**Equivalence Relations and Partitions**

We have been considering about equivalence relation. An equivalence relation is a binary relation which is reflexive, symmetric and transitive. A binary relation  $R$  on a set  $A$  if it satisfies these three conditions it is called an equivalence relation. And we have seen some examples of equivalence relation.

One is the mod  $k$  set of integers, take the set of integers and the relation mod  $k$ . That is two integers  $a$  and  $b$  are related if  $a$  minus  $b$  is equal to some  $n$  times  $k$  or  $a$  and  $b$  leave the same remainder when divided by the integer  $k$ . This is called mod  $k$  relation and we have seen that it is an equivalence relation because it satisfies the three properties reflexive, symmetric and transitive. And it divides the set of integers into  $k$  equivalence classes.

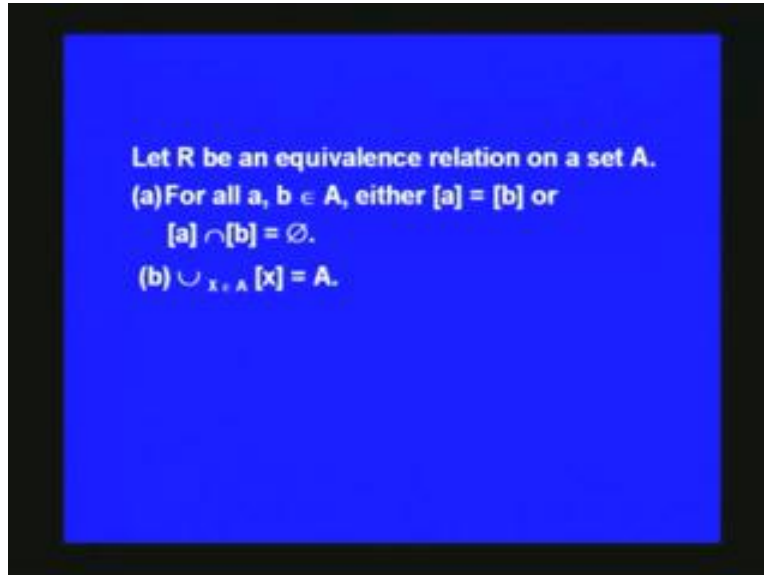

(Refer Slide Time: 03.04min)

The set  $S_0$  is integers leaving remainder 0 when divided by  $k$ .  $S_1$  is the integers leaving remainder 1 when divided by  $k$ ,  $S_2$  is the set of integers leaving remainder 2 when divided by  $k$  and  $S_{k \text{ minus } 1}$  is the set of integers leaving remainder  $k$  minus 1 when divided by  $k$ . And we find that if you take any two of them they are disjoint, there is no element which is present in both of them. These are called classes of the equivalence relation and we find that here there are  $k$  equivalence classes  $S_0 S_1$  up to  $S_{k \text{ minus } 1}$ . And each class is separate from the other that is the classes are all disjoint. And the union of them will

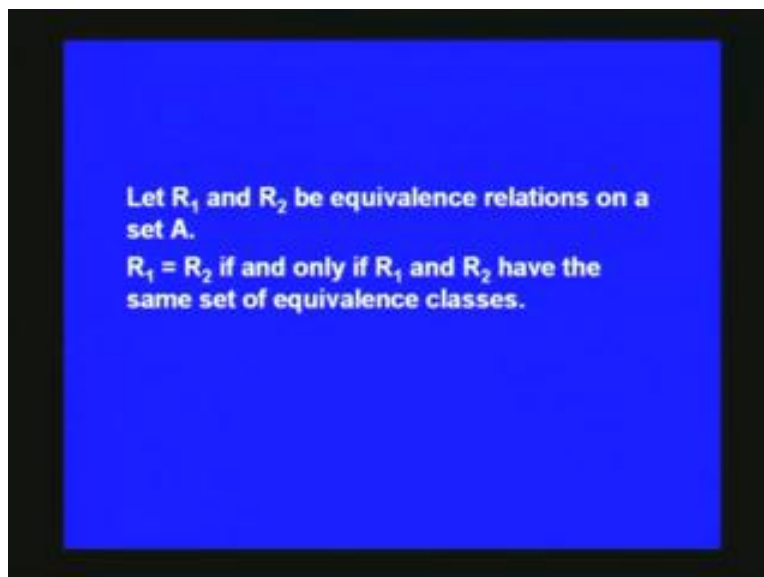

make the whole set I, the union of all these equivalence classes will make the whole set I and that is what we learnt in this theorem.

(Refer Slide Time: 03.46min)

Let  $R$  be an equivalence relation on a set  $A$  then for all  $a, b$  belonging to  $A$  either the equivalence class of  $a$  is the same as the equivalence class of  $b$  or equivalence class of  $a$  and equivalence class of  $b$  are disjoint that is what we meant by equivalence class of  $a$  intersection equivalence class of  $b$  is phi, they are disjoint. And the union of all such equivalence classes makes the whole set  $A$  that is given by the second part. From this we immediately get this result.

(Refer Slide Time: 04.16min)

Let  $R_1$  and  $R_2$  be equivalence relations on a set  $A$  then  $R_1$  is equal to  $R_2$  if and only if  $R_1$  and  $R_2$  have the same set of equivalence classes. Suppose I have a set  $A$  consisting of  $a, b, c, d, e, f$  then I have an equivalence relation on this, equivalence relation you know that is represented by a complete digraph so suppose I have this  $c, d, e, f$  I have this equivalence relation  $R_1$  on a represented like this. This divides  $a$  into equivalence classes  $a$  and  $b$  be in one equivalence class,  $c$  and  $d$  in one equivalence class and  $e$  and  $f$  in another equivalence class.

Suppose I define another equivalence relation  $R_2$  if it divides  $a, b, c, d, e, f$  into different equivalence classes this is a different equivalence. Suppose I have  $a, b, c$  in one class and  $d, e$  in one class and  $f$  in one class if I draw the diagram there will be a complete digraph with  $a, b, c$  there will be a complete digraph with  $d$  and  $e$  and there will be a complete digraph with  $f$ , they are different this is not the same as this.

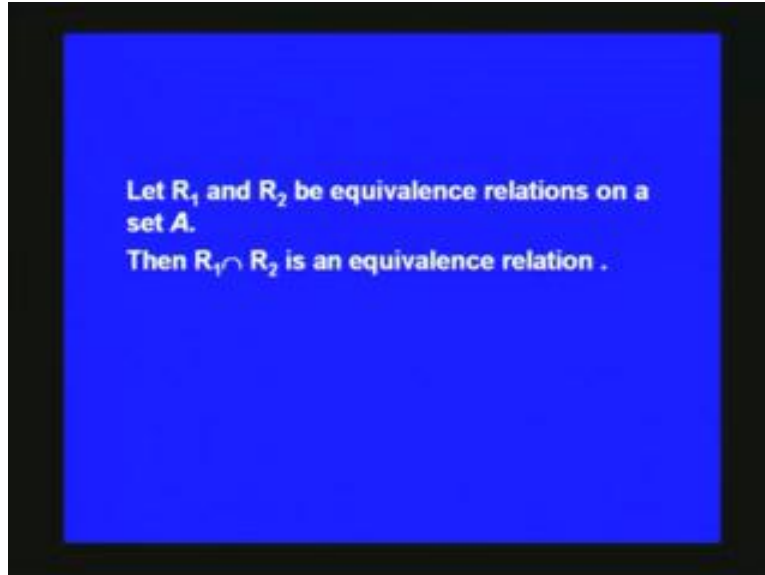

(Refer Slide Time: 05.58min)

When will  $R_2$  be equal to  $R_1$ ?

Only when you have the same diagram for  $R_2$  also only then the relations are the same. And in that case  $a$  and  $b$  will be in one equivalence class,  $c$  and  $d$  will be in one equivalence class,  $e$  and  $f$  will be in one equivalence class. So  $R_1$  and  $R_2$  divide  $A$  into the same equivalence classes.  $R_2$  also will give the same equivalence classes. Only in that case you can say that  $R_1$  and  $R_2$  are equivalent so that is what is meant by this slide.  $R_1$  is equal to  $R_2$  if and only if  $R_1$  and  $R_2$  have the same set of equivalence classes. I have explained this as an example, this is true for any set and any equivalence relations  $R_1$  and  $R_2$  on  $A$ .

(Refer Slide Time: 06.52min)

Now, what do you mean by the intersection of equivalence relations  $R_1$  and  $R_2$ ?

We know that a relation is essentially a set. It is a set of ordered pairs; a binary relation is a set of ordered pairs defined on a set  $A$  cross  $A$ . So you define  $R_1$  and you define  $R_2$  as a set of intersection you can define  $R_1$  intersection  $R_2$ . So  $R_1$  is an equivalence relation on  $A$ ,  $R_2$  is an equivalence relation on  $A$  and what can you say about  $R_1$  intersection  $R_2$ ? This is also an equivalence relation on  $A$ . Let us take an example, the previous one, this is  $R_1$  the set  $A$  is  $a, b, c, d, e, f$  and the set consists of six elements  $a, b, c, d, e, f$  and  $R_1$  is an equivalence relation defined like this.

Let  $R_2$  be defined like this  $a, b, c, d$  then  $e, f$ , so how many equivalence classes you have here? You have  $a$  in one equivalence class,  $b$  and  $c$  in one equivalence class,  $d$  in one equivalence class,  $e$  and  $f$  in one equivalence class.

Now what can you say about  $R_1$  intersection  $R_2$ ?

It will have all the arcs which are present both in  $R_1$  and  $R_2$ . So you will find that  $e, f$  these arcs are present in both so they are present in the intersection but the self loops are present in both the relation  $R_1$  and  $R_2$  so they are present here. But the arcs between  $a$  and  $b$  are present in  $R_1$  but they are not present in  $R_2$  so it will not be present in the intersection. Similarly, the arcs between  $c$  and  $d$  are the ordered pairs  $cddc$  they are present in  $R_1$  but they are not present in  $R_2$  so they will not be present in the intersection. Similarly,  $bccb$  the ordered pairs  $bccb$  are present in  $R_2$  but not in  $R_1$  so they will not be present here.

Now look at this relation, is this an equivalence relation? This is an equivalence relation because it is reflexive, it is symmetric and it is transitive.

(Refer Slide Time: 10.18min)

So how can you say that it is reflexive, it is symmetric and it is transitive?

Now take  $R_1$  and  $R_2$  both will have the self loops because  $R_1$  is reflexive both are equivalence relation. Please remember that  $R_1$  and  $R_2$  are equivalence relation on the set  $A$ . So both are reflexive and the self loops will be present in both the things so in the intersection also they will be present therefore the reflexive property is okay.

What about symmetry property?

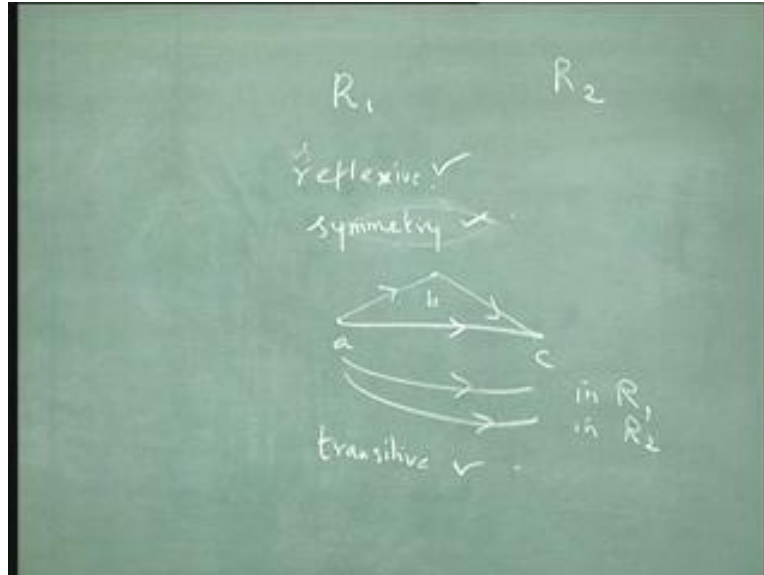

If you have an arc in one direction you should also have an arc in the other direction. If such a thing is present in  $R_1$  and such a thing is present in  $R_2$  it will be present in  $R_1$  one intersection  $R_2$  two also. For example here between  $e$  and  $f$  such an arc is present a pair of arcs are present that will be present in the intersection also. But if it is present in  $R_1$  and if it is not present in  $R_2$  or if it is present in  $R_2$  and not present in  $R_1$  then it will not be present in the intersection.

Symmetric means between any two pair of nodes either there should be no arcs or if you have one arc in one direction you should also have an arc in the other direction. So that condition will also be satisfied. So symmetry property is also satisfied.

What about transitivity?

Now, if you have  $a, b$  and  $b, c$  in  $R_1$  and in  $R_2$  also, so if you have  $a, b$  and  $b, c$  in  $R_1$  and you also have  $a, b$  and  $b, c$  in  $R_2$  then it will be present in  $R_1$  intersection  $R_2$ . But  $R_1$  is an equivalence relation so it is transitive, so  $a, c$  will be present in  $R_1$ . Similarly because  $a, b$  and  $b, c$  are present in  $R_2$  and  $R_2$  is transitive this will be present in  $R_2$  also. So such an arc will be present in  $R_1$  intersection  $R_2$  so the transitive property is also satisfied.

(Refer Slide Time: 12.54min)

Since all these properties are satisfied  $R_1 \cap R_2$  is an equivalence relation. So this is an equivalence relation.

For example, we have considered  $R_1$  like this then  $R_2$  like this on the set  $A$  having six elements.  $R_1 \cap R_2$  consists of these elements, the equivalence classes here are  $a$  will be in one equivalence class,  $b$  alone will be in one equivalence class,  $c$  alone will be in one equivalence class,  $d$  will be in one equivalence class,  $e$  and  $f$  will be in one equivalence class. These are the equivalence classes corresponding to  $R_1 \cap R_2$ . But we cannot say like this for the union.

Suppose  $R_1$  is an equivalence relation and  $R_2$  is an equivalence relation can you say  $R_1 \cup R_2$  is an equivalence relation? We cannot say that,  $R_1 \cup R_2$  need not be an equivalence relation. And  $R_1$  an equivalence relation on  $a, b, c, d$  defined like this,  $a, b, c, d$  by the diagraph like this. Here  $a, b$  are in one equivalence class and  $c, d$  are in one equivalence class. Let  $R_2$  be an equivalence relation defined like this. Here,  $a$  is one equivalence class,  $b$  and  $c$  are in one equivalence class,  $d$  is in one equivalence class.

Now what can you say about  $R_1 \cup R_2$ ?

$R_1 \cup R_2$  will have all the arcs present in this or this. It will have self loops at all nodes, it will have this because it is in  $R_1$ , it will have this because it is in  $R_2$ , it will have this because it is in  $R_1$  this is  $R_1 \cup R_2$ . The reflexive property is not affected,  $R_1 \cup R_2$  will be still reflexive. The symmetric property is also not affected  $R_1 \cup R_2$  is still symmetric. But  $R_1 \cup R_2$  is not transitive, you have an arc from  $a$  to  $b$  and you have an arc from  $b$  to  $c$  but you do not have an arc from  $a$  to  $c$ . That is, you have the ordered pair  $a, b$  you also have the ordered pair  $b, c$  but you do not have the ordered pair  $a, c$  is not present. So this is not transitive so this is not an equivalence relation.

(Refer Slide Time: 16.09min)

But if you take the transitive closure of that then that will be an equivalence relation. Only the transitive property gets affected so if you take the transitive closure you will get an equivalence relation.

(Refer Slide Time: 16.39 min)

Let  $R$  be a binary relation on  $A$  and let  $R' = \text{tsr}(R)$ , the transitive symmetric reflexive closure of  $R$ . Then

- $R'$  is an equivalence relation on  $A$ , called the equivalence relation induced by  $R$ , and
- if  $R''$  is an equivalence relation and  $R'' \supset R$ , then  $R'' \supset R'$ . (Thus  $R'$  is the smallest equivalence relation which contains  $R$ )

Let  $R$  be a binary relation on a set  $A$  and first take the reflexive then the symmetric then the transitive closure of  $R$  then the resulting relation is an equivalence relation.  $R'$  is the transitive symmetric reflexive closure of  $R$ , then  $R'$  is an equivalence relation on  $A$  called the equivalence relation induced by  $R$  and  $R'$  is the smallest equivalence relation which contains  $R$ .

relation and if  $R_2$  contains  $R$  then  $R_2$  contains  $R$  dash. Thus  $R$  dash is the smallest equivalence relation which contains  $R$ .

So for example take this;

Take a set  $A$  with two elements  $a$  and  $b$  like this, this is not reflexive because you are not having an element, it is not symmetric also. Now first take the reflexive closure of that and that will be adding a self loop here, then take the symmetric closure that is you will be adding another one. Obviously it is transitive so while taking the transitive closure you do not have any problem, this will be the same as this that will give you an equivalence relation.

(Refer Slide Time: 18.43min)

So when you first take the reflexive closure the reflexive property is satisfied. And then when you take the symmetric closure you get the symmetric property but the reflexive property will not be affected by that. Then when you take the transitive closure the reflexive and the symmetric property will be retained and you also additionally get the transitive closure.

Now if you take any other relation  $R_2$  containing equivalence relation  $R_2$  dash containing  $R$  it will also contain this. Here we have taken only two elements, suppose I take some more elements, suppose I have four elements  $a, b, c, d$  and something like this  $R$  is this  $a, b, c, d$  then when I take the reflexive, symmetric and then transitive closure you get the equivalence relation  $a, b, c, d$  like this, I will add one more element  $e$  it is like this  $e$ .

Suppose I have an equivalence relation  $R$  on a set with five elements like this then when I take the transitive symmetric reflexive closure of  $R$  I get this. Consider relation  $R_2$  where you have  $a, b, e$  and  $c, d$  like this, this is an equivalence relation because it is represented by a directed graph which has got components that are complete digraphs. Here there are

three equivalence classes  $a$   $b$  is in one equivalence class,  $c$   $d$  is in one equivalence class,  $e$  is in one equivalence class. here there are two equivalence classes  $a$   $b$   $e$  are in one equivalence class,  $c$   $d$  is in one equivalence class.

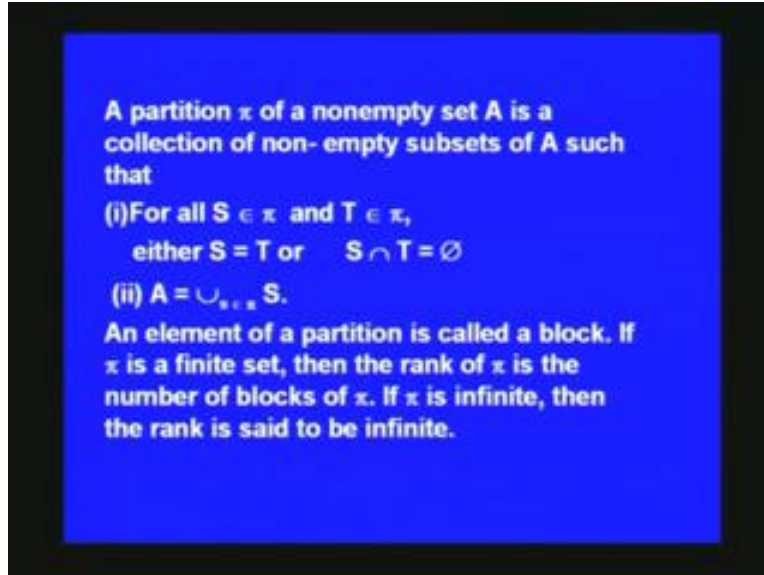

Now you can very easily see that  $R_2$  contains this, this contains this. Obviously  $R_2$  contains  $R$ ,  $R$  is present here also so  $R_2$  will contain this. If an equivalence relation contains this, it will also contain the symmetric. This is the smallest equivalence relation containing  $R$ . This is another equivalence relation which contains  $R$ . You see  $a$   $b$  is present there, the self loop is present there,  $c$   $d$  is present there so this also contains  $R$  but it is a bigger equivalence relation. It will always contain the transitive symmetric reflexive closure of  $R$  which is the smallest equivalence relation containing  $R$ , that is what this result says.

(Refer Slide Time: 22.33min)

Now we shall see the correspondence between partitions and equivalence relation.

(Refer Slide Time: 22.36min)

What is a partition?

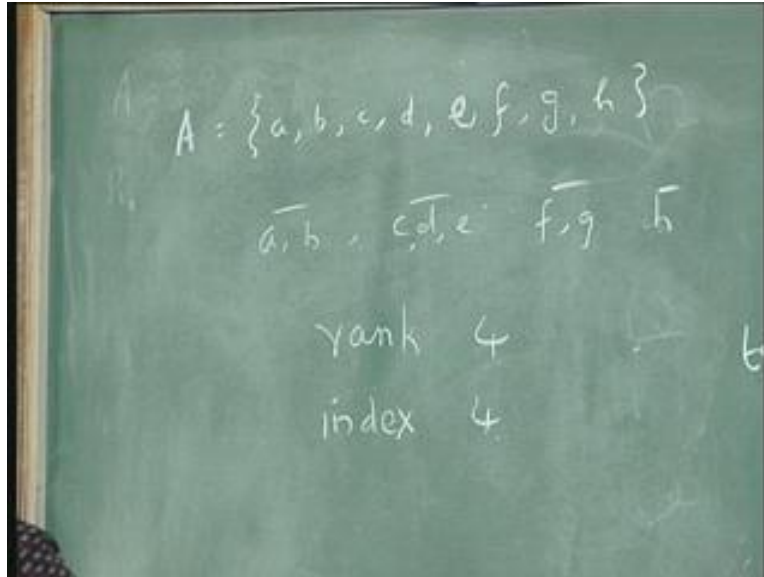

Before going into the formal definition take some examples. Let me have a set  $A$  having elements  $a, b, c, d, e, f, g, h$  then I divide the elements into blocks. Suppose I can put  $a, b$  in one block  $c, d, e$  in one block,  $f$  and  $g$  in one block,  $h$  in one block like that we can put. The eight elements are divided into four blocks. You are dividing the eight elements into blocks that is called a partition, this is a finite set.

If you take the infinite set of examples of integers you can divide them into three blocks having negative integers in one block, positive integers in one block,  $0$  in one block. So you can divide like that into three blocks. Or if you take the set of non negative integers then you can divide them into two blocks one having the even non negative integers and another having odd non negative integers. You can partition into odd and even numbers.

That is you can divide it into blocks so that one element is present in only one block and it will not be present in two blocks but every element will be present in one block. So a partition  $\pi$  of a nonempty set  $A$  is a collection of nonempty subsets of  $A$  such that for all  $S$  belonging to  $\pi$  and  $T$  belonging to  $\pi$  either  $S$  is equal to  $T$  or  $S \cap T$  is equal to  $\emptyset$ ,  $A$  is equal to union of  $S$  belongs to  $\pi$ , union of  $S$  belonging to  $\pi$   $S$  is  $A$ . That is, you are putting the elements of a set  $A$  into blocks and separate blocks are disjoint and one element will belong to one and only one block.

An element of a partition is called a block. If  $\pi$  is a finite set then the rank of  $\pi$  is the number of blocks of  $\pi$ . For example, the rank of this is number of blocks  $1, 2, 3, 4$  there are 4 blocks so the rank is 4 or the index is 4, you can use the word index also for this, here the rank is 4 which is the number of blocks, you can also say the index is 4.

(Refer Slide Time: 25.48min)

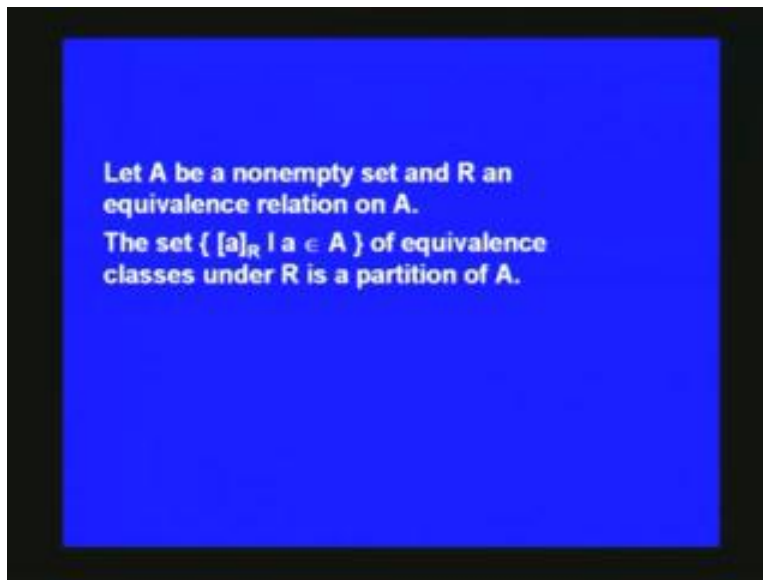

If  $\phi$  is a partition then the rank on a infinite set, for example the set of non negative integers you are dividing it into odd and even integers so the rank is 2, there are two equivalence classes or two blocks in the partition. I should say there are two blocks in the partition and so the rank is 2 but you may also have infinite number of blocks you can put every non negative integer in one block and in that case the rank will be infinite, the number of blocks will be infinite. So if you take the set of non negative integers 0, 1, 2, 3 up to this each one you can put in one block like that then the rank is infinite.

If you put all the even in one block and all the odd integers in one block you are having only two blocks then you say that the rank here is 2. But if it is a finite set obviously the rank has to be finite only.

(Refer Slide Time: 27.05min)

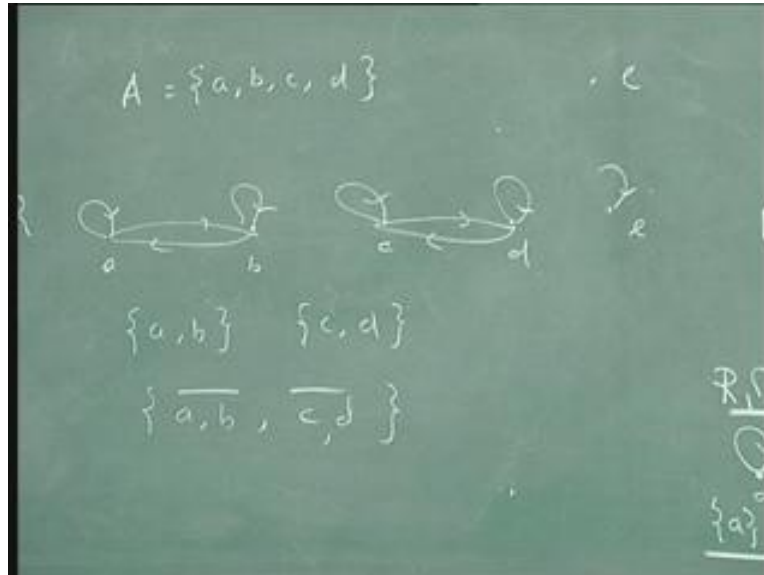

(Refer Slide Time: 27.13min)

Now, we see the correspondence between the equivalence relation and the partition. Let  $A$  be a nonempty set and  $R$  an equivalence relation on  $A$  then the collection of the equivalence classes  $a_R$   $a$  belongs to  $A$  of equivalence classes under  $R$  is a partition of  $A$ . In all these examples we have seen that, again take this example. The underlying set here is  $a, b, c, d$ , the equivalence relation  $R$  is represented like this so the equivalence classes are  $a$  and  $b$  will belong to one equivalence class,  $c$  and  $d$  will belong to one equivalence class. Actually this corresponds to the partition where  $a$  and  $b$  will be in one block and  $c$  and  $d$  will be in one block. So this equivalence relation induces a partition on  $A$ , that is this

partition a and b in one block c and d in one block. Each equivalence class will be one block. So you say that an equivalence relation induces a partition on A.

(Refer Slide Time: 28.54min)

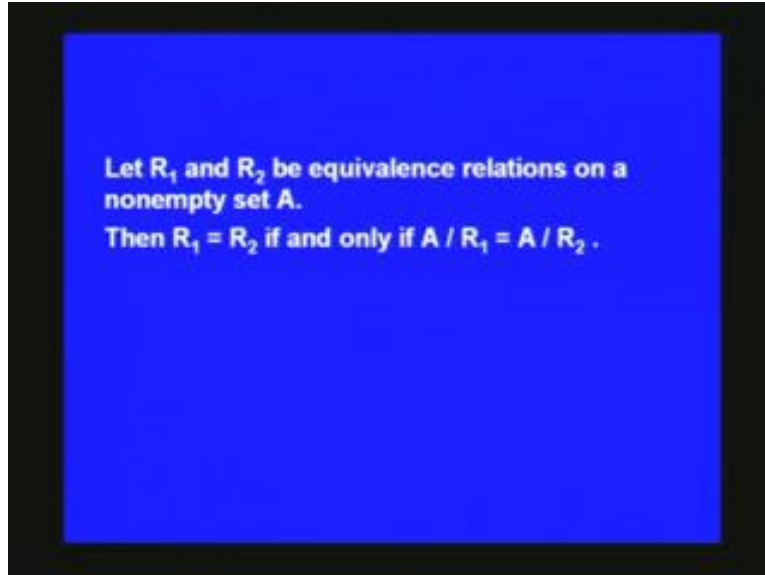

This is what we have seen.

(Refer Slide Time: 29.00min)

Let  $R$  be an equivalence relation over a nonempty set  $A$ . The quotient set,  $A / R$ , is the partition  $\{ [a]_R \mid a \in A \}$ .  
The quotient set is also called  $A$  modulo  $R$  or the partition of  $A$  induced by  $R$ .

Let  $R$  be an equivalence relation over a nonempty set  $A$ . the quotient set  $a_R$  is the partition this is called the quotient set, this is called  $A$  modulo  $R$  the partition of  $A$  induced by  $R$ .

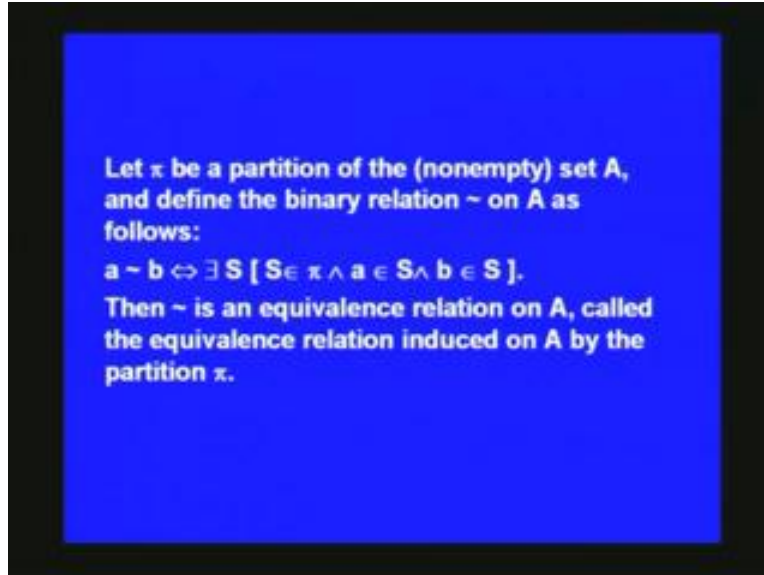

(Refer Slide Time: 29.25min)

Now, immediately you can see, let  $R_1$  and  $R_2$  be the equivalence relation on a nonempty set  $A$ . then we have seen that  $R_1$  is equal to  $R_2$  only if they have the same set of equivalence classes, we have seen this result earlier.  $R_1$  and  $R_2$  be equivalence relation on a set  $A$ .  $R_1$  is equal to  $R_2$  if and only if  $R_1$  and  $R_2$  have the same set of equivalence classes, this we have already seen. So if  $R_1$  and  $R_2$  are equivalence relation and  $R_1$  is equal to  $R_2$  they have the same set of equivalence relation so they will induce the same partition on the underlying set.

$A$  by  $R_1$  is equal to  $A$  by  $R_2$  means they will induce the same partition or the underlying set will be divided into equivalence classes in the same way in both the cases. That is the same partition is induced in both cases that is what is meant by this result.

(Refer Slide Time: 30.44min)

So we have seen that an equivalence relation induces a partition on the underlying set. Conversely you can have a partition and the partition can induce an equivalence relation on a set  $A$ , the idea is very similar.

So look at this set, you are having a set  $A$  having eight elements and there is a partition of that. there are four blocks  $a, b$  belongs to one block;  $c, d, e$  belongs to one block;  $f, g$  belongs to one block and  $h$  alone belongs to one block, this induces an equivalence relation on the set  $A$  where  $a$  and  $b$  will be equivalent so you have  $a, b$  the equivalence relation can be represented by this diagraph,  $f$  and  $g$  are equivalent so you will have like this and  $c, d, e$  are equivalent and  $h$  alone is one equivalence class. So this partition induces this equivalence relation on the set  $A$ . And formally if we define this you say  $a$  is related to  $b$  if  $a$  and  $b$  belong to the same block.

(Refer Slide Time: 32.22 min)

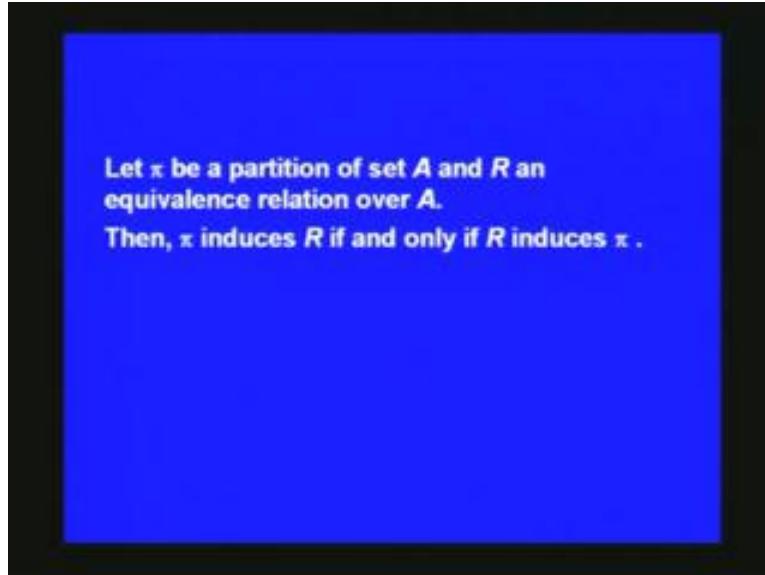

Formal notation is defined like this; let  $\pi$  be a partition of the nonempty set  $A$  and define the binary relation equivalent which is this relation on  $A$  as follows,  $a$  is related to  $b$  is equivalent to saying that there is a block  $S$  such that  $S$  is a block of  $\pi$  and  $a$  and  $b$  belong to the same block. This is an equivalence relation because reflexive property will be satisfied  $a$  will be related to  $a$  because it is in the same block.

And if  $a$  and  $b$  are in the same block  $b$  and  $a$  in the same block so symmetric property will be satisfied. When you say  $a$  and  $b$  are in the same block  $b$  and  $a$  are in the same block. Then transitive property is also satisfied because if  $a$  and  $b$  are in one block and  $b$  and  $c$  are in one block that is  $a, b, c$  all of them will be in the same block so that  $a$  and  $c$  will be in the same block. So the transitive property is also satisfied.

So since this relation satisfies all the three properties reflexive, symmetric and transitive you find that this is an equivalence relation. And you call this equivalence relation as a equivalence relation induced on  $A$  by the partition  $\pi$ . So this is called an equivalence relation on  $A$  called the equivalence relation induced on  $A$  by the partition  $\pi$ . So we see that an equivalence relation induces a partition on the set  $A$  and a partition on the set  $A$  induces an equivalence relation on  $A$ . Let  $\pi$  be a partition of a set  $A$  and  $R$  an equivalence relation over  $A$ . Then  $\pi$  induces  $R$  if and only if  $R$  induces  $\pi$ , obviously that is true.

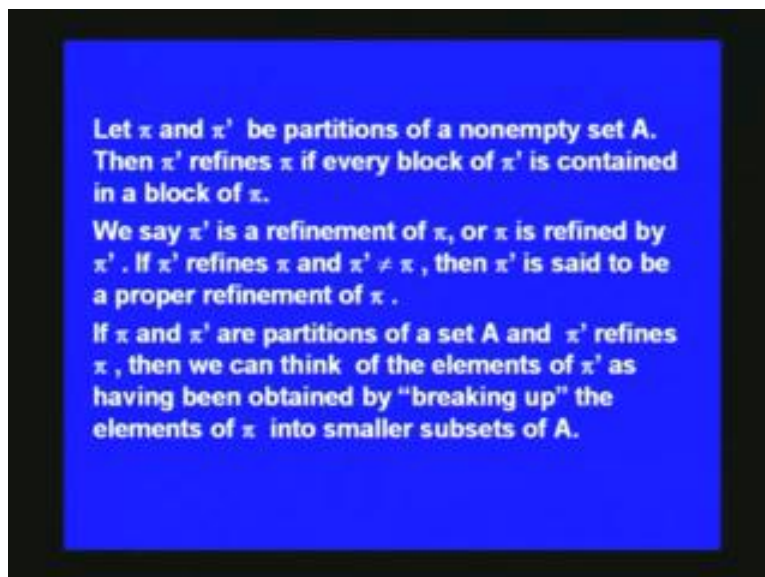

(Refer Slide Time: 34.38min)

Look at this, this is the set  $A$  this is a partition  $\pi$  and this is the equivalence relation  $R$ .  $\pi$  induces this equivalence relation  $R$  and you can see that  $R$  induces this partition  $\pi$  on  $A$  so  $\pi$  induces  $R$  if and only if  $R$  induces  $\pi$ . This is the correspondence between equivalence relations and partitions.

Next we shall see what is meant by a refinement of a partition and also what is meant by product of two partitions and sum of two partitions.

(Refer Slide Time: 35.32min)

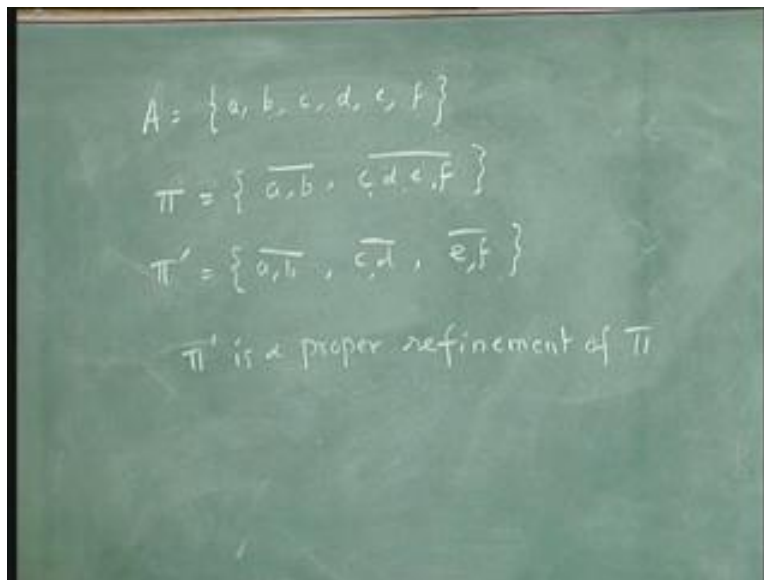

Let  $\pi$  and  $\pi'$  be partitions on a nonempty set  $A$  then  $\pi'$  refines  $\pi$ . If every block of  $\pi'$  is contained in a block of  $\pi$  we say  $\pi'$  is a refinement of  $\pi$  or  $\pi$  is refined by  $\pi'$ . If  $\pi'$  refines  $\pi$  and  $\pi'$  is not equal to  $\pi$  then  $\pi'$  is said to be a proper refinement of  $\pi$ .

Let us see what is meant by that. Take an example,  $A$  is the set say  $a, b, c, d, e, f$  then  $\pi$  is a partition on  $A$  where  $a, b$  are in one block  $c, d, e, f$  are in one block.  $\pi'$  is another partition where  $a, b$  is in one block  $c, d$  is in one block  $e, f$  is in one block.

Now look at  $\pi$  and  $\pi'$ . There are three blocks here there are two blocks here. Every block of  $\pi'$  is contained in a block of  $\pi$   $a, b$ , this is contained here this is contained here this is also contained here. If this condition is satisfied you say that  $\pi'$  is a refinement of  $\pi$  or  $\pi$  is refined by  $\pi'$ , that is, in a sense what is meant by  $\pi$  and  $\pi'$ ?

$\pi$  and  $\pi'$  are partitions of  $A$  and  $\pi'$  refines  $\pi$  then we can think of the elements of  $\pi'$  as having been obtained by breaking up the elements of  $\pi$  into smaller subsets of  $A$ . So here this is broken up into smaller elements so you are dividing into two parts so you are breaking it up. So this is called the refinement of all and  $\pi$  is said to be refined by  $\pi'$ . Of course  $\pi$  is its own refinement if they are not equal one is called the proper refinement of the other,  $\pi'$  is a proper refinement of  $\pi$ .

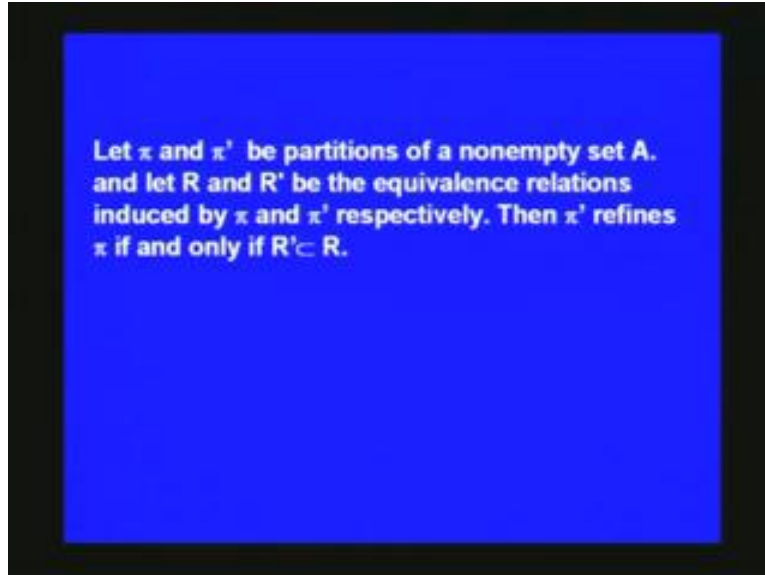

(Refer Slide Time: 38.24min)

Now, obviously a partition induces an equivalence relation. So  $\pi$  will induce an equivalence relation on  $A$ ,  $\pi'$  will also induce an equivalence relation on  $A$ . What is the connection between these two equivalence relations?

Let us see that.

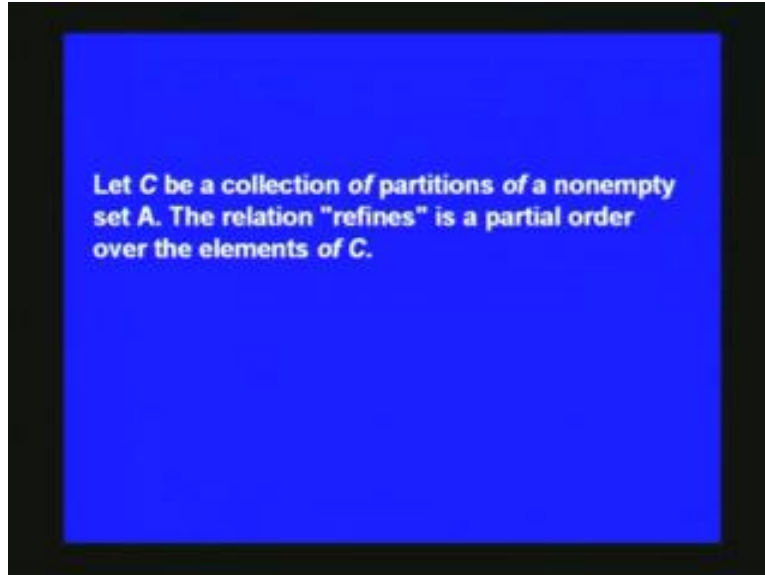

(Refer Slide Time: 38.52min)

Let  $\pi$  and  $\pi'$  be partitions of a nonempty set  $A$ . And let  $R$  and  $R'$  be the equivalence relations induced by  $\pi$  and  $\pi'$  respectively. Then  $\pi'$  refines  $\pi$  if and only if  $R'$  is contained in  $R$ . Obviously see here,  $\pi$  induces an equivalence relation where  $a, b$  are connected by, it is a complete diagraph and  $c, d, e, f$  are connected in all possible manners whereas  $\pi'$  you will have  $a, b$  like this but this is  $R'$ ,  $R$  is induced by  $\pi$  so  $c, d, e, f$  and all pairs of arcs are present. This is the equivalence relation represented by a diagraph  $R$  which is induced by  $\pi$ .

Now  $\pi'$  also induces an equivalence relation. It will not have all these pairs but it will have these elements,  $\pi'$  induces  $R'$  which will have these elements. Obviously whatever is present in  $R'$  is present in  $R$  also so  $R'$  will be contained in  $R$ . So you can very easily see that  $\pi'$  refines  $\pi$  if and only if  $R'$  is contained in  $R$ .

(Refer Slide Time: 41.14min)

Let  $C$  be a collection of the partitions of a nonempty set  $A$ , then the relation refines is a partial order over the elements of the set  $C$ . Again I will take just three elements in a set  $A$  and let us see what the partitions are.

Take a set  $A$  having three elements  $a, b, c$ , what are the partitions?  $\pi_1$  is a partition having all the three elements,  $\pi_2$  is a partition having each one in a separate block,  $\pi_3$  will be a partition having  $a$  and  $b$  in one block and  $c$  in a separate block,  $\pi_4$  will be  $a$  in one block  $b$  and  $c$  in one block,  $\pi_5$  will be  $a$  and  $c$  in one block  $b$  in one block.

Now which one refines this?

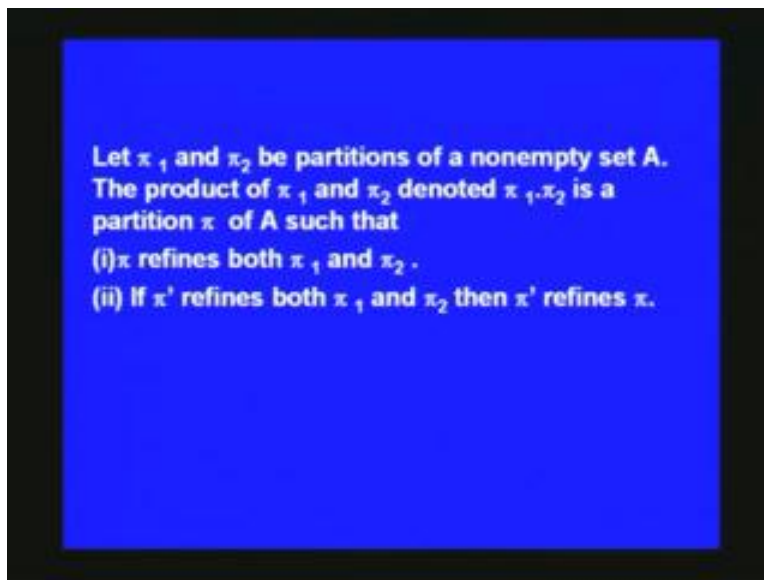

$\pi_2$  will refine this, this, this and this  $\pi_2$  will refine every one of that and  $\pi_3$  will refine this,  $\pi_4$  will refine this,  $\pi_5$  will refine this, this is breaking this like this. But none of  $\pi_3$  will refine  $\pi_4$  or  $\pi_5$ ,  $\pi_4$  will not refine  $\pi_3$  it is not breaking up like that so this will induce a partial order like this.  $\pi_2$  will be the lowest one or the least element,  $\pi_3$ ,  $\pi_4$  and  $\pi_5$  and  $\pi_1$  is refined by everything. So this is a partial order it is a poset diagram or a Hasse diagram  $\pi_2$  refines  $\pi_3$ ,  $\pi_2$  refines  $\pi_4$ ,  $\pi_2$  refines  $\pi_5$  and by transitivity  $\pi_2$  refines  $\pi_1$  and  $\pi_3$ ,  $\pi_4$ ,  $\pi_5$  refine  $\pi_1$  but  $\pi_3$  and  $\pi_4$  there is no connection  $\pi_4$  and  $\pi_5$  there is no connection and so on. So it is represented by a partial order like this.

(Refer Slide Time: 43:54min)

Next we shall see what is meant by the product of two partitions.

(Refer Slide Time: 43:57min)

Let  $\pi_1$  and  $\pi_2$  be partitions of a nonempty set  $A$ . the product of  $\pi_1, \pi_2$  denoted by  $\pi_1 \cdot \pi_2$  is a partition  $\pi$  of  $A$  such that  $\pi$  refines both  $\pi_1$  and  $\pi_2$ . If  $\pi'$  refines both  $\pi_1$  and  $\pi_2$  then  $\pi'$  refines  $\pi$ . So let us see what is meant by the product of a partition. Let a b c d be a set, this is a set and  $\pi_1$  a partition like this a, b in one block c, d, e in one block and f in one block, this is  $\pi_1$ . And  $\pi_2$  is, a, b in one block and c, d in one block and e, f in one block, so this is an example.

What do you mean by the product of  $\pi_1$  and  $\pi_2$ ?

$\pi_1$  we have represented like this, sometimes you represent like this the product of  $\pi_1$  and  $\pi_2$ .

What is this?

This is a partition  $\pi$  such that  $\pi$  should refine both  $\pi_1$  and  $\pi_2$  and any other partition which refines both  $\pi_1$  and  $\pi_2$  should refine  $\pi$  also, so it is obtained like this. So consider this in this example; a, b is a block here a, b is also a block so that will be retained as it is. Now, c, d is one block, c and d are in the same block here so c, d again will be a block here. But e, f is in one block here, e and f are in different blocks here so you cannot have e, f in one block e will be in a separate block f will be in a separate block. Here you have to split c, d, e will be split as c, d and e and e, f here will be split as e and f.

Now you see that this one refines  $\pi_1$ . Each block is contained in a block of this, this also refines  $\pi_2$ . So you see that  $\pi$  refines both  $\pi_1$  and  $\pi_2$  and if you take say  $\pi$  dash is equal to a, b, c, d, e, f this is some other partition you see that  $\pi$  dash refines  $\pi_1$  and  $\pi$  dash also refines  $\pi_2$  you see that  $\pi$  dash also refines  $\pi$  so that is the condition. The product of two partitions  $\pi_1$  and  $\pi_2$  which is denoted as  $\pi$  refines both  $\pi_1$  and  $\pi_2$ . And if  $\pi$  dash refines both  $\pi_1$  and  $\pi_2$  then  $\pi$  dash refines  $\pi$ .

(Refer Slide Time: 46.54min)

$$\begin{aligned} A &= \{a, b, c, d, e, f\} \\ \pi_1 &= \{\overline{a, b}, \overline{c, d}, \overline{e}, \overline{f}\} \\ \pi_2 &= \{\overline{a, b}, \overline{c, d}, \overline{e, f}\} \\ \pi_1 \cdot \pi_2 &= \pi \\ &= \{\overline{a, b}, \overline{c, d}, \overline{e}, \overline{f}\} \\ \pi' &= \{\overline{a, b}, \overline{c, d}, \overline{e}, \overline{f}\} \end{aligned}$$

Now what is the connection between this and the equivalence class is represented by them?

Let  $R_1$  and  $R_2$  be the equivalence relations induced by the partitions  $\pi_1$  and  $\pi_2$  of a nonempty set  $A$ . Then the relation  $R$  is equal to  $R_1$  intersection  $R_2$  induces a product partition  $\pi$  of  $\pi_1$  and  $\pi_2$ . So, if this induces the equivalence relation that equivalence relation will have three components, what are the components here? Corresponding to  $\pi_1$  if you have  $R_1$  then  $R_1$  will have a, b the equivalence relation can be represented like this

then  $c, d, e$  and  $f$  and  $R_2$  will be represented by  $a, b, c, d, e, f$  and  $\pi$  induces  $R$  that will be  $a, b, c, d$  and  $e$  and  $f$ .

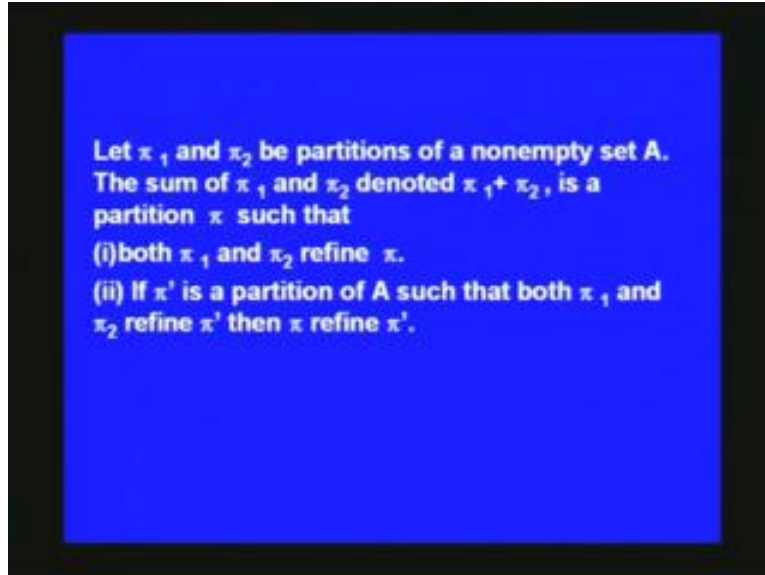

You can see that the intersection of these two is this. See, this is present here, this is present here, it is present here and  $c, d$  this is present here, this is also present here it is present here and the other elements which are not present in this are removed and you have a self loop at  $e$  and  $f$ . So the intersection of  $R_1 \cap R_2$  is  $R$  which is the equivalence relation induced by the product of  $\pi_1$  and  $\pi_2$  induced by  $\pi$ .

(Refer Slide Time: 49.26min)

Now we will see what is meant by the sum of two partitions?

(Refer Slide Time: 49.37min)

Let  $\pi_1$  and  $\pi_2$  be partitions of a nonempty set  $A$ , then the sum of  $\pi_1$  and  $\pi_2$  denoted by  $\pi_1$  plus  $\pi_2$  is a partition  $\pi$  such that both  $\pi_1$  and  $\pi_2$  refine  $\pi$  if  $\pi$  dash is a partition of  $A$  such that both  $\pi_1$  and  $\pi_2$  refine  $\pi$  dash then  $\pi$  refines  $\pi$  dash.

Take the same example here,  $A$  is a set like this  $\pi_1$  and  $\pi_2$  are partitions like this. The sum of these two  $\pi_1$   $\pi_2$  is a partition  $\pi$  such that both  $\pi_1$  and  $\pi_2$  will refine  $\pi$ . So here  $a$ ,  $b$  is a block here  $a$ ,  $b$  is a block here so that will be in one block. Then  $c$ ,  $d$  is in one block here but  $c$ ,  $d$  is in block which also contains  $e$  so you have to include that also here. And here  $e$  and  $f$  are in the same block so you have to include that also here. So this is the sum of  $\pi_1$  and  $\pi_2$   $a$ ,  $b$  will be in one block and  $c$ ,  $d$ ,  $e$ ,  $f$  will be in another block.

Now you see that  $\pi_1$  refines this  $\pi_2$  also refines this. If I take another one say the whole set  $a$ ,  $b$ ,  $c$ ,  $d$ ,  $e$ ,  $f$  in one block  $\pi_1$  and  $\pi_2$  refine this but you note that  $\pi$  also refine this. So if there is another partition which is refined by  $\pi_1$  and  $\pi_2$  it will be refined by this sum also. So that is the definition of this.

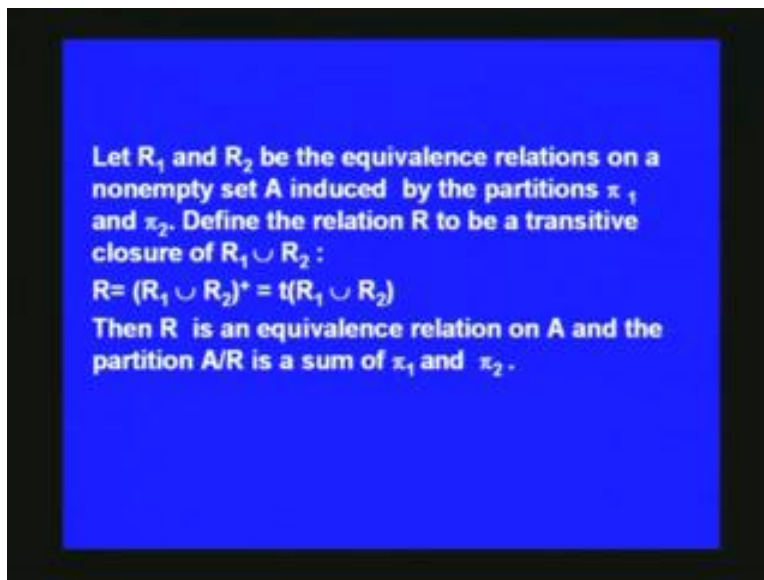

(Refer Slide Time: 51.35min)

And what is the connection between these equivalence relations?

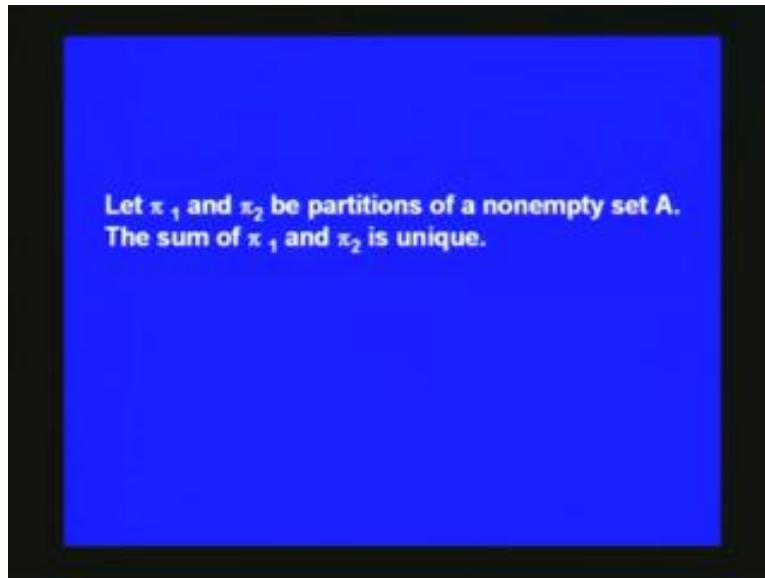

(Refer Slide Time: 51.39min)

Let  $R_1$  and  $R_2$  be the equivalence relation on a nonempty set  $A$  induced by the partitions  $\pi_1$  and  $\pi_2$ . Now, we have seen that  $R_1$  and  $R_2$  are equivalence relations but  $R_1$  union  $R_2$  need not be an equivalence relation. Now,  $\pi_1$  will induce an equivalence relation  $R_1$ ,  $\pi_2$  will induce an equivalence relation  $R_2$  we have seen what is that in this example  $R_1$  is this and  $R_2$  is this. Now  $\pi$  induces another equivalence relation but you see that  $R_1$  union  $R_2$  need not be an equivalence relation.

But what is the equivalence relation induced by  $\pi_i$ ? That is  $R$  and in this case it will be  $a, b$  and  $c, d, e, f$  in one block and the self loops all over like this. This is the equivalence relation  $R$  induced by  $\pi_i$  and it is the transitive closure of  $R_1 \cup R_2$ . If you take the transitive closure of  $R_1 \cup R_2$  that is the equivalence relation induced by the sum partition.  $R_1 \cup R_2$  plus is equal to  $t$  of  $R_1 \cup R_2$ . Then  $R$  is an equivalence relation on  $A$  and the partition  $A$  by  $R$  is the sum of  $\pi_1$  and  $\pi_2$ .

(Refer Slide Time: 53.36min)

Now if you have two partitions  $\pi_1$  and  $\pi_2$  the sum is unique you cannot have two different sums why?

If I have  $\pi$  dash as the sum of  $\pi_1$  I have two partitions  $\pi_1$  and  $\pi_2$  the sum of  $\pi_1$  and  $\pi_2$  is unique why? If I have two of them say  $\pi$  dash of two sums say  $\pi$  dash and  $\pi_2$  dash this will refine this by definition and this will refine this. That means  $\pi$  dash is equal to  $\pi$  you cannot have two different sums they will be equal. And similarly, the product of two partitions if you have two partitions  $\pi_1$  and  $\pi_2$  the product of the partition is denoted by this you can have only one product. If  $\pi$  dash and  $\pi_2$  dash are two products like that  $\pi$  dash will refine  $\pi_2$  dash and  $\pi_2$  dash will refine  $\pi$  dash by the definition and so they will be equal so the product is also unique.

(Refer Slide Time: 55.09min)

So we have seen the equivalence relation in detail. This has got a lot of application in several fields of Computer Science. And we have also seen the connection between partitions and equivalence relations and what is meant by the product of partitions, sum of partitions and how they induce new equivalence relations on the underlying set.
