = 1 \cdot a = a$$

(iii) Distributive laws

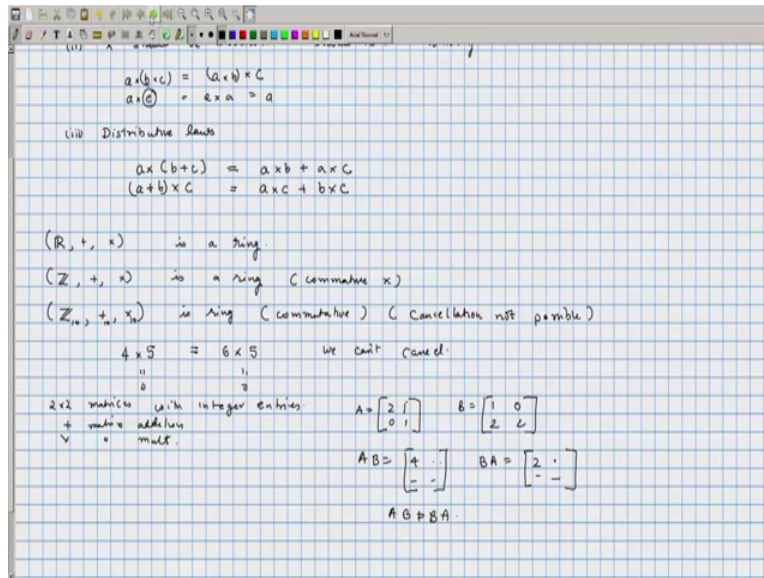

$$a \times (b + c) = a \times b + a \times c$$
$$(a + b) \times c = a \times c + b \times c$$

$(R, +, \times)$  is a ring.

$(\mathbb{Z}, +, \times)$  is a ring (commutative  $\times$ )

$(\mathbb{Z}_n, +, \times_n)$

$4 \times 5$	$=$	$6 \times 5$	we can't cancel.
11		11	
0		0	

So there is a set, so ring as a set  $R$ , equipped with 2 operations, let us call it as the addition and the multiplication operations. And these operations have to satisfy some properties. The first property is, if you just consider the set, with the addition operation, this should be an abelian group and if you look at the operation of multiplication then that should be associative and there should be a multiplicative identity.

So that should mean if you have elements  $a$ ,  $b$  and  $c$ ,  $a$  times  $b$  into  $c$  should be equal to  $a$  into  $b$  into  $c$  and there should exist an element  $e$  which can act as the multiplicative identity. So  $a$  times  $e$  should be equal to  $e$  times  $a$  should be equal to  $a$ . There should exist an element of this kind, okay.

The third property is how these, these operations interact with each other? So that is the distributive laws, namely if you multiply  $a$  with  $b$  plus  $c$  the product should be equal to  $a$  times  $b$  plus  $a$  times  $c$  for every  $a$ ,  $b$  and  $c$ . And if you have  $a$  plus  $b$  into  $c$ , so no matter whether you multiply on left or whether you multiply on right, the distributive law holds. So this will be equal to  $a$  into  $c$  plus  $b$  into  $c$ . So if you have a set equipped with 2 operations which behaves in this manner, then that is called as a ring.

Let us look at some key differences or key some non-requirements, this multiplication need not be an invertible operation, when we are look into addition for every element of the group, there is an element which can act as the additive inverse, the multiplicative inverses need not be present. Not just that even cancellation laws need in hold, okay we will see examples of all those.

So that is the way in which this is the general ring is different from let us say if you consider the ring of real numbers.

So the ring of real numbers, is many additional properties that, that we do not insist for a general ring. So let us see some examples, if you just take the set of real numbers with usual addition and the usual multiplication then clearly under addition real numbers form an abelian group and the multiplication has the distributive properties and that is associative and one can serve as the identity, so this is the ring.

Now let us look at the set of integers under the usual addition and multiplication, this is also a ring. But here you can see that there is mean under multiplication inverses is not defined. For example, if you take the element 9, there is no multiplicative inverse there is no element which you can multiply with 9 to get a 1. But this is a commutative ring, in the sense the multiplication operation is commutative.

Okay same applies for  $\mathbb{R}$  but  $\mathbb{Z}$  is a commutative ring but it is the non-zero element, if you look at it, not all of them are invertible, only invertible elements in this ring are the plus 1 and the minus 1. Let us look at another ring, if you look at the set of numbers, modulo 10, so the operations are mod 10 operations. So now the (multipli) the addition is mod 10 (multiplication) addition and the multiplication is mod 10 multiplication.

Now if you look at this ring, clearly this is a I mean you can verify that it will be a ring because addition is associative and the multiplication, there is a multiplicative identity and the multiplication is associative and the distributive laws holds. But now you can see that even cancellation laws does not really work. For example, if you have let us say 4 into 5, so that will be 20, that is equal to 0, is equal to let us say 6 into 5.

Both are 0 but we just cannot cancel off 5 and say that 4 equal 6 but this is again a commutative ring. But if you now take the set of matrices, if you look at matrices, so let say 2 cross 2 matrices where the entries are in are from the ring of integers and the addition is the usual addition and the multiplication is the matrix multiplication. Clearly this is not a commutative operation.

For example, if you take, say the matrix A is equal to  $\begin{pmatrix} 2 & 1 & 0 & 1 \end{pmatrix}$  and B is equal to  $\begin{pmatrix} 1 & 0 & 2 & 2 \end{pmatrix}$  okay, so AB if you compute the first element or the 1-1 element will be 2 into 1, 1 into 2, it will be 4 and the other elements would be something, whereas if you compute BA that is going to be 1 into 2

and 0 into 0, so this is going to start with 2. So clearly  $AB$  is not equal to  $BA$ . So matrix multiplication is not commutative and therefore  $V$  is matrices 2 cross 2 matrices with integers entries if you take those matrices they do form a ring but it does not have many other properties that we would have in other rings like it is not commutative and there is no cancellation may or may not be possible and okay so this is an example of a non-commutative ring.

(Refer Slide Time: 9:20)

Units of the Ring

Invertible elements of  $R$ .

$x$  is invertible if  $\exists y$  st  $xy = yx = 1$

Suppose  $y'$  is also an inverse,

$$(y'xy = y'1 = y')$$
$$\frac{1}{y}$$
$$\frac{1}{y}$$
$$y$$

But the invertible elements of  $R$  form a group under multiplication

$Z_{10}$ : Units are  $\{1, 3, 7, 9\}$

$$1^{-1} = 1$$
$$3^{-1} = 7$$
$$7^{-1} = 3$$
$$9^{-1} = 9$$

$x$  is invertible if  $\exists y$  st  $xy = yx = 1$

Suppose  $y'$  is also an inverse,

$$(y'xy = y'1 = y')$$
$$\frac{1}{y}$$
$$\frac{1}{y}$$
$$y$$

But the invertible elements of  $R$  form a group under multiplication

$Z_{10}$ : Units are  $\{1, 3, 7, 9\}$

$$1^{-1} = 1$$
$$3^{-1} = 7$$
$$7^{-1} = 3$$
$$9^{-1} = 9$$

Can 0 be a unit?

Now let us further explore the rings, so we will first define what are called as a units of the ring. Since we have a multiplication operation and we have multiplicative identity, we could consider all the elements that are invertible. So units are nothing but invertible elements of the ring. Okay for example, the first that we should ask is, if an element is invertible, is the inverse unique? Okay so what do we mean by invertible elements?

So  $x$  is invertible, if there exist  $y$  such that  $xy$  is equal to  $yx$  is equal to 1 where 1 is the identity, we know that in the rings there is an identity. Okay now if there is one such  $x$ , will it be unique? It will be unique because suppose there is a  $y$  prime, suppose there is a  $y$  prime with similar

properties, for an invertible element  $x$ , suppose there is a  $y$  prime. So if you consider  $xy$  equals 1 and multiply both side of this equation with  $y$  prime, okay so  $y$  prime into 1 this is equal to  $y$  prime and we can use associativity here and say that  $y$  prime times  $x$  that is going to be identity because  $y$  prime was an inverse.

So this will be 1 into  $y$  and that is going to be equal to  $y$  because 1 is the identity, identity multiplied by any element you see 1. So this would imply that  $y$  is equal to  $y$  prime, so if an element is invertible, its inverse is unique. Now let us collect all the invertible elements together okay that is, they are going to be called as units and you can verify this, the invertible elements of  $R$  forms a group under multiplication.

We have already seen this when we were looking at certain groups, if we were looking at  $Z_{10}$ , that is a ring and invertible elements are namely 1, 3, 7 and 9. These were the numbers which are relatively prime to 10 and if take those elements, those alone are the invertible elements and you can check that the inverse of 1 is going to be itself, 3 inverse is 7 because 3 into 7 is 1 and 7 inverse is 3 and 9 inverse is 9 itself because 9 into 9 is 1.

Now we can define, what is a field? So we will rule out the trivial cases by saying that whenever we are thinking about rings or fields, the additive identity and the multiplicative identity they are going to be separate, they are going to be, they are going to be, they are 2 different distinct things. Okay so there will be at least 2 elements in all the rings that we are looking at. So can 0 be a unit? Can 0 be inverted?

Okay so you can verify that this cannot be the case and therefore in any ring the best that we can hope for is the non-zero elements are invertible and such a ring with the additional property that it that the multiplication is commutative is called as a field.

(Refer Slide Time: 13:18)

Field  $(F, +, \times)$

- (i)  $F \setminus \{0\}$  forms a group under  $\times$
- (ii)  $F$  is a ring
- (iii)  $\times$  is commutative

$(\mathbb{R}, +, \times)$  is a field.

$(\mathbb{Z}_p, +, \times)$  is a field iff  $p$  is prime.

Example:

Consider  $2 \times 2$  matrices with  $x, y$  are elements of a field.

$$\begin{bmatrix} x & y \\ -y & x \end{bmatrix}$$

$$\begin{bmatrix} x & y \\ -y & x \end{bmatrix} + \begin{bmatrix} x' & y' \\ -y' & x' \end{bmatrix} = \begin{bmatrix} (x+x') & (y+y') \\ -(y+y') & (x+x') \end{bmatrix}$$

- (ii)  $F$  is a ring
- (iii)  $\times$  is commutative

$(\mathbb{R}, +, \times)$  is a field.

$(\mathbb{Z}_p, +, \times)$  is a field iff  $p$  is prime.

Example:

Consider  $2 \times 2$  matrices with  $x, y$  are elements of a field.

$$\begin{bmatrix} x & y \\ -y & x \end{bmatrix}$$

$$\begin{bmatrix} x & y \\ -y & x \end{bmatrix} + \begin{bmatrix} x' & y' \\ -y' & x' \end{bmatrix} = \begin{bmatrix} (x+x') & (y+y') \\ -(y+y') & (x+x') \end{bmatrix}$$

$$\begin{bmatrix} x & y \\ -y & x \end{bmatrix} \begin{bmatrix} x' & y' \\ -y' & x' \end{bmatrix} = \begin{bmatrix} xx' - yy' & xy' + yx' \\ -yy' - xy' & xx' - yy' \end{bmatrix} = AB$$

$$\begin{bmatrix} x' & y' \\ -y' & x' \end{bmatrix} \begin{bmatrix} x & y \\ -y & x \end{bmatrix} = \begin{bmatrix} x'x - y'y & x'y + y'x \\ -y'x - x'y & x'x - y'y \end{bmatrix} = A'B$$

Okay so let us define what a field is, so again we will denote the set by  $F$  and there are 2 operations namely plus and multiplication. So this is a field if  $F$  minus this 0 element forms a group under multiplication and of course  $F$  has to be a ring for these operations and then the third requirement is multiplication is commutative.

Okay so if these conditions are satisfied then that is called as a field. So we will see some examples of field, if you look at the real numbers under the usual addition and multiplication, this is a field. Because if you take a non-zero elements, each of them is invertible and they form a group under multiplication and of course multiplication is commutative.

We will see far more interesting fields when we are looking at finite cases, if we look at let us say  $\mathbb{Z}_P$  under mod  $P$  addition and multiplication this is also a field if and only if  $P$  is prime. Okay now group is here we have checked that if you consider elements modulo, multiplication modulo  $P$ , the elements  $1$  to  $P$  minus  $1$  will form a group when  $P$  is a prime number and if it not a prime number, they will not form a group.

So this automatically means that we will have fields of size  $P$  for any prime. Can there be a field of size  $6$ ? Can there be a field of size  $9$  and so on? These are important questions and we will see the answers to some of these questions. So let us first look at some examples of fields, so let us look at matrices. Okay, so let us consider  $2$  cross  $2$  matrices which are skew symmetric, we have a very specific form for these, let us say they are of the form  $x$   $y$  and then minus  $y$   $x$ .

So look at  $2$  cross  $2$  matrices of this form, where  $x$  and  $y$  these are elements of a field, okay. Do these matrices, these collection of matrices form a field? Clearly they form a ring because if you have a matrix  $x$   $y$  minus  $y$   $x$  and if you add it to another matrix of that kind  $x'$   $y'$  minus  $y'$   $x'$ , what is get is another  $2$  cross  $2$  matrix which is of the same form.

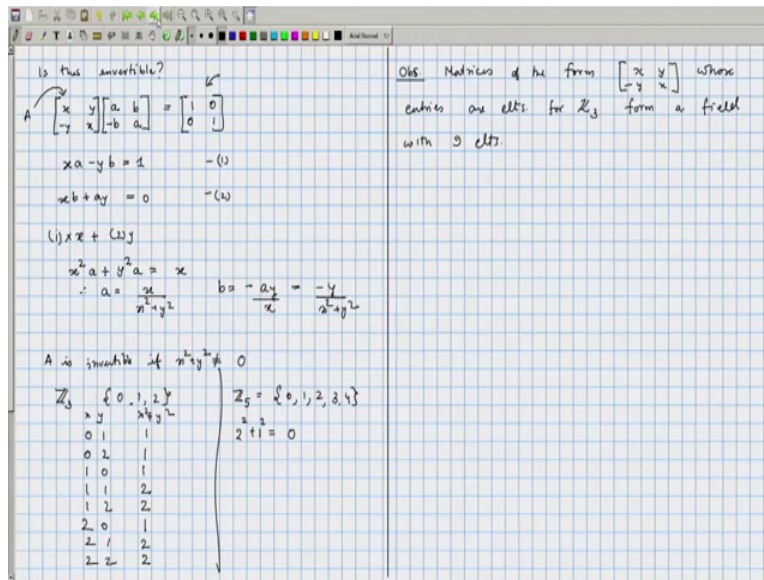

So  $x$  plus  $x'$  will appear on the diagonal and  $y$  plus  $y'$  and its negative will appear on the off diagonal. Okay so closure property is there and you can verify that under addition these do form a group. The multiplication is also well defined and you can see that the multiplication will in fact be commutative, if you just consider the matrices of this kind, okay so let just say its compute  $x$   $y$ , let us take this matrix and find its product with another such matrix.

So the diagonal entries are going to be  $x-x'$  plus  $y-y'$ , so the product is going to be minus  $y$   $x'$  minus  $x$   $y'$  which is the negative of the 1, 2 and 3. And the diagonal elements are going to be  $x-x'$  minus  $y-y'$ . Then you can see that the result is symmetric in  $x$  and  $x'$  or  $y$  and  $y'$  because if you just change, I mean if you compute them product of  $x$   $y'$  minus  $y'$   $x'$  with  $x$   $y$  minus  $y$   $x$ , that is going to be exactly same as, so if you call this as  $AB$ , this is also going to be equal to  $BA$ , okay.

So  $AB$  equal to  $BA$  and therefore these matrices when you multiply them out, they are I mean the multiplication is commutative.

(Refer Slide Time: 18:48)

But is invertible is the question. So that answer is going to depend on the particular field from which are choosing, okay so if you have a matrix  $x \ y$  minus  $y \ x$ , if it is invertible, let us first try and do the symbolic inversion of this matrix. So if you have another matrix which inverts then it should be other formed  $a, b$  minus  $b, a$  and this product should be equal to  $1, 0, 0, 1$  because this is going to be the multiplicative identity nothing else can act as the multiplicative identity.

So when will matrices be invertible? Okay so here the requirement is  $x \ a$ , the product would be  $x \ a$  minus  $y \ b$  that should be equal to  $1$ , that is one of the requirements and the other requirement will be that  $x \ b$  plus  $a \ y$  should be equal to  $0$ . We can solve these simultaneous equations for  $a$  and  $b$  and so if you call this as equation 1 and this is equation 2, we just multiply 1 into  $x$  plus 2 into  $y$ .

What we will get is  $x^2 a$  plus  $y^2 a$  is equal to  $x$  and therefore  $a$  is equal to  $x$  by  $x^2 + y^2$  and similarly you can show that  $b$  is equal to minus  $y$  by  $x^2 + y^2$  and that is going to be minus  $y$  by  $x^2 + y^2$  okay and therefore we can carry out this operation as long as  $x^2 + y^2$  is not equal to  $0$ . Okay so these are going to be invertible if, so the matrix  $A$ , if we consider this as a matrix  $A$ ,  $A$  is invertible if  $x^2 + y^2$  is not equal to  $0$  okay.

We had assumed that the elements come from a field, if they come from a field, all the non-zero entries will be invertible. So  $x^2 + y^2$  its inverse can be calculated, multiplied with

x you will get the value of a and similarly you can find the value of b. So if you look at our field and if  $x^2 + y^2$  is not equal to 0 for any choice of x and y, ofcourse when x and y are both 0  $x^2 + y^2$  will be equal to 0 but in that case the matrix we are talking about is the all 0 matrix. So all 0 matrix we did not mean that will not have to be inverted, so all that we have to check is, are all the non-zero matrices invertible? Okay and that is the case if  $x^2 + y^2$  is not equal to 0.

Now if you take  $Z_3$ , this is 3 elements namely 0, 1 and 2. Okay so x has 3 possibilities, y has 3 possibilities, out of it 0-0 possibility we could discount and the other 8 possibilities you we manually check, so let us say 0 1 0 2, 0 0 we had skipped. So these are the x y values and then 10, 11, 12, 20, 21, 22 and  $x^2 + y^2$ , all those things computed mod 3, this is 1, this is 1, 1, 2, 1 square plus 2 square is 5 mod 3 that is again 2, this is 1, 2 square is 4 plus 1 5 so this is 2, 8 mod 3 that is again 2.

Okay so none of these are equal to 0, so if you choose elements from  $Z_3$ , they are going to form a field. So what we have proved is the following matrices of the form  $x^2 + y^2$ , whose entries are elements of  $Z_3$  form a field and this field has exactly 9 elements because x has 3 choices and y has 3 choices, once x and y has been fixed the matrix gets fixed. So and this is a matrix with, this is a field with 9 elements because we have constructed a field with 9 elements. We will see other methods for constructing fields.

But now maybe a similar thing would work, if we take  $Z_5$ , we will get a field with 25 elements. If x and y, so let us try and choose Z from, x and y from  $Z_5$ . Okay so that has these elements 1, 2, 3, 0, 1, 2, 3, 4 but here if we take  $x^2 + y^2$ , if you take 2 and 1, so 2 square plus 1 square that is equal to 0. So if we take elements from  $Z_5$ , they do not form a field. Okay so we will probably have to explore other methods to come up with fields of size 25.

(Refer Slide Time: 25:00)

Polynomials

$$f(x) = a_0 + a_1x + \dots + a_nx^n$$

$a_n \neq 0$

$f(x)$  is a poly of degree  $n$   
 $\frac{d}{dx} x^d$  has non zero coeff.  
 largest

$f(x) \leftrightarrow (a_0, \dots, a_n)$

A Polynomial is a finite sequence of elements from a ring.

Sum:

$(a_0, \dots, a_n)$	$a(x) = x^2 + 2x + 5$
$(b_0, \dots, b_n)$	$b(x) = x^3 + 7x + 9$
if $m \neq n$ $m > n$	$a(x) + b(x) = x^3 + x^2 + 10x + 14$
Prod of the sequences with $o_p$	$a(x) \cdot b(x) = x^5 + 2x^4 + 5x^3 + 9x^2 + 16x^2 + 18x + 45$
$c_i = a_i \cdot b_i$	

A Polynomial is a finite sequence of elements from a ring.

Sum:

$(a_0, \dots, a_n)$	$a(x) = x^2 + 2x + 5$	$\mathbb{Z}_{10}$
$(b_0, \dots, b_n)$	$b(x) = x^3 + 7x + 9$	
if $m \neq n$ $m > n$	$a(x) + b(x) = x^3 + x^2 + 10x + 14$	$x^3 + x^2 + 4$
Prod of the sequences with $o_p$	$a(x) \cdot b(x) = x^5 + 2x^4 + 5x^3 + 9x^2 + 16x^2 + 18x + 45$	
$c_i = a_i \cdot b_i$		
$d_i = \sum_{j=0}^i a_j \cdot b_{i-j}$		
$= a_0 \cdot b_i + a_1 \cdot b_{i-1} + a_2 \cdot b_{i-2} + \dots + a_i \cdot b_0$		$x^5 + 2x^4 + 3x^3 + 5x^2 + 7x + 9$

In order to do that, we will learn something about the polynomials. So what are polynomials? So they are familiar, we would write a polynomial in one variable  $x$  as  $a_0$  plus  $a_1x$  plus  $a_nx$  raise to  $n$ . So this a polynomial of degree  $n$  if  $a_n$  is not equal to 0. So let us assume that  $a_n$  is not equal to 0 and then this becomes a polynomial of degree  $n$ , okay so if think of this as a function of  $x$ , we can say that  $f(x)$  is a polynomial of degree  $n$ . So the degree of a polynomial is a largest  $d$  such that if you consider  $x$  to the power  $d$ , its coefficient is non-zero.

So largest  $d$  is such that  $x$  to the  $d$  has non-zero coefficient, so this  $a_0 a_1 \dots a_n$  is what we refer to as a coefficient. We are not really interested in evaluating these polynomials at particular points  $x$ ,

so we are just interested in the form of the polynomial. So  $x$  you can think of as a formal variable and therefore  $f(x)$  you can put it in one to one correspondence with a sequence of let us say  $n + 1$  terms. Okay so polynomial for us is now just a sequence, so a polynomial is a finite sequence of elements from a ring okay.

We will insist that these elements  $a_0, a_1$  up to  $a_n$  they are coming from a ring because we want to basically add and multiply polynomials. So let us look at these operations of sum and product, okay so you have one sequence  $a_0, \dots, a_n$  and another sequence  $b_0, \dots, b_m$ , we can just look at terms and add them. So suppose  $m$  is not equal to  $n$  and let us say  $m$  is greater than  $n$ , then we can basically pad off the other polynomial with enough number of 0s okay and then we may assume that  $m$  is equal to  $n$  and therefore the new sequence, its  $C_i$  term will be equal to  $a_i + b_i$ , okay so that is the sum.

So if you had this polynomial  $x^2 + x$  plus  $x^2 + 2x + 5$  and another polynomial  $x^3 + 8x + 9$ , so this is your 1<sup>st</sup> polynomial, let us say this is  $ax$  and this is  $bx$ . So  $ax + bx$  would basically be  $x^3 + x^2 + 10x + 14$ . And here we were looking at these coefficients and the addition of these coefficients were happening in the ring,  $8 + 2$  that gave us  $10$ ,  $9 + 5$  we got  $14$ , because we assumed that these numbers were from the ring of integers.

We could also define their product, so  $ax$  times  $bx$  would be equal to, so  $x^3$  into all these would give  $x^5 + 2x^4 + 5x^3 + 8x^2$  when you multiply you will get  $8x^3 + 16x^2 + 40x + 9x^2 + 18x + 45$ . So that can be combined and written as  $x^5 + 2x^4$  plus these terms combined to give us  $13x^3 + 25x^2 + 58x + 45$  okay.

So multiplication is little more complex operation but we are essentially looking at the coefficients and adding and multiplying the coefficients in the ring of integers okay. So formally, we could mean if you multiply this then the  $i$ <sup>th</sup> term will be, if we just denote  $c_i$  or let say  $d_i$  is a product, so  $d_i$  is equal to sum over let us say  $j$  varying from  $1$  to  $i$ , or  $0$  to  $i$ ,  $a_j b_{i-j}$ , so  $a_0$  multiplied by, that is equal to  $a_0 b_i + a_1 b_{i-1} + a_2 b_{i-2}$  all the way up to  $a_i b_0$  okay.

So the  $i^{\text{th}}$  term coefficient will be basically this, sum of products. Okay again all those operations are carried out in the (integer) in the ring of integers when we have considered this particular example, okay so now if these elements, when instead of carrying out these operations in the ring of integers, if we had to carry out these operations mod 10 okay, so instead of integers if we were considering  $\mathbb{Z}_{10}$ , then this sum would be different, mean in that case the answer would be  $x^3$  plus  $x^2$  plus 4, because  $10x$  is 0 times  $x$  and that just 0 and  $14 \bmod 10$  is going to be 4.

And if we look at the product, that will be equal to  $x^5$  plus  $2x^4$  plus  $3x^3$  plus  $5x^2$  plus  $8x$  plus 5. Okay so that is going to be a different polynomial than let us say what we do when we had considered the ring of integers. So when we are considering the arbitrary rings, the degrees I mean there some not means so the way the degree behaves is different from the usual behaviours. In the sense, if you add two polynomials, their degrees could come down.

$F[x]$

$$\begin{matrix} 2x^4 + 7x \\ \cdot \\ 5x^2 + 5 \end{matrix} \rightarrow \frac{2 \cdot 5}{0} x^6 + \frac{7 \cdot 5}{5} x^3 + \frac{2 \cdot 5}{0} x^4 + \frac{5 \cdot 7}{5} x$$

$$\rightarrow 5x^3 + 5x$$

$R[x] \leftarrow$  Polynomials in  $x$  where the coeff are from  $R$

Fact: If  $a(x) \in K[x]$  and  $b(x) \in K[x]$  are polynomials in  $P(x)$  where  $P$  is a field, then
 
$$\deg(a(x) \cdot b(x)) = \deg(a(x)) + \deg(b(x))$$

$a(x) = a_n x^n$

$b(x) = b_m x^m$

$(a_n b_m) x^{n+m}$

For example, if you take  $x^2 + 3x$  and  $9x^2 + 9x$  and if you add them, if you add them mod 10, if you are doing this mean if this is from the ring of integers mod 10 then when you sum the result would be  $10x^2$  which is 0 and plus  $12x$  and that could be, that is just  $2x$ . So suppose you had polynomials  $2x^4 + 7x$  and  $5x^2 + 5$ , if you multiply them out, the usual, the answer would be  $2 \cdot 5 x^6 + 7 \cdot 5 x^3 + 2 \cdot 5 x^4 + 5 \cdot 7 x$ , multiplication when carried out mod 10, this would give us 0, this would give us 5 and this would give us 0 and this would give us 5.

So mod 10 the answer is  $5x^3 + 5x$  okay, so we had taken a larger polynomial, mean the polynomial of larger degree and when you multiply it with some other non-zero polynomial, you are getting some result where the degree is reducing. Okay so the degree could behave in, in very funny manner. So we can take care of these kind of situations by just working in a field.

We insisted that these number, these coefficients of the polynomials were coming from a ring, (name) if you are taken these coefficients to come from a field then we can show that when you multiply two polynomials their degree cannot decrease. So let us have some notations, so if you have a ring  $R$  and if you look at polynomials whose coefficients comes from  $R$ , then we will write it as  $R[x]$ . So this is the notation for polynomials in  $x$  where the coefficients are from  $R$ .

And if we have a field, we might usually write it as  $F[x]$  to indicate the difference between a ring and a field. Okay so when we say  $F[x]$  or  $R[x]$  it means, we are considering polynomials in the variable  $x$  and the coefficients are coming from  $R$  or  $F$ . Okay so if we have  $a$ , if we have polynomials, if we consider the polynomials, where the coefficients are from a field then we will have the following observation.

If  $a(x)$  and  $b(x)$  are polynomials in  $F[x]$  where  $F$  is a field then degree of  $a(x)$  times  $b(x)$  is equal to degree of  $a(x)$  plus degree of  $b(x)$ . Okay we should assume that  $a(x)$  is not equal to 0 and  $b(x)$  is not equal to 0 because if they were 0 and you take the product, we will get 0. So if they are non-zero polynomials then the degree is add up, easy to check. So if  $a(x)$  is a polynomial and if its degree is  $m$  and there is a term  $a_m x^m$  and in  $b(x)$  there is a term  $b_n x^n$  and then you take the product is going to be this term  $a_m$  times  $b_n$  into  $x^{m+n}$ .

And since  $a_m$  and  $b_n$  are coming from a field and they are non-zero elements of the field, they cannot multiply to give us 0 elements. So  $x^{m+n}$  will have a non-zero coefficient and that is  $m+n$  is going to be the largest term and therefore I mean it is the term of the highest degree and therefore the degree of the product would be equal to  $m+n$ . Okay So we will stop here and continue in the next class.
