Introduction to mobile apps

(Refer Slide Time: 00:05)

What is a mobile app?

- Any app that runs on a mobile device, typically a smartphone, is a mobile app
- Unlike a webapp (which runs in a browser) a mobile app runs directly on the OS
- Different mobile OSs popular today:
 - Android
 - iOS
 - Windows 10 mobile
- Older
 - Blackberry OS
 - Palm OS/Bada etc.
 - Symbian
- A mobile app may or may not need the Internet to work
- A mobile app is typically downloaded from official app stores

In this module in the short module we are going to take a quick introduction to mobile apps. So, a mobile app is actually any app that runs on a mobile device it typically runs on a Smartphone unlike a web app which runs in a browser a mobile app runs directly on the operating system mobile app may not actually need to connect to the internet to work. For example, games or also mobile apps and they might not need to connect to the internet to love the user play the game, unlike a web app which is used by going to a particular website or a domain name, a mobile app is typically downloaded from official app stores. So, popular mobile operating systems today are android, iOS in windows ten some older mobile operating systems that used to exist or Blackberry OS, Palm OS, Bada and Symbian for Nokia.

Client server architecture

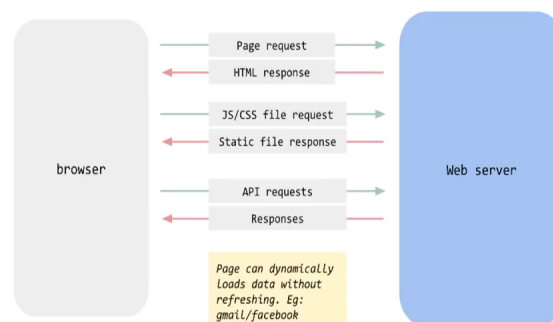

Introduction to Modern Application Development

Dr Gaurav Raina (IIT Madras), Tanmai Gopal (Hasura)

If we remember the client server architecture we have the client on the right that makes you requests. So, the network to the server and the server response back through the network so that was the client server architecture that we have understood in a fair amount of detail so far.

(Refer Slide Time: 00:54)

Traditional webapp architecture

Introduction to Modern Application Development

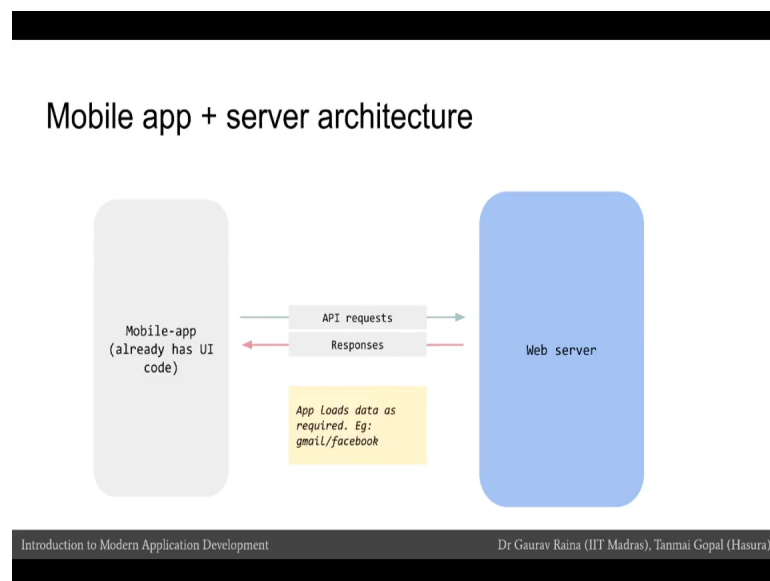

Dr Gaurav Raina (IIT Madras), Tanmai Gopal (Hasura)

A traditional web app works as follows. So, on the left there is a web app that is making a request to the web server on the right. The first thing the browser is used for is making a page request. So, we say for example, we say let us go to Google dot com. So, it

requests a particular page the web server response only with HTML data the HTML contains links to JavaScript and CSS file. So, the browser passes that HTML figures out that it needs to make request to JavaScript and CSS files makes those request the web server.

The web server response with those particular static files and the browser injects those files into the context of the HTML page that it is created so far or the web app source code might make further API request. So, the web server and the web server would respond with responses typically in JSON or XML and this is the way that a page can dynamically load data and it does not even need to refresh as the user browses the particular page or uses the app. So, for example, if we use modern applications like Gmail and Facebook you will notice that the pages almost never go through a full refresh and all of the content keeps changing while the user is on that same page itself.

(Refer Slide Time: 02:06)

Mobile app works a little differently in the case of a mobile app mobile app is downloaded on the mobile phone mobile app already has the UI code. So, it is not need to make a request the web server to fetch the UI code; however, a mobile app may necked API request the web server and the web server we will respond with data that the mobile app can use to change its content dynamically. So, Gmail and Facebook apps have the UI in built in to the app, but they contact the web server to fetch emails or new emails or fetch new items from the news feed which requires an internet connection.

Mobile app vs webapp: Technical differences

Web	Mobile
App loads in a browser	App is installed and runs on the OS
App fetches UI code (HTML/CSS/JS) from a web-server	App comes with UI code (Android - Java, iOS - ObjectiveC/Swift)
App UI can be updated instantly (just change the code on the server)	App cannot be updated automatically. User has to update the app (or tell the app store to automatically update the app)
App is sandboxed from the OS and can only access the resources the browser allows it to access	App can access all the resources that the OS allows: sensors, GPU etc.

Introduction to Modern Application Development

Dr Gaurav Raina (IIT Madras), Tanmai Gopal (Hasura)

So, the technical differences between the mobile app and the web app can be listed as follows web app runs in a browser whereas, a mobile app runs directly on the operating system the app fetches UI code from a web server and the UI code is written in HTML CSS and JavaScript. On a mobile app the app contains the UI code so for android the code is written in the java language and for iOS code is written in objective c or the swift language web app UI can be updated instantly. So, for example, if you want to update what a page looks like all we need to go and do is change the end point that is handling that particular page and that way the UI will get updated instantly.

However mobile apps cannot be updated automatically by the developers the user has to update the app or has to tell the app store to automatically update the app and only then we will the new UI sort of be available to the user. In web apps the app is sandboxed from the operating system so that means, that the web app can only access those resources that the browser allows the web app to access; however, in a mobile app the access the mobile app can access all resources with the operating system allow. So, for example, sensors GPU is external devices all of these are possible for mobile app to access.

Mobile app vs webapp: Practical differences

- Webapps are easy-come, easy-go
- Mobile apps have to be 'downloaded' & 'installed'
- Mobile apps today still have a smoother UI/UX especially when using device hardware/sensors
 - But the gap is steadily narrowing
- Most popular types of mobile apps for a generic consumer:
 - Games
 - Apps that are used everyday, not occasionally: Browser, Facebook, Whatsapp, Uber/Ola
- Building & maintaining a mobile app is significantly harder than a webapp
 - Think about the use case carefully
 - Make sure that your target customer derives a huge amount of value from it Eg: shazzam
 - OR make sure that your target customer will be using it atleast once a day
- Not true for games and apps that suddenly go 'viral' :)

Practically this boils down to quite a few differences between the mobile app and the web app most web apps are easy come easy go meaning its very for users to visit a web app use it and then they will forget about the web app is well.

However mobile apps have to be downloaded and installed; that means, it is much harder to get users to use mobile app because there is a lot of friction or inconvenience in going and downloading an app this has business implications, this has business implications. Mobile apps today have a smoother UI and UX especially because they are able to use device hardware especially when the app uses device hardware or sensors, but the gap between the experience of mobile app and web app is steadily narrowing as browsers on the mobile become much better.

The most popular types of mobile apps for a generic consumer or games or apps that are used everyday not apps that are used occasionally for example, the web browser is a mobile app Facebook, Whatsapp, apps like Uber and Ola; these are used very frequently and these kinds of apps a very popular candidates for mobile apps. Building and maintaining a mobile app is significantly harder than a web app, so if we are developers in a team that is building a mobile app we should think about the use case very very carefully we should make sure that the target consumer that is using the mobile app did I have a huge value. So, even if the mobile app is not being used every day the value that is provide from the mobile apps should be men. So, for examples Shazzam is a mobile

app that allows you to take your phone and listen to a song that is playing on a speaker and the app tells you the song that is playing.

In case the amount of value that is provided by the mobile app is not huge we should teach make sure that our target customer will be using the mobile app at least once a day. So, that the user does not feel like deleting the mobile app from his or her phone. Now these points that I have talked about so far are more business and product development related points and these points might change in the future as mobile phones become better and as browser become better.

(Refer Slide Time: 06:01)

Key points & Going forward

- We understand in-principle at least what a mobile app looks like and how it "should" work based on what we understand about client-server architectures
 - UI is written in a different programming language (as opposed to HTML/CSS)
 - A way to specify structure
 - A way to specify styling info
 - Interactivity and server interactions (APIs) are written in a different programming language (as opposed to JS)
 - Equivalent of onclick handlers
 - Equivalent of AJAX HTTP request
 - But all the same principles! It's just a new programming language
- We know what a mobile app is, vis-a-vis a webapp
- In one of the next few practical modules, we'll take a look at some Android/iOS code and the experience of building a mobile app!

Key points to take away from these quick such a points are to understand that in principle we have a clear understanding of what a mobile app looks like we also know what it should what a mobile app should look like. So, for example, we know that if the mobile app has a UI component it must have some equivalent of HTML CSS that allow us to write the UI. We know that a mobile app if it has features that provide the interactive it to the user or talk to the server to fetch data they must at the equivalent of onclick handle us that we used in JavaScript or must have an equivalent of AJAX and HTTP request.

So, the same principles applied to a mobile app as a web app; however, the programming language and their environment is a little different. In some of the next few practical

modules we will be taking a look at some android and iOS code and what the experience of building a mobile app is like.
