**Closure Properties of Relation Continuation**

So we were considering the reflexive closure of a, binary relation, symmetric closure and transitive closure. Let us recall the definition.

(Refer Slide Time: 1:14)

Let  $R$  be a binary relation on a set  $A$ , the reflexive closure of  $R$  is the relation  $R$  dash such that  $R$  dash is reflexive,  $R$  dash contains  $R$ , for any reflexive relation  $R$  double dash if  $R$  double dash contains  $R$ , then  $R$  double dash contains  $R$  dash. That is the reflexive closure of a relation.  $R$  is the smallest reflexive relation containing  $R$ . Similarly, we can define symmetric closure and transitive closure. As a graph we have seen that if you have binary relation represented by a graph, to get the reflexive closure we have to add the self loops at every node and to get the symmetric closure if there is an arc in one direction you must add the arc in the other direction. To get the transitive closure if there is a path between some nodes then you have to add the arc corresponding to the path. This is what we have seen in a rough manner and we considered the reflexive closure.

(Refer Slide Time: 2:33)

Let  $R$  be a binary relation on a set  $A$ .  
Then  $r(R) = R \cup E$ .

Definition :: Let  $R$  be a binary relation from  $A$  to  $B$ .  
The converse of the relation  $R$ , denoted  $R^c$ , is the binary relation from  $B$  to  $A$  defined as follows:  
 $R^c = \{ \langle y, x \rangle \mid \langle x, y \rangle \in R \}$

If  $D$  is the digraph of the relation  $R$ , the digraph of  $R^c$  can be constructed from  $D$  by reversing the direction of all the arcs of  $D$ .

Let  $R$  be a binary relation on the set  $A$  then reflexive closure of  $R$  is denoted by  $R$  union  $E$ . Then we have also seen what is meant by the converse of a relation. If  $R$  is a, binary relation whenever you have a pair  $x, y$  in  $R$  you have the pair  $y, x$  in  $R$  power  $c$ .

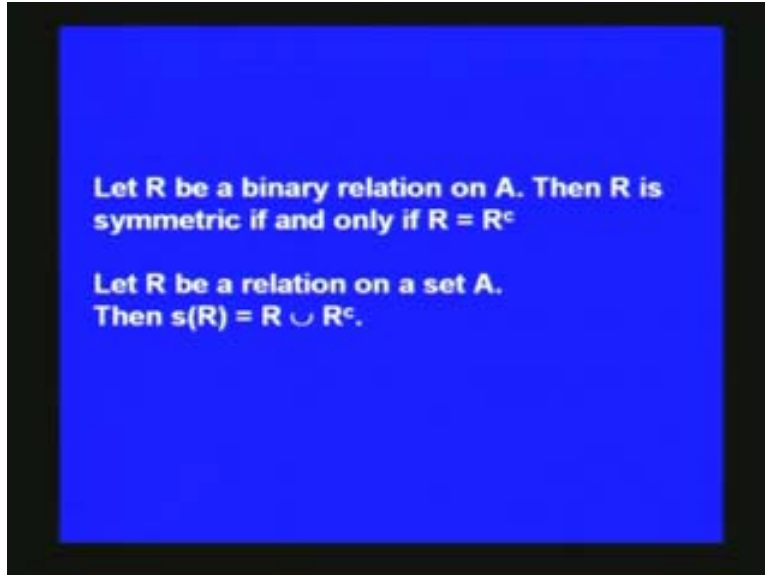

(Refer Slide Time: 3:00)

Let  $R, R_1$ , and  $R_2$  be binary relations from  $A$  to  $B$ .  
Then each of the following holds.

- (a)  $(R^c)^c = R$
- (b)  $(R_1 \cup R_2)^c = R_1^c \cup R_2^c$
- (c)  $(R_1 \cap R_2)^c = R_1^c \cap R_2^c$
- (d)  $(A \times B)^c = B \times A$
- (e)  $\phi^c = \phi$
- (f)  $(\overline{R})^c = \overline{(R^c)}$ , where  $\overline{R}$  denotes  $(A \times B) - R$ .
- (g)  $(R_1 - R_2)^c = R_1^c - R_2^c$
- (h) If  $A = B$ , then  $(R_1 R_2)^c = R_2^c R_1^c$
- (i)  $R_1 \subset R_2 \Rightarrow R_1^c \subset R_2^c$

Then we also considered some properties of converse relations.

(Refer Slide Time: 3:05)

This also we have already seen, if  $R$  is a binary relation on a set  $A$  then  $R$  is symmetric if and only if  $R$  is equal to  $R$  power  $c$ . Now, let us consider this portion, how do you define the symmetric closure? What is the symmetric closure of binary relation  $R$ ? Let  $R$  be a binary relation on the set  $A$  then the symmetric closure of  $R$  is  $R$  union  $R$  power  $c$ .  $R$  is a binary relation on a set  $A$  then the symmetric on  $A$  the symmetric closure of  $R$  is given by  $R$  union  $R$  power  $c$ .

How do you prove? What is the symmetric closure?

The symmetric closure should contain  $R$  it should be symmetric and any other symmetric relation should contain the symmetric closure of  $R$ . suppose  $R$  dash is equal to  $R$  union  $R$  power  $c$  then we have to show that symmetric closure is  $R$  dash the symmetric closure of  $R$  is  $R$  dash. Now what are properties of  $R$  dash?  $R$  dash contains  $R$  this is the first property that is true and  $R$  dash is symmetric why, because look at this result,  $R$  is symmetric if and only if  $R$  is equal to  $R$  power  $c$ . Now what can you say about  $R$  union  $R$  power  $c$  the converse of this by the results you have seen earlier let us see  $R_1$  union  $R_2$  power  $c$  is  $R_1$  power  $c$  union  $R_2$  power  $c$ . Making use of this property  $R$  union  $R$  power  $c$  is  $R$  power  $c$  union  $R$  and that is nothing but  $R$  power  $c$  union  $R$ . So the converse of this is equal to this so  $R$  dash is symmetric.

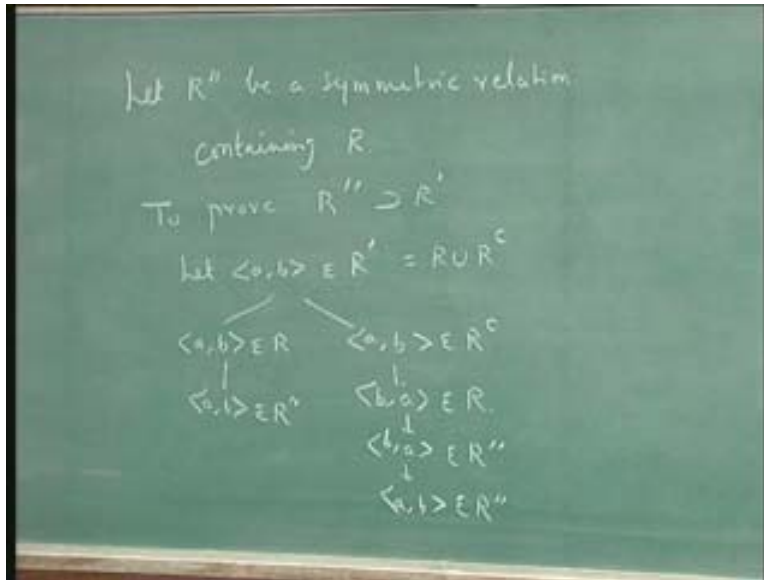

(Refer Slide Time: 05:27)

Handwritten mathematical derivation on a chalkboard:

$$R \text{ on } A$$
$$s(R) = R \cup R^c$$
$$R' = R \cup R^c$$
$$R' \supset R \quad \checkmark$$
$$R' \text{ is symmetric } \checkmark$$
$$(R \cup R^c)^c = R^c \cup (R^c)^c$$
$$= R^c \cup R$$

Now the third part is, let  $R$  double dash be a symmetric relation containing  $R$ . Then we have to prove  $R$  double dash contains  $R$  dash. Now let  $a, b$  belong to  $R$  dash. What is  $R$  dash?  $R$  dash is  $R$  union  $R$  power  $c$ . So if  $a, b$  belongs to  $R$  dash there are two possibilities  $a, b$  belongs to  $R$  or  $a, b$  belongs to  $R$  power  $c$ . Now  $R$  double dash contains  $R$  so  $a, b$  belongs to  $R$  means  $a, b$  will belong to  $R$  double dash because  $R$  double dash is a symmetric relation containing  $R$  so if  $a, b$  belongs to  $R$   $R$  double dash will contains that pair so  $a, b$  belongs to  $R$  double dash. Now, if  $a, b$  belongs to  $R$  power  $c$  what does that mean?  $b, a$ , belongs to  $R$  and because  $R$  double dash contains  $R$  from this you will conclude  $b, a$ , belongs to  $R$  double dash but  $R$  double dash is a symmetric relation so from this you conclude  $a, b$  belongs to  $R$ . So whenever you take a pair  $a, b$  belonging to  $R$  double dash it also belongs to  $R$  double dash so  $R$  double dash contains  $R$  dash. So the third property also satisfied so the symmetric closure of a relation is given by  $s(R)$  is equal to  $R$  union  $R$  power  $c$ .

(Refer Slide Time: 07:30)

Now, let us consider the transitive closure. What is the transitive closure? When we you have a path as when you represent a relation as a graph when you have path between some nodes a transitive closure will contain the R between the two nodes. This is the idea of a transitive closure. We have already seen that in a, communication network if direct connection is denoted by an arc then the transitive closure represents all the pairs of nodes by which from the first node you can send the communication to the second node. This transitive closure has lots of practical applications. Now the transitive closure is given by this.

(Refer Slide Time: 08:36)

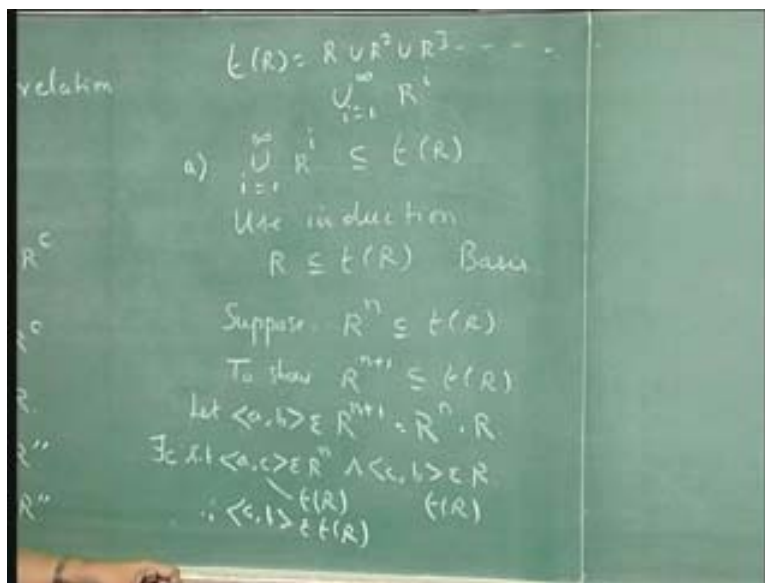

Let R be a, binary relation on the set A then the transitive closure of R is union i is equal to 1 to infinity R power i that is equal to R union R squared union R cubed union etc.

Now, we have to prove this equality, that is  $t(R)$  is equal to  $R \cup R^2 \cup R^3 \cup \dots$  and this you represent  $i$  is equal to  $1$  to infinity  $R^i$ . Now, we will prove it in two parts, first this is contained in this and then this is contained in this, so first part is we prove that  $\bigcup_{i=1}^{\infty} R^i$  is contained in  $t(R)$  this is what we have to prove. Now to prove this part use induction  $R$  is contained in  $t(R)$  by definition because the definition of  $R$  is, if it contains  $R$  it is transitive and it is the smallest such relation this is the basis clause. Now, the induction portion also suppose  $R^n$  belongs to  $t(R)$  to show  $R^{n+1}$  belongs to  $t(R)$  this is the induction portion of it.

Now, let  $a, b$  belong to  $R^{n+1}$  that is  $R^n \circ R$  when can you say that  $a, b$  belongs to  $R^{n+1}$ ? When there exist  $c$  such that  $a, c$  belongs to  $R^n$  and  $c, b$  belongs to  $R$ . When you say  $a, b$  belongs to  $R^{n+1}$  that means there should be  $c$  in  $A$  these are all defined on a set  $A$  so  $a, c$  belongs to  $R^n$  and  $c, b$  belongs to  $R$ . now, by induction hypothesis this belongs to  $t(R)$  and this also belongs to  $t(R)$  because anyway  $R$  is contained in  $t(R)$  so  $a, c$  belongs to  $t(R)$  and  $c, b$  also belongs to  $t(R)$  but  $t(R)$  is a transitive relation  $t(R)$  is transitive therefore  $a, b$  belongs to  $t(R)$ . So we have seen that if you assume  $R^n$  belongs to  $t(R)$   $R^{n+1}$  also belongs to  $t(R)$  so union of  $i$  is equal to  $1$  to infinity  $R^i$  is contained in  $t(R)$ . So we have proved this portion.

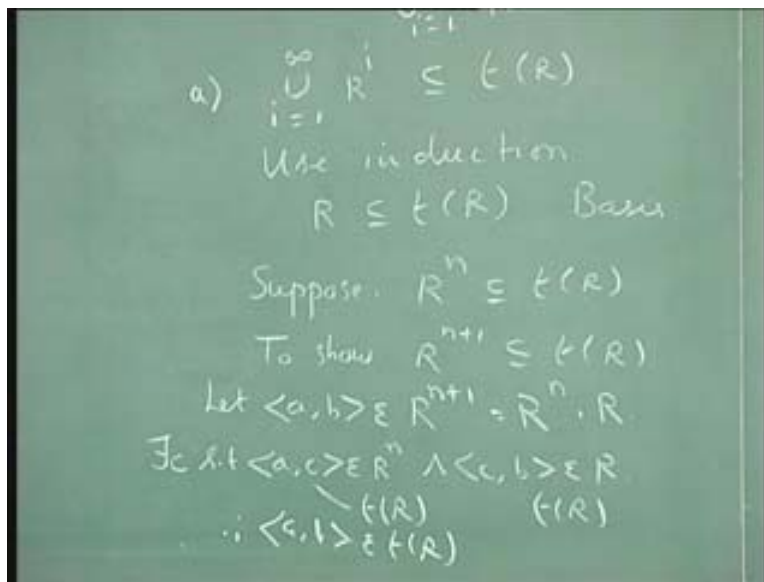

(Refer Slide Time: 11:59)

The other way around we have to show that  $t(R)$  is contained in union of  $i$  is equal to  $1$  to infinity  $R^i$  this is second portion. How do you prove that? First you prove that union of  $i$  is equal to  $1$  to infinity  $R^i$  is transitive, how to prove this? Suppose you have  $a, b$  belonging to some  $R^s$  and then  $b, c$  belongs to some  $R^t$   $a, b$  belongs to  $R^s$  means  $a, b$  belongs to this union;  $b, c$  belongs to  $R^t$  it also belongs to this. Now what can you say about  $a, c$ ? In that case  $a, c$  will belong to  $R^s \circ R^t$  that is equal to  $R^{s+t}$  that is equal to  $R^s \cup R^{s+1} \cup \dots \cup R^{s+t}$  that is equal to  $R^s \cup R^{s+1} \cup \dots$  that is equal to  $\bigcup_{i=1}^{\infty} R^i$ .

That is  $a, c$  will also belong to union of  $i$  is equal to 1 to infinity  $R$  power  $i$ . so when you have two pairs  $a, b$  and  $b, c$  belonging to this you also have  $a, c$  belonging to this and when this condition is satisfied you say that the transitive property is satisfied. So, we have proved that  $i$  is equal to 1 to infinity  $R$  power  $i$  is transitive. And  $i$  is equal to 1 to infinity  $R$  power  $i$  obviously it contains  $R$  power 1 so this is a transitive relation containing  $R$ . And by the definition of  $t(R)$   $t(R)$  is contained in any transitive relation containing  $R$ . It is the smallest transitive relation. So this is the transitive relation containing  $R$  and by definition of  $t(R)$  any transitive relation containing  $R$  should contain  $t(R)$  so we get this result  $t(R)$  is contained in union of  $i$  is equal to 1 to infinity  $R$  power  $i$ . So these  $a$  and  $b$  together give us this result.

(Refer Slide Time: 14:44)

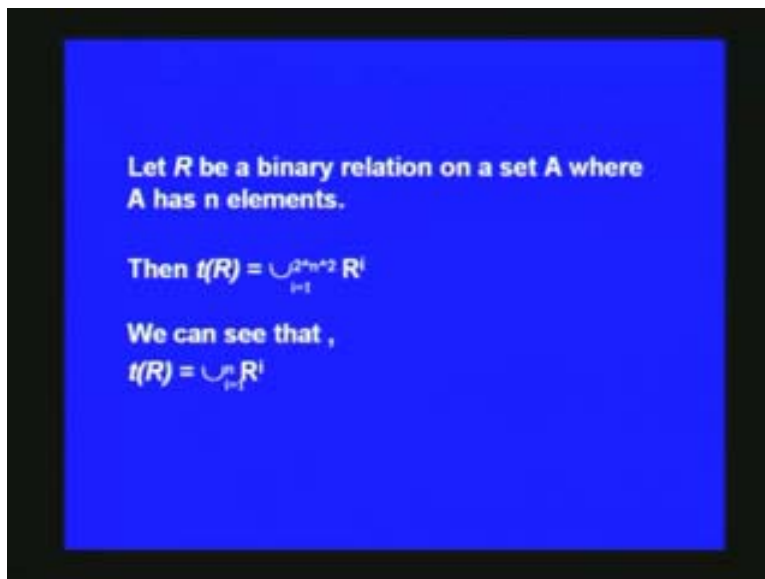

That is  $t(R)$  is equal to union of  $i$  is equal to 1 to infinity  $R$  power  $i$   $R$  union  $R$  squared  $R$  cubed etc. let us consider some examples. Consider the set of non negative integers and a relation  $R$  such that  $x$  is related to  $y$  if  $y$  is equal to  $x$  plus 1. That is any number  $i$  will be related  $i$  plus 1 define  $R$  like that on natural numbers, what is the transitive closure of this? What is the transitive closure of  $R$ ? Now, we have seen that  $R$  squared means  $x$  will be related to  $x$  plus 2 for any  $x$ ;  $R$  power  $s$  is  $x$  is related to  $x$  plus  $s$  and so on and  $t(R)$  is union of  $i$  is equal to 1 to infinity  $R$  power  $i$  so what is that relation it is less than relation so  $t(R)$  is the less than relation.

(Refer Slide Time: 16:09)

Now, if you have this relation set of human beings then  $R$  denotes the relationship  $x$  related to  $y$ .  $x$  is the child of  $y$  then what is the transitive closure? What is the  $t(R)$ ? This is the relation this represents a relation  $x$  is the descendant of  $z$   $x t(R) z$  means  $x$  is the descendant of  $z$ .

(Refer Slide Time: 17:29)

Now what about this?  $n$  we have considered this infinite set what about the finite set? Let  $R$  be a binary relation on a set  $A$  where  $A$  has  $n$  elements. Then you can show that  $t(R)$  is equal to union of  $i$  is equal to 1 to  $2^n - 1$   $R^i$  where  $R$  is a binary relation on a set  $A$  and  $A$  has  $n$  elements where  $n$  is a finite number. Earlier we have seen that with  $n$

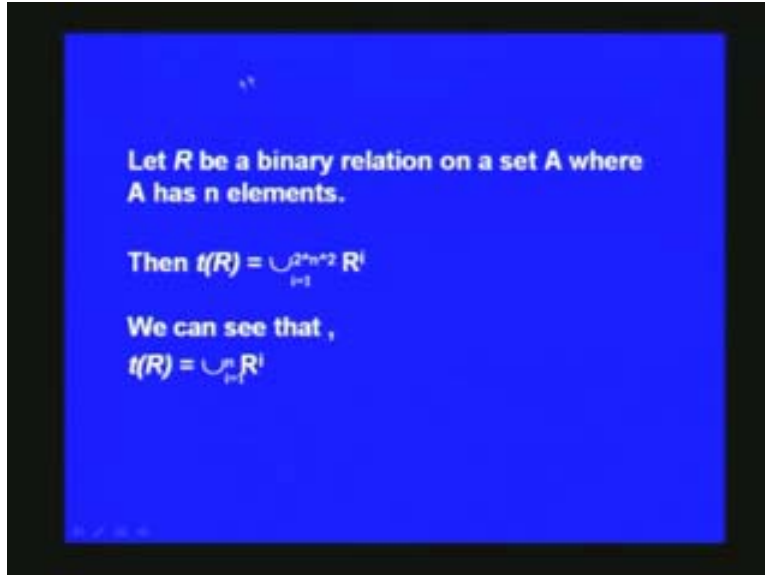

elements if you look at it as a graph you can see that with  $n$  elements you have a graph if its a relation the ordered pairs will be represented by arcs so you can have maximum  $n$  squared arcs in such a graph that the maximum number of ordered pairs in a relation is  $n$  squared and any relation you can have each one of the pair present or not present, there are two possibilities there can be maximum  $n$  squared pairs and each one of them may be present or may not be present in a relation so that gives you  $2$  power  $n$  squared possibilities so maximum you can have two power  $n$  squared distinct relation on  $A$ . So this  $R$  power  $R$ ,  $R$  power  $0$  is the equality relation that we are not bothered about now, in transitive closure we start from  $1$  to  $1$ . So if you consider  $R$ ,  $R$  squared,  $R$  cubed etc up to  $R$  power  $2$   $n$  squared  $R$  power  $2$  power  $n$  squared plus  $1$  among this set this will get repeated so you can at the most  $2$  power  $n$  squared distinct relation. If you consider  $R$  power  $2$  power  $n$  squared plus  $1$  this will be one of these relations only. So it is not necessary to consider more than this.

(Refer Slide Time: 20:08)

So  $t(R)$  is given by this,  $t(R)$  is union of  $i$  is equal to  $1$  to  $2$  power  $n$  squared  $R$  power  $i$ .

(Refer Slide Time: 20:20)

Not only that you can see that in this case  $t(R)$  is union of  $i$  is equal to 1 to  $n$   $R$  you need not even consider up to when  $n$  is finite when the underlined set is a finite set  $t(R)$  you have to consider only  $i$  is equal to 1 to  $n$   $R$  power  $i$ , why? You can see that  $t(R)$  is nothing but  $i$  is equal to 1 to  $n$  you need not even consider up to  $i$  is equal to  $2$  power  $n$  squared it is enough if you consider up to  $n$ , why because what is really  $t(R)$  is it transitive closure? That means if  $R$  is represented by a directed graph like this that is in  $t(R)$  any path you also have an arc that is  $t$ . Now, any path in  $R$  power  $2$  power  $n$  squared if an element is  $R$  power  $i$  if ordered pair  $x, y$  is in  $R$  power  $i$  that means between  $x$  and  $y$  there is a path of length  $i$  that is what it means. Now this is  $R$ , we will consider the transitive closure but before that if this represents  $R$   $x, y$  is an ordered pair in  $R$  power  $i$  means in  $R$  there is a path between  $x$  and  $y$  of length  $i$ .

(Refer Slide Time: 22:07)

Now, if you have a path between two nodes if you have a path between two nodes something like this from  $x$  to  $y$  directed path remove all the cycles from that remove still there is a directed path from  $x$  to  $y$ . Earlier we had a path like that a directed path which was not simple like this, now remove the cycles from this then you get a directed simple path from  $x$  to  $y$ . so whenever there is a path between  $x$  and  $y$  directed path between  $x$  and  $y$  you can get a simple path between  $x$  and  $y$  by removing the cycles and what can say about the length of this simple path? Even if it visits all the nodes and comes back to  $x$  it will be of length  $n$  only. So the length of such a simple path will be at the most  $n$  when you have  $n$  elements in  $A$ .

(Refer Slide Time: 23:24)

So we need not even consider up to  $2^n$ , it is enough if you consider  $i$  is equal to 1 to  $n$ . So in the definition of  $t(R)$  whenever there is a directed path it should be replaced by an arc. But we know that if you have the directed path by removing the cycles you can get a simple path between  $x$  and  $y$  of length less than or equal to  $n$  so you can add the arc in the transitive closure. So  $t(R)$  is nothing but  $\bigcup_{i=1}^n R^i$ . This gives us a very simple procedure to find the  $t(R)$ .

Now we have already seen that, take that simple one, simple binary relation having just two paths, so what is the transitive closure of  $R$ ? This is  $R$  and what will be the transitive closure of  $R$ ? Whenever there is a directed path you have to add the arc so the transitive closure will be this  $a, b, c$ . Now, if you represent the adjacent matrix of  $R$  like this what will be  $a, b, c$ ? What will be the adjacency matrix?  $a$  to  $b$  there is an arc,  $b$  to  $c$  there is an arc so this is the adjacency matrix of  $R$ . Suppose I denote this by  $A$  then what can I say about  $A$  squared?

What can you say about  $A$  squared? It is  $\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$  cross  $\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$ . If you multiply what do you get? Here  $\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$  cross  $\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$  this multiplied by this is again  $\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$  this multiplied by this will give you 1 and the rest of the element this multiplied by this is 0 this multiplied by that is also 0 and so on. So  $R$  squared represent  $A$  squared. Now if you consider the graph or the binary relation  $a, b, c$  this is  $R$ ,  $R$  squared consists of only one arc between  $a$  and  $c$  any path of length of two is replaced by an arc so  $R$  squared has this which is represented by this matrix. Now what about  $R$  cubed? In  $R$  cubed there is no path of length three so  $R$  cubed is the empty relation that is obtained by multiplying  $R$  cubed is  $R$  squared cross  $R$  so that is obtained by multiplying this the matrix representing  $A$  squared and  $A$  that is  $\begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}$ . So if you multiply you will see that that is the 0 matrix.

(Refer Slide Time: 27:18)

So we see that R which is this is represented by 0 1 0, 0 0 1, 0 0 0. And R squared is a, b, c and this is represented by 0 0 1, 0 0 0, 0 0 0. R cubed is just empty relation and represented by the 0 matrix. So the transitive closure of R is R union R squared union R cubed union of i is equal to 1 to n R cubed that is you find the union of these three matrices you will get 0 1 1, 0 0 1, 0 0 0 and that is nothing but this a, b, c if you represent there is an arc from a to b, there is an arc from a to c, there is an arc from b to c this is the transitive closure. So you get the transitive closure by matrix multiplication like that.

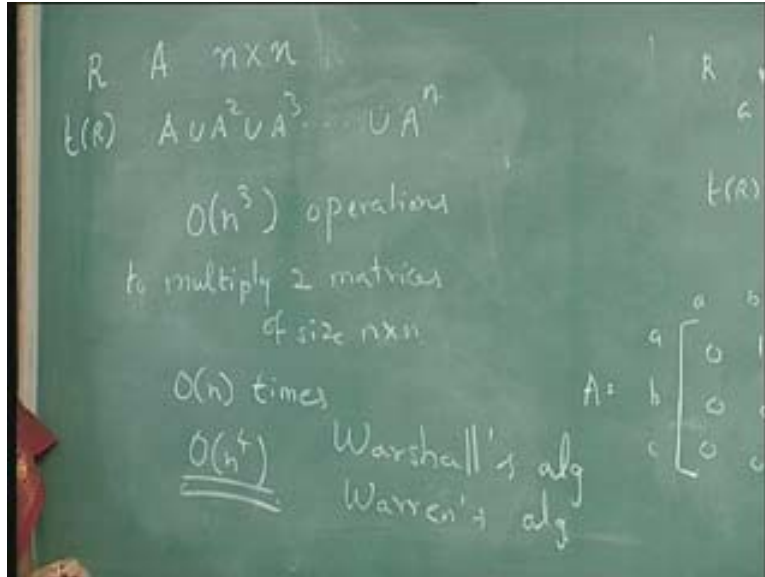

(Refer Slide Time: 29:03)

How much time it will take to calculate the transitive closure?

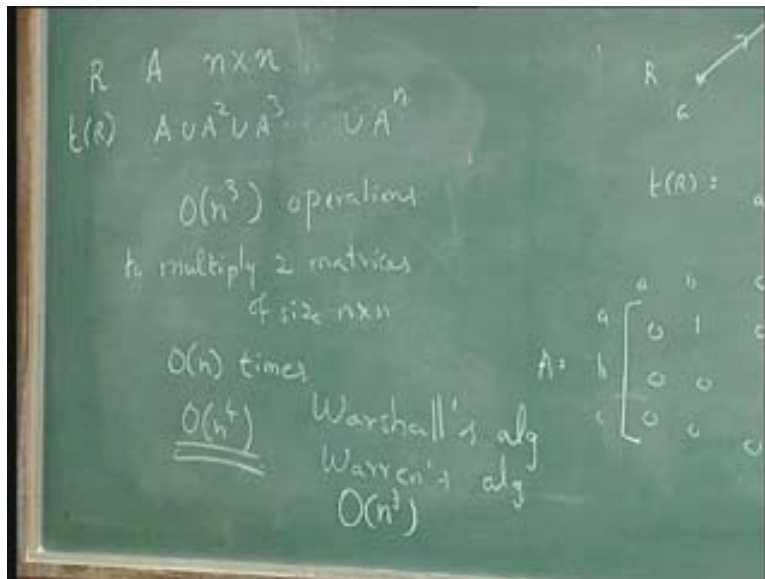

So R is a binary relation represented by the adjacency matrix and this is of size n by n. Then to calculate the transitive closure of R you have to find A, A squared, A cubed up to A power n. how much time it will take? To multiply two matrices of size n by n you require order n cubed operations. Like that you are multiplying once, twice, thrice like that n minus 1 times actually so you are performing this matrix multiplication order n times, order n times this matrix multiplication is performed. So totally it will take order n power 4 of course addition will take some time but the total time is, this is the predominating factor so order n power 4 time it will take to find the transitive closure of a relation.

(Refer Slide Time: 31:26)

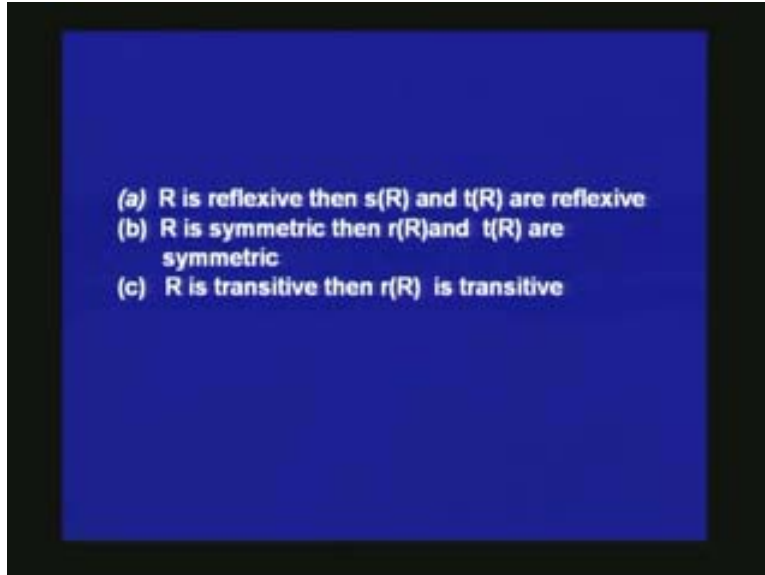

There are very good algorithms to find the transitive closure like the Warshall's algorithm and Warren's algorithm may be we shall consider them later they are very good algorithms very efficient algorithms for calculating transitive closure they are very simple also they take only order  $n$  cubed time to find the transitive closure.

(Refer Slide Time: 31:40)

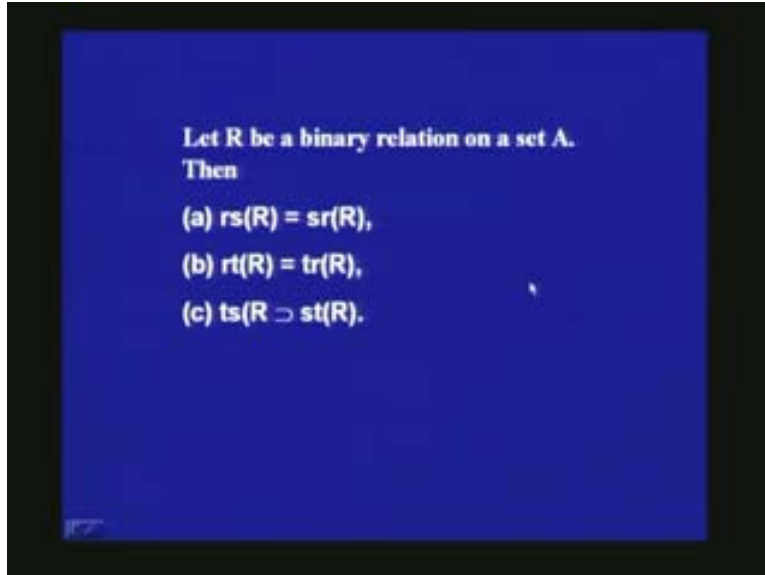

Now, let us consider some properties connecting the relation that is what the symmetric closure is, what the transitive closure is and how they are related and so on. If  $R$  is reflexive then  $s R$  and  $t(R)$  are reflexive.

(Refer Slide Time: 31:57)

If  $R$  is symmetric then  $r(R)$  and  $t(R)$  are symmetric and if  $R$  is transitive then  $r(R)$  is transitive. Now let us see, these are very simple and straight forward. Let us consider the first statement alone:  $R$  is reflexive then  $s(R)$  and  $t(R)$  are reflexive.  $R$  is reflexive would mean  $R$  is represented by a graph like this some directed arcs, if it is reflexive you will have self loops at every node. Now, to get the symmetric closure whenever there is an arc in one direction you will add the arc in other direction. This is not going to affect the self loops in anyway those self loops which are originally there are going to be there still. So, if you considered the symmetric closure that will still be reflexive. And similarly, consider the transitive closure of  $R$ , the transitive closure of  $R$  when you have a path between two nodes you will be adding an edge between the two nodes. And these self loops which are originally present are going to be still there and are not going to be affected and so the transitive closure will also be reflexive. So similarly we can prove the other two parts b and c;  $R$  is transitive then  $r(R)$  is transitive.

(Refer Slide Time: 33:40)

Now let us consider these relationships. Let  $R$  be a binary relation on a set  $A$  then  $rs(R)$  is equal to  $sr(R)$ ,  $rt(R)$  is equal to  $tr(R)$  and  $ts(R)$  contains  $st(R)$ , how do you prove that? Let us take one by one,  $rs(R)$  is equal to  $sr(R)$ . What is this and what is this? Take  $R$  first find the symmetric closure then find the reflexive closure. **I will write like this so that it is clear:** first find the symmetric closure and then find the reflexive closure. Here first find the reflexive closure then find the symmetric closure. They are all equal, either way you can do, first find the reflexive closure then find the symmetric closure or find the symmetric and the reflexive either way you can do it. So what is  $r$ ? I write  $r$  like this:  $rs(R)$  is equal to reflexive closure of what is  $s(R)$ ?  $s(R)$  is  $R$  union  $R$  power  $c$  and that is equal to reflexive closure of a relation is  $R$  union  $R$  power  $c$  union  $E$ . You are adding the equality relation.

Now what can you show about the symmetric reflexive closure of  $R$ ?  $sr(R)$  is equal to it is a symmetric closure of what  $r$  is,  $R$  that is  $R$  union  $E$ . And what is this? This is equal to  $R$  union  $E$  union  $R$  union  $E$  power  $c$  that is equal to  $R$  union  $E$  union  $R$  power  $c$  union  $E$  power  $c$ . equality relation is just the set of pairs of the form  $x x$ , as a graph if you look at it is just consisting of self loops at every node. So  $E$  power  $c$  is the same as  $E$  so you need have to not write it twice so this becomes  $R$  union  $E$  is equal to  $R$  power  $c$  and of course because of commutativity you can write it as  $R$  power  $c$  union  $E$ . So you find that this and this are equal so you get reflexive closure of the symmetric closure of a relation is the same as the symmetric closure of reflexive closure of that relation, that is the first part.

(Refer Slide Time: 36:59)

$$\begin{aligned}
 r(R) &= r(R) \\
 r(R) &= r(RUR^c) \\
 &= RUR^c \cup E \\
 r(R) &= r(RUE) \\
 &= (RUE) \cup (RUE)^c \\
 &= RUEUR^cUE^c \\
 E^c &= E \\
 &= RUEUR^c \\
 &= RUR^cUE
 \end{aligned}$$

Look at the second part; you want to show that the reflexive transitive closure of a relation  $R$  is same as the transitive reflexive closure of  $R$ , that is, what we want to prove is this  $rt(R)$  is equal to  $tr(R)$ , now what is  $rt(R)$ ?  $rt(R)$  is  $r$  of  $t(R)$  and we know that  $t(R)$  of  $R$ , that is the transitive closure is  $R$  union  $R$  squared union  $R$  cubed union etc. And the reflexive closure of that is  $E$  union  $R$  union  $R$  squared union  $R$  cubed etc where  $E$  is the equality relation. Now we want to show that this is the same as this that is the transitive reflexive closure of  $R$  is the same as this. But before going into that let us make some observations,  $E$  power  $i$  is the same as  $E$  for any  $i$  where  $i$  is an integer, what does that mean? If you take the equality relation that consists of just self loops and if you take any power of that that will be the same as the original equality relation. So  $E$  power  $i$  is the same as  $E$  for all  $i$ .

$RE$  is the same as  $ER$  is the same as  $R$ , what does that mean?

Suppose  $E$  is the relation consisting of self loops equality relation, suppose it is on some set  $a b c d$  and another relation is there on  $a b c d$  represented by  $R$  so this will have some arcs. Now, what is the concatenation of this and this, what is the composition of this and this?  $ER$ , first this and then this, that will mean  $c$  to  $c$  if you have  $c$  to  $c$  of course let me say it is like this,  $c$  to  $c$  then here you have  $c$  to  $d$  so in the composition relation you have an arc from  $c$  to  $d$ . Similarly,  $b$  to  $b$  you have and then here you have  $b$  to  $c$  and when you combine the relation the concatenation of the relation you will have  $b$  to  $c$  so  $E$  cross  $R$  is the same as  $R$ .

Similarly, if you look at  $RE$  an arc in  $RE$  will consist of a pair  $bc$  and then  $cc$  here. That will essentially compose of only  $bc$ . So an arc from here to here then a self loop followed by a self loop combine them together that it will just an arc  $b$  to  $c$ . Similarly, an arc from  $c$  to  $d$  combining with the self loop here will give you only the arc from  $c$  to  $d$ . So  $R$  cross  $E$  also will give you only  $R$ ,  $E$  cross  $R$  also will give you only  $R$ . And we also know that  $E$  power  $i$  is equal to  $E$  for all  $i$ . Making use of this you will realize that  $t$  of  $r$  of  $R$  will be

t of what is the reflexive closure? It is  $R \cup E$ , so  $t(R)$  of  $R$  of that will be  $R \cup E \cup R \cup E$  squared  $\cup R \cup E$  cubed and so on. And we know that  $E^i$  is  $E$  for all  $E$  and then  $RE$  is equal to  $ER$  and so on and  $E^i$  is the same as the  $E$ ,  $RE$  is the same as  $ER$ . So making use of these results this will essentially reduce to  $E \cup R \cup R^2 \cup \dots$ . And this we have seen earlier, it is nothing but  $rt(R)$ . So we see that  $tr(R)$  is the same as  $rt(R)$ .

(Refer Slide Time: 41:44)

$$\begin{aligned}
 tr(R) &= E \cup (R \cup E) \\
 &= (R \cup E) \cup (R \cup E)^2 \cup (R \cup E)^3 \dots \\
 &\left( \begin{array}{l} RE = ER \quad E^i = E \\ \rightarrow E \cup R \cup R^2 \cup \dots \\ = rt(R) \end{array} \right.
 \end{aligned}$$

(Refer Slide Time: 42:00)

Let  $R$  be a binary relation on a set  $A$ .  
Then

- (a)  $rs(R) = sr(R)$ ,
- (b)  $rt(R) = tr(R)$ ,
- (c)  $ts(R) \supset st(R)$ .

Let us come to the third portion, the third portion is not an equal portion it is contained  $ts(R)$  contains  $st(R)$  how do you prove that? We want to show that  $ts(R)$  contains  $st(R)$ ,

now this can be proved in this manner; take the symmetric closure of a relation  $R$ ,  $s(R)$  will always contain  $R$  by definition  $s(R)$  contains  $R$ . Now, take the transitive closure on both sides so  $ts(R)$  will contain  $t(R)$ . Now on both sides take the symmetric closure so  $sts(R)$  contains  $st(R)$ . But  $ts(R)$  is already symmetric it is a symmetric relation because first of all we are taking the symmetric relation and then taking the transitive closure. That symmetric property will not be affected by that, that we have seen earlier. So this is a symmetric relation and taking the symmetric closure of that does not make any difference you get the original relation itself and because this is symmetric these two are the same and because these two are the same you can write it as this:  $ts(R)$  contains  $st(R)$ .

(Refer Slide Time: 43:41min)

The chalkboard contains the following handwritten mathematical derivation:

$$\begin{aligned}
 ts(R) &= t(R \cup E) \\
 &= (R \cup E) \cup (R \cup E)^2 \cup (R \cup E)^3 \dots \\
 &\left[ \begin{array}{l} RE = ER \quad E^i = E \\ \rightarrow \\ = E \cup R \cup R^2 \cup \dots \end{array} \right. \\
 &= st(R) \\
 ts(R) &\supseteq st(R) \\
 s(R) &\supseteq R \\
 t(s(R)) &\supseteq t(R) \\
 sts(R) &\supseteq st(R) \\
 ts(R) &\supseteq st(R)
 \end{aligned}$$

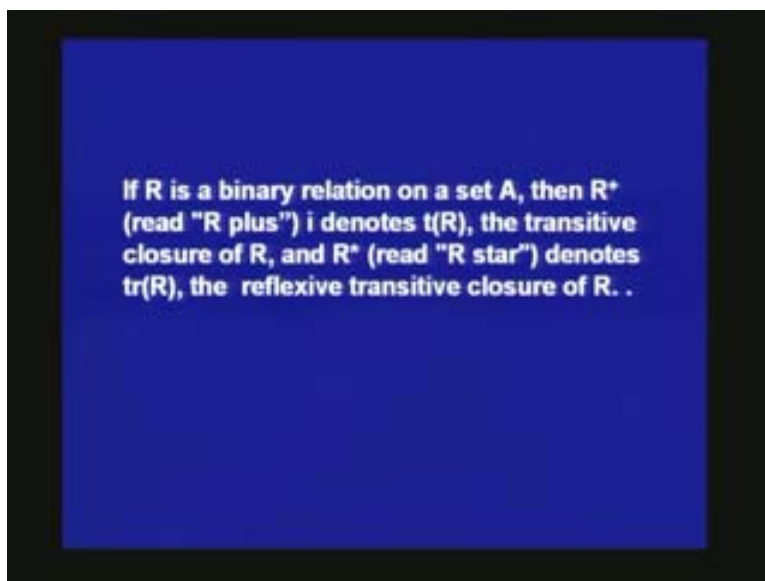

So, we prove the third part and the first two parts was equality and the third part is contained in. Let us show why it is contained in. Take the less than relation, what is  $ts$  of less than relation and what is  $st$  of less than relation. Look at this first, less than is a transitive relation so  $t$  of less than is the less than relation only and the symmetric transitive closure of that is the symmetric closure of the less than relation which is the not equal to relation. This is the less than relation on the set of non negative integers.

(Refer Slide Time: 45:02)

So  $s_t$  of less than is the not equal to relation whereas if you say  $t_s$  less than what is the symmetric closure of less than relation? That is a not equal to relation. And what is the transitive closure of this? That is the transitive closure of the not equal to relation which is the universal relation, universal relation on the set of non negative integers, they are not the same, self loops are absent here self loops are present here. So, that shows that they are not equal but  $t_s$  less than this will contain this so  $t_s$  less than contains  $s_t$  less than. So it is the containment in this case not the equality. There are examples to show that they cannot be equal.

(Refer Slide Time: 45:41)

Now, generally you say that if  $R$  is a binary relation on a set  $A$ , then  $R^+$  which denotes the transitive closure. Transitive closure is usually denoted by  $R^+$ . Instead of  $t(R)$  many times you use the notation  $R^+$  that is the transitive closure.  $R^*$  to the power star is read as  $R$  to the power star that denotes the reflexive transitive closure of the relation  $R$ . And  $rt(R)$  is  $tr(R)$  that we have seen, so instead of saying that you use  $R$  to the power star. These transitive closure relations are really very useful in many cases.

We will consider one or two applications. One is, consider a set of procedures, you have a set of procedures  $P_1, P_2, P_3$  etc, then you represent like this;  $P_i R P_j$  if  $P_i$  calls  $P_j$ . If  $P_i$  calls this  $P_j$  as a sub routine then you say  $P_i$  or  $P_j$  then what does  $P_i R^+ P_k$  represent, what does it represent? See  $P_i$  may call  $P_j$  and  $P_j$  may call  $P_k$ ,  $P_i R$  may call  $P_k$  and if you say  $P_i R^+ P_k$  the set of such  $P_k$ s are the set of procedures which will be called when  $P_i$  is executed. When the procedure  $P_i$  is executed you will get  $P_i R^+ P_k$  that means  $P_k$  will be invoked during the execution of  $P_i$ .

And what does  $P_i R^*$  to the power star  $P_i$  represent?

Of course because this will represent the reflexive transitive closure so it will also include  $P_i$ . Here this may not include  $P_i$  this is the set of procedures which will be active at some point when  $P_i$  is invoked. When  $P_i$  is called the set of procedures will be active at some point of time is denoted like this. Now, when do you say that  $P_i R^*$  to the power star  $P_i$  because reflexive closure will always contain  $P_i$  so this will always hold. But if you say  $P_i R^+ P_i$  what does that mean? It means that during the execution of  $P_i$  it invokes itself either directly or indirectly.  $P_i$  may call itself or  $P_i$  may call  $P_j$  or  $P_j$  may call  $P_i$  whatever it is in that case  $P_i$  is recursive, it is a recursive program directly or indirectly so this is one application.

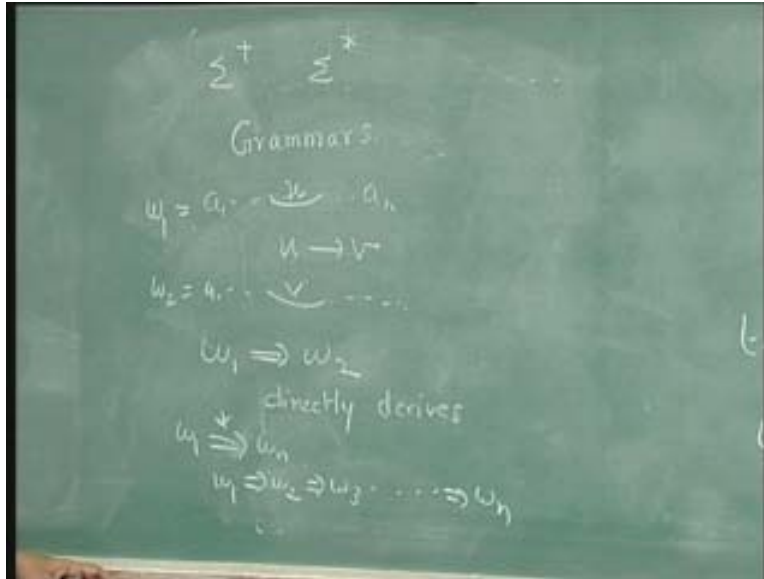

(Refer Slide Time: 49: 32)

Usually this sort of notations is also used in grammars. This star and plus we already seen when we defined sigma plus and sigma power star. So in grammars again this notation is

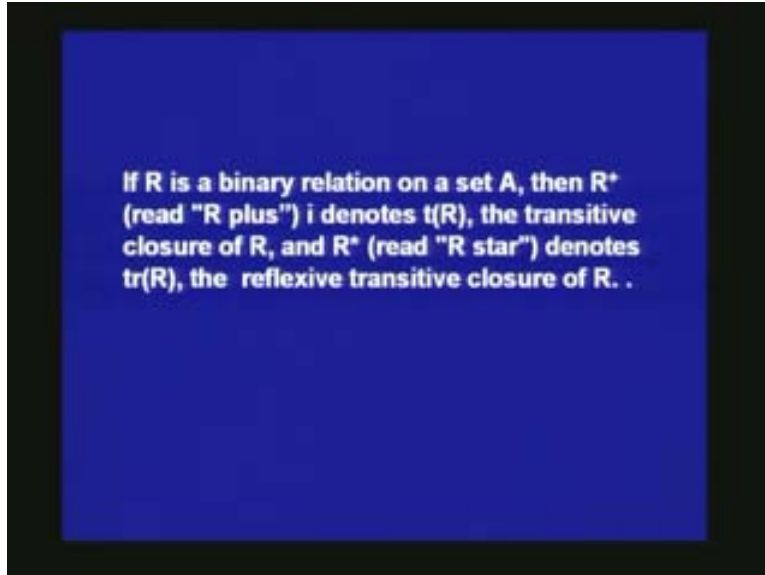

used. suppose you have a string say some  $a_1, a_2$  and an and some portion of it is I will denoted by  $u$  is replaced by a roll  $u$  goes to  $v$ , so from this string you get this, if I write as  $w_1$  it is a string over some alphabet and if a portion of it is replaced by  $v$ , this  $u$  is replaced by  $v$  but the rest of the strings will be there then you get  $w_2$  it is usually denoted by  $w_1$  derives  $w_2$  this represents a relation between strings and this is called directly derives, this is if  $w_1$  derives  $w_n$  by this step that is represented by this notation which is know as the reflexive transitive closure.

(Refer Slide Time: 51:34)

So if  $w_1$  is derived in one step you call it as directly derives. But if you have  $w_1$  deriving  $w_2$  then  $w_2$  deriving  $w_3$  in one step and so on until you get some  $w_n$ . Each is obtained from the previous one by the application of a single rule. And this you write as  $w_1$  to the power star  $w_n$  that is this star you call it as derives. Or in other words if you get  $w_2$  from  $w_1$  in one step you write  $w_1$  derives  $w_2$ .

(Refer Slide Time: 52:25)

If you get  $w_2$  from  $w_1$  in several steps and  $w_n$  from  $w_1$  in several steps you write it as  $w_1 \Rightarrow w_n$ . This denotes derives. This denotes derives, this also represents a relationship between the strings, this also denotes the relationship between the strings and generally we have  $w_i \Rightarrow w_i$  because each string is derived from itself, that is what we have. So generally we can easily see that this is the reflexive transitive closure of  $\Rightarrow$ .

Therefore, to find out the communication paths in a communication network all the pair of nodes which can be connected or from one node where you can send a message to any other node you have to calculate the transitive closure. And here again like in grammar you have this derivation. Even in automaton which is a corresponding acceptance device for a grammar you have these relationships and you may be making use of this in several subjects in computers science and transitive closure is a very important concept. That is why people have spent time in finding efficient ways of finding the transitive closure as we have already seen if you represent the relation by the adjacency matrix then if you calculate the transitive closure in naive manner then you may require order  $n^4$  time because the adjacency matrix will be represented by as  $n$  by  $n$  Boolean matrix and you have to calculate  $A$ ,  $A^2$ ,  $A^3$  up to a power  $n$  and find the sum.

But there are other efficient methods like Warshall's algorithm and Warren's algorithm where you need not go through all those steps it takes only order  $n^3$ . So we have considered some closure properties of relations like reflexive, transitive and symmetric closure. There are other aspects of relations like partial order, linear order, well order, a lexicographic order on string and so on, they are also very useful in certain things. Then there is an equivalence relation which is also a very important concept. We shall consider about partially ordered sets and partial orders and also equivalence relations in the coming lectures.
