Lecture – 31
Recurrence Relations

So, we have read the recursion and the recursively defined sets, functions, sequences and we have also learned that how to design the recursive algorithms. Today will read the Recurrence Relation, which is very much related to this recursion. And will see that, how given a sequence that each term is related to others and how we can get a explicit formula, how we can get a recurrence relation with that thing and how to solve or what do you mean by solution. So, will do that framing recurrence relation and solving recurrence relations will read the recurrence relations.

(Refer Slide Time: 01:20)

Recurrence Relations

A recurrence relation for the sequence a_0, a_1, \dots, a_n is an equation that relates a_n to certain of its predecessors, a_0, a_1, \dots, a_{n-1} .

Fibonacci Sequence.

n^{th} fibonacci no. $f_n = f_{n-1} + f_{n-2}$; $f_0 = 0, f_1 = 1$

example of recurrence relation.

So, first we define a recurrence relation, I can write that a recurrence relation for the sequence, we have earlier read the sequence or recursively defined sequences. So, for the consequence a_0, a_1 to a_n having n number of sequence. It is an equation that relates a_n to certain of its predecessors and the predecessors are a_0, a_1 up to a_{n-1} .

So, recurrence relation gives a relation that how a_n is related to its predecessors. Now we have already read many sequences where this relation exists. So, one popular example is that Fibonacci sequence, how we define that Fibonacci. So, for Fibonacci

sequence we know that nth Fibonacci number f_n is a function of f_{n-1} and f_{n-2} . Some initial conditions are given that $f_0 = 0$ and $f_1 = 1$.

So, this is an example of a recurrence relation because, f_n is related to its predecessors f_{n-1} and f_{n-2} with some addition and these are my initial conditions. So, this is an example of recurrence relation, we taken example of compound interest, how to compute the compound interest, we take one example.

(Refer Slide Time: 05:17)

Example 2 A person invests Rs. 10,000/- @ 15% interest compounded annually.
 At the end of n^{th} year,

$$A_n = A_{n-1} + 0.15 A_{n-1}$$

$$= (1.15)^n A_{n-1} \quad \text{--- Recurrence Relation}$$

$$n=3, \quad A_3 = (1.15) \times A_2$$

$$= (1.15)^2 \times A_1$$

$$= (1.15)^3 \times A_0; \quad A_0 = 10000$$

$$= (1.15)^3 \times 10000$$

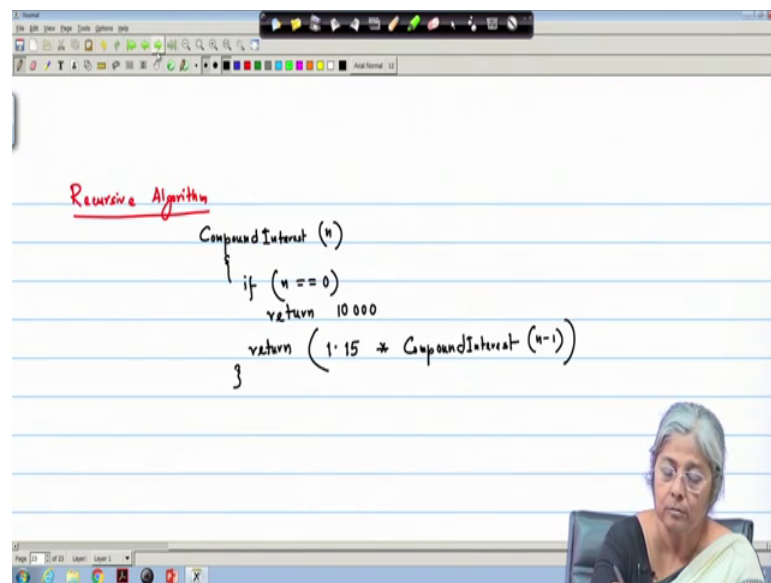

$$A_n = (1.15)^n \times 10000 \quad \text{--- Explicit Formula}$$

Example 2, see person invests rupees 10000 at the rate of say 15 percent interest, which is compounded annually. Now we want to find out the total amount at the end of n th year. So, we can write the amount that the at the end of n th year, we can get that A_n is A_{n-1} that amount that at the end of $n-1$ th year plus the interest; that means, it is 15 percent. So, 15% into A_{n-1} . So, I can write this is 1.15 into A_{n-1} . So, here A_n relates to only 1 predecessors A_{n-1} in this wait 1.15 into A_{n-1} . So, this is a recurrence relation, this is a recurrence relation.

Now, if I take that n equal to 3 see n equal 3. So, A_3 is 1.15 into A_2 , I can write 1.15 into again it is 1.15 we want. So, this is square A_1 is 1.15 cube into A_0 . Now what is my A_0 ? Because at the beginning it in 10 rupees 10000 was invested; so, it is 10000. So, I can write that it is 1.15 cube into 10000. So, I can generalize this thing as that A_n equal to 1.15 whole to the power n into 10 10000 and we call this is a explicit formula, this is

an explicit formula or of n . So, this is my recurrence relation, where the n th term, how it is it gives a relation, how it is related to the predecessors and it gives directly; that means, it is a function of n explicit formula. Now, we have read the recursive algorithm also.

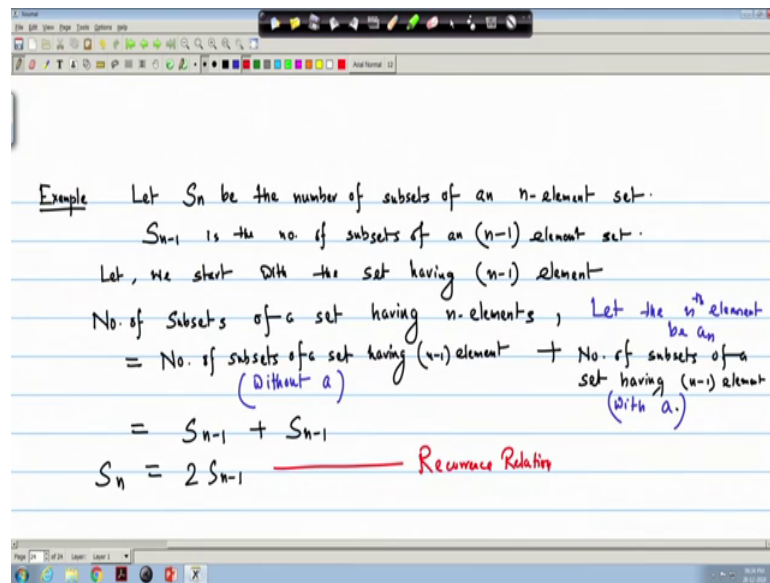

(Refer Slide Time: 09:48)

So, the same for the same example, I can write the recursive algorithm that, I can write the function that if it is compound interest n ; that means, at the end of n th year. Now if n equal to 0; that means, it is my initial condition or the terminating step then return 10000 else it will return that compound interest delete 1.15 into compound interest n minus 1.

So, with this simple example, you see that what that we get the recurrence relation explicit formula and this recurrence relation; that means, the recursive step that if we give a code of that then it gives you as the recursive algorithm on that thing. Now, we take another simple example, but it is very important when will see the will try to solve the recurrence relation.

(Refer Slide Time: 11:50)

So, earlier we have read one example of set that say let S_n be the number of subsets of an n element set then how can I give a recurrence relation for a set, if we remember that see S_n be the number of subset then S_{n-1} is the number of subsets of an $n-1$ element set.

So, let initially I have let we start with the set, we start with the set having $n-1$ element. Now if I get 1 element to that set. So, that it becomes an n element set then what will be the number of subsets? So, the number of subsets of a set having n elements, I can write this equal to the number of subsets having $n-1$ elements subsets of a set having $n-1$ element plus, if I add one more element to all the subsets of this $n-1$ elements; that means, this is if I let the n^{th} element be let the n^{th} element be a or a_n .

So, number of subset of a set having $n-1$ element, which is without a and here I can write the number of subsets of a set having $n-1$ element with a , this is with a . Now clearly this is my S_{n-1} and this is also S_{n-1} only difference is here, in these subsets a was not there and in this subsets S is there. So, this becomes $2 S_{n-1}$. So, $S_n = 2 S_{n-1}$, this is my recurrence relation, this is my recurrence relation.

(Refer Slide Time: 17:23)

$$\begin{aligned} S_n &= 2 S_{n-1} \\ &= 2 \cdot 2 \cdot S_{n-2} \\ &= 2 \cdot 2 \cdot 2 \cdot S_{n-3} = 2^3 S_{n-3} \\ &\vdots \\ &= 2^n S_{n-n} \\ &= 2^n S_0 \quad S_0 = 1 \end{aligned}$$

$S_n = 2^n$ ——— Explicit formula

The no. of subsets of a set having n elements

Now, we can get the explicit formula also for this example, if I start with that S_n equal to $2 S_{n-1}$ is 2 into $2 S_{n-2}$ is 2 into 2 into 2 into S_{n-3} . In that way, if I continue I will be getting that 2 to the power n , which is here 2^3 into S_{n-3} , this is actually 2^3 into S_{n-3} . So, I can get 2 to the power n S_{n-n} is 2 to the power n is 0 and or S_0 is 1 , which is the empty set, this is 2 to the power n .

So, S_n is 2 to the power n and this is my explicit formula, for the number of subsets S_n is the S_n is the number of subsets of a set having n elements. So, we see that how we can frame the recurrence relation and we get a explicit formula actually, this explicit formula is called the solution and the solution that which satisfies the sequences, we get. Now we get another example we see.

(Refer Slide Time: 19:19)

Find the Recurrence Relation

Example 3 for the number of n -bit strings that do not contain '111'

Let S_n be the no. of n -bit strings that do not contain '111'

S_{n-1} be the $(n-1)$ bit string that do not contain '111'

How S_n is related to $S_{n-1}, S_{n-2} \dots$

We can get S_n

1. no. of strings begin with '0'
2. no. of strings that begin with '10'
3. no. of strings that begin with '110'

$S_3 = 7$ (000, 001, 010, 011, 100, 101, 110, 111) 111

$S_n = S_{n-1} + S_{n-2} + S_{n-3}$; $S_1 = 2$ (0, 1), $S_2 = 4$ (00, 01, 10, 11), $S_3 = 7$

So, we find the number of the bit n bit strings, find the number of n bit strings that do not contain 1 1 1 say, a particular bit pattern is not there then how to solve or how to get this number. So, let the solution is let S_n be the number of n bit strings that do not contain 1 1 1 pattern. Now we want to find out the recurrence relations actually here, that example will be that find the find the recurrence relation, because first we try to frame the recurrence relation, how to frame the recurrence relation.

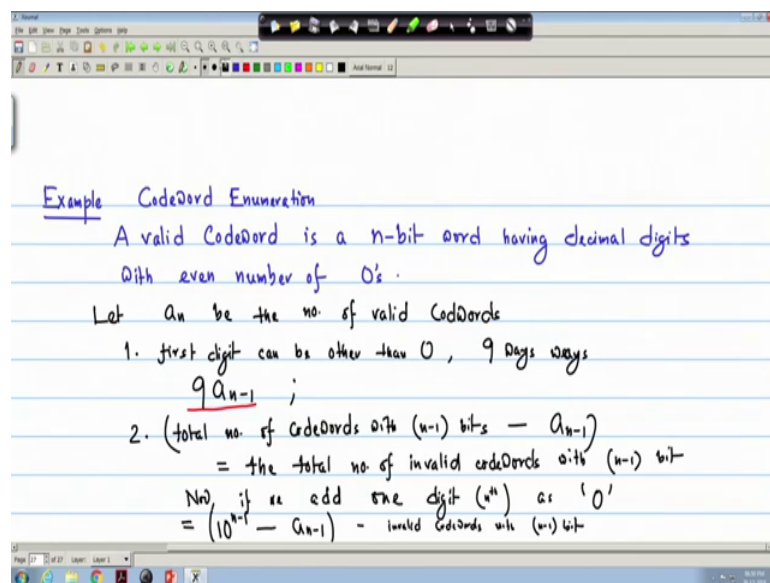

So, our problem is find the recurrence relation, where for the number of n bit strings, but we write for the number of n bits string that do not contain 1 numbers. Now let S_n be the number of n bit strings then; obviously, S_{n-1} be the n minus 1 bit string that do not contain 1 1 1. And then similar thing, where is n minus 2 is n minus 3 like that then how we can get because, recurrence relations we have defined that a particular term, how it is related to it is predecessors; that means, here how S_n how S_n is related to it is predecessors bit S_{n-1}, S_{n-2} and so on.

Now, how we can find S_n because, it should not contain 1 1 1. So, I can get S_n . So, I can get S_n that will found that that it is the strings the number of strings that begin with 0, number of strings that begin with 0 because, it they do not contain 1 1 1. So, if it begins with 0. So, then it will not contain the 1 pattern then number of strings that begin with 1 0 then also it is violated number 3 is the number of strings that begin with 1 1 0 says that 1 1 1, it does not consider.

So, I can write that expression that S_n , I can write S_n equal to S_{n-1} . For the first case, then S_{n-2} plus S_{n-3} then what will be my initial conditions? My initial conditions will be S_1 equal to 2 since, only 1 bit S_1 that it will it can be only 0 and 1. So, it is 2 then what will be my S_2 ? S_2 will be 4, because these will be 00, 01, 10, 11. Similarly, I can get S_3 equals to 11, I can get S_3 equal to 7 because here, it will be 000, 001, 010, 011, 100, 101 and 110, but 111 will not be here, these will not be here because so, it has 7.

So, the initial conditions that S_1 equal to 2 S_2 equal to 4 and S_3 equal to 7, I get the recurrence relation that is n equal to S_{n-1} plus S_{n-2} plus S_{n-3} . So, I can frame the recurrence relation for S_n , which is the which represent the n bit string that do not contain 111. Now we can see that a different type of examples normally, it is very important that we call that a codeword enumeration.

(Refer Slide Time: 27:15)

So, we take another example of codeword enumeration. Say a code a valid codeword so, a valid codeword is a some n bit word having decimal digits with even number of 0's. So, it is defined like even number of 0's, now we have to find the codeword. So, let a n be the number of valid codewords then, how we can get a relation or a recurrence relation? So, I can write that a n and here also I can get set, how we can get the recurrence relation of the n or how we can found the number of valid codewords? So, it

can be the first word, first letter or the first digit can be other than 0. So, there are 9 such digit, digits can be there.

So, 9 ways I can do that thing, we can do and how many such we can get. So, this going to be $9 \cdot a_{n-1}$, because $n-1$ is again a valid code word; that means, we consider $n-1$ is the $n-1$ bit words having even number of 0's and other way other things, we can get that the total number of codewords. So, if I can add a 0 total number of code words having $n-1$ bits. So, total number of codewords with $n-1$ bits minus a_{n-1} , the valid codeword. So, it will give me the total number of it will give me the total number of invalid codewords, the total number of invalid codewords with $n-1$ bit.

Now, if we add 1 digit the n th digit say the n th digit as 0 then I will get a valid codeword, I will get a valid codeword. So, I can tell that these nine a_{n-1} and these total number, what will be that number? We can see that, these number total number will be the actually give me the n . Now, what is this number? This number will be we know that since, I have 10 digits. So, these will be 10 to the power $n-1$ is the total number of codewords minus valid codewords is $n-1$. So, this is number of a invalid codewords, this is invalid code words with $n-1$ bit and n th bit we add a 0.

(Refer Slide Time: 33:49)

The image shows a handwritten derivation of a recurrence relation on a whiteboard. The equations are as follows:

$$a_n = 9a_{n-1} + (10^{n-1} - a_{n-1})$$

$$= 8a_{n-1} + 10^{n-1} \quad \text{Recurrence Relation.}$$

$$a_1 = 9$$

$$a_2 = 8 \cdot 1 + 1 = 82$$

So, n becomes a_n is $9 \cdot a_{n-1}$ plus 10 to the power $n-1$ minus a_{n-1} and this gives me $8 \cdot a_{n-1}$ plus 10 to the power $n-1$, this is my recurrence relation

then what is the initial condition? This is my recurrence relation. We can get that for a 1 the initial condition is that a_1 equal to 9 and a_2 equal to some 81 plus. So, 10 to the power 0 is 1 that we can validate that it is equal to 82. So, you see a different type of examples and how we can frame or how we can design the recurrence relation for those problems; that means, given sequence that how a 1 term is related to the previous terms. So, next class we will see, how it can solve the recurrence relations.
