Social Networks Prof. S. R. S. Iyengar Department of Computer Science Indian Institute of Technology, Ropar

Cascading Behavior in Networks Lecture - 99 Coding the Third Big Idea- Impact of Communities on Cascades

(Refer Slide Time: 00:05)

Now, we are going to talk about the third idea which is very cute which says that if you have many communities in your network. So, for the sake of simplicity, we will take two communities and we show that if our cascade starts from one community; then it actually even if it gets into this entire community, it is difficult for this cascade to get into another community. So, we will be coding and now we will be looking at this aspect.

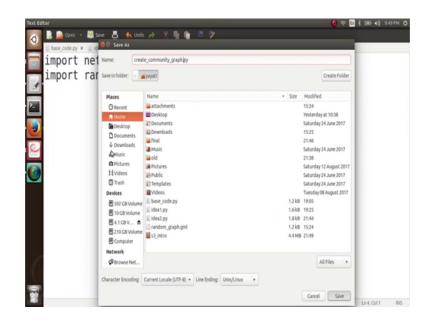

(Refer Slide Time: 00:31)

So, for implementing this, we need a graph which consist of two communities; two dense communities. So, what will we do? What will we do? We will create an artificial graph which will be consisting of two communities. How do we create this artificial graph is we will create a graph having 20 nodes. So, first 10 nodes will be connected to each other and second 10 nodes means nodes 0 to 9 will be connected to each other and node 10 to 19 will be connected to each other and there will be just one link between these two communities.

Let us just quickly do it. So, I will just import networkx as nx and I will also need the random functions. So, a import random as well.

(Refer Slide Time: 01:24)

Let me save this as this file as create community graph dot py ok. So, I import it random and then what I will do is I create a graph G equals to nx dot graph. After this I create the first community in this graph. So, I call the function create first community and what does this function do is, it just creates a random links between the people I will just show you. So, define, create, first community and we pass the graph here first community G and what you do here is ok. So, first of all I add 10 nodes in this community and no edge is. So, for i in range 0 to 10, what do I do is G dot add node i. So, I have added 10 nodes in this graph, next I want to add some links.

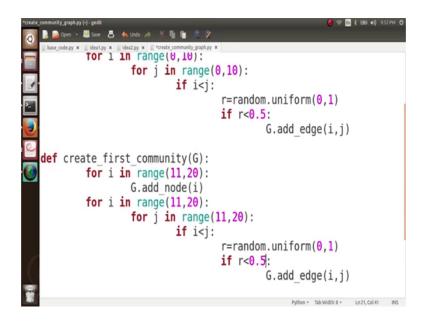

So, how do I add some links? For as we know these are 10 nodes and there are 10 chose to possible edges between these nodes. So, I will take every edge and I will put every edge with the probability of 0.5. So, I am doing exactly what happens in an Erdos Renyi graph, but I am just coding it manually. So, for i in range 0 to 0 so, I will put first iterator over all of these nodes and then for j in range 0 to 10, I put a second iterator here and again to avoid duplication and the same number if i is less than j so, that I get every pair only once.

What do I do? I will want to put an edge here with the probability of 0.5 and I am quite sure that you know what I am going to do next because we have seen it previously. We have coded it also previously. If I want to do some event with a particular probability, I create a random number; random uniform number real number from 0 to 1. So, I will get

a real number from 0 to 1 r equals to random dot uniform random dot uniform 0 to 1 and then if r is less than 0.5. What I do is G dot add edge form i to j.

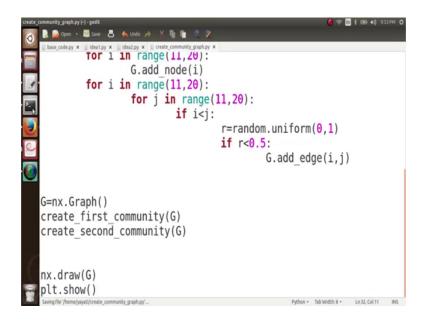

So, I have added every possible edge between these 10 nodes with the probability of 0.5. So, this is my first community. Similarly I will create my second community. Create second community and I am sure that you know that the code is going to be same except for the numbering of nodes.

(Refer Slide Time: 04:45)

So, we can just copy paste this code here and what I can do is I know that my nodes are now going to run from 11 to 20 right. So, from 11 to 20 and here also 11 to 20 and here also 11 to 20, everything is done. So, 10 nodes I created here in the; similar way 10 nodes, I created here and between these 10 nodes. I will again put an edge with the probability of 0.5.

(Refer Slide Time: 05:11)

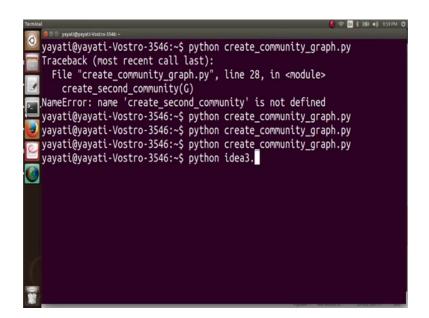

So, what am I going to have now in my network, there will be two separate communities or you can say two components in this graph. So, what currently we have made is a disconnected graph. I can also actually show you this graph. So, let me show you this graph nx dot draw G, then we have a plt dot show right and let us run.

(Refer Slide Time: 05:48)

It create community graph.

(Refer Slide Time: 05:52)

I am just create.

(Refer Slide Time: 06:01)

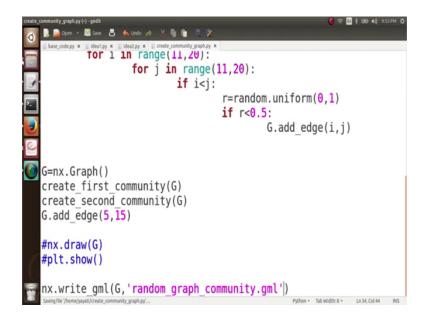

We forgot to change the name of function here. So, it is create second community. So, you can see this graph here right. We have one community here having which is actually random graph with the 10 nodes and 0.5 probability and one community here.

Now, these are actually components we cannot say these are communities also, but they are components; we want a connected graph. So, what I am going to put next is I am

going to put just one edge between these two communities. So, that the communities in my graph are very very well defined; I put only 1 edge.

(Refer Slide Time: 06:42)

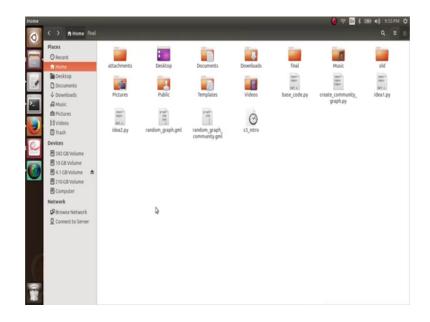

So, I what do I do is G dot add edge and I add an edge.

Student: (Refer Time: 06:48).

Let us say from node 5 to 15. So, let us run it. So, you can see here now this is my graph having two communities. We are going to work with this graph for a third idea, for the implementation of the third idea. What I will do is, I store this graph nx dot write gml and I store this graph as let me name it as random graph with community. So, random graph community dot sorry dot gml right dot gml; I run it.

(Refer Slide Time: 07:41)

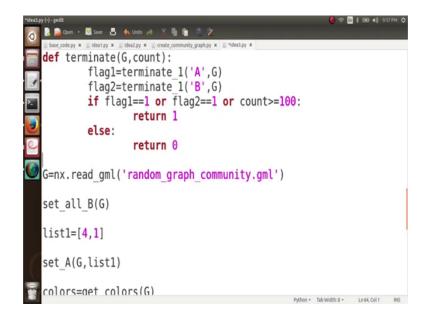

So, you can see a graph here random graph community dot gml ok. So, now, we are ready to see the. So, we have a graph with community and we are ready to see the impact of cascading on such a network.

So, I will actually take my code from here and. Take my code from here and let us save it here. We will do all the changes here. Let us call it idea 3 dot py.

(Refer Slide Time: 08:13)

So, first of all which is the graph we are going to work with this random underscore graph underscore community one thing and then let us change the payoffs little bit or let us keep it the say.

(Refer Slide Time: 08:26)

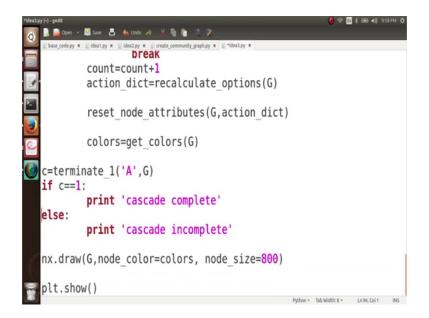

So, let the payoffs be 10 and 5 and let my starting nodes be 0 and 1.

(Refer Slide Time: 08:36)

And what I am interested in is looking at how will this cascade going to occur.

(Refer Slide Time: 08:42)

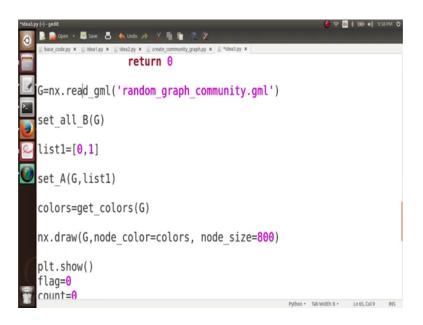

And let me look at this in every step.

(Refer Slide Time: 08:48)

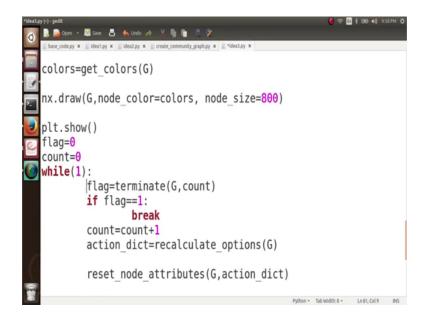

I want to see the graph at every step. So, you can see I will just show you the code. It is the same code which we have written previously.

(Refer Slide Time: 08:58)

So, here we load a graph. Here we set all the nodes to have the action B, here we choose the initial adopters. We set the initial adopters, we draw the graph.

(Refer Slide Time: 09:09)

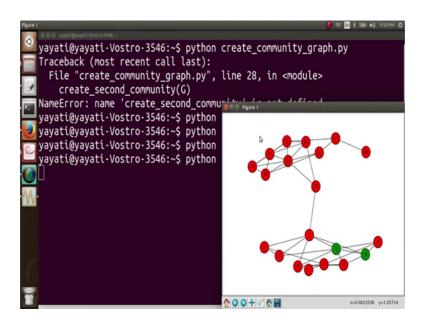

Next, this is just a while loop in which are process runs again and again. Terminating condition, as we have discussed before action dictionary we calculate the next snapshot and then we upload the next snapshot exactly what we want to do.

(Refer Slide Time: 09:25)

etse.	<pre>print 'cascade incomplete'</pre>	
nx.draw	(G,node_color=colors, node_size=800)	
plt.sho		Tab Width: 8 • Ln 102, Col 1 INS

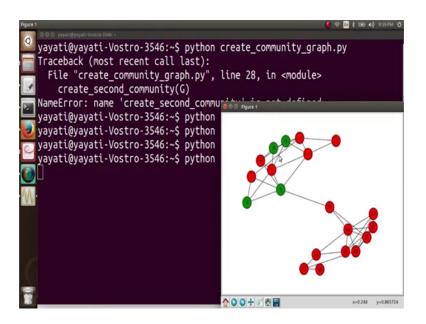

So, we just the code is very very simple, we just have to run this code and see what happens. So, let us implement it let us execute it python idea 3 dot py ok.

(Refer Slide Time: 09:37)

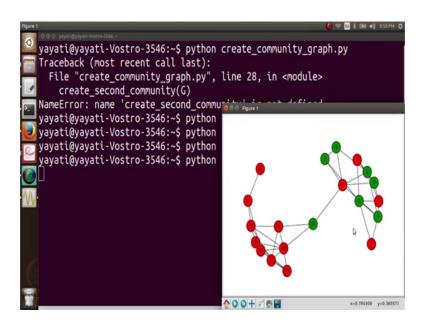

So, this is your initial graph and the nodes 0 and 1 are infected here.

(Refer Slide Time: 09:44)

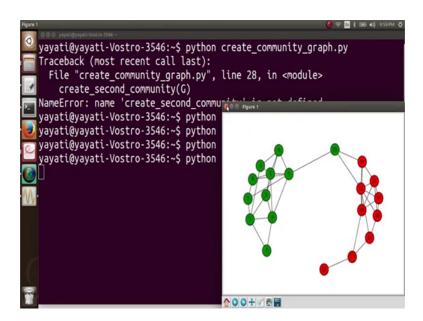

I have adopted the idea and then you can see that 0 and 1 have adopted back the behavior B, but these other four nodes in this community have adopted this behavior A.

(Refer Slide Time: 09:56)

And then you see more nodes have adopted this behavior A and this one node in this community have also adopted this behavior A and then you can see that most of the nodes in this first community where the cascade started have adopted the behavior A.

(Refer Slide Time: 10:12)

And then you see, one community has completely adopted the behavior A while in other communities still everybody has adopted just the behavior B. And you can keep running it again and again and you can see that this behavior you not passing on to the other

community. It remains struck to this first community only. We can see that this cascade it keeps strapped in the first community itself.

So, this graph is not going to change, it will just keep running for hundred iterations like this and your cascade has actually come to an end. So, if you remember during the lecture we discussed that there is this, there are three stability conditions: first is everybody in this network adopts A, second is everybody in this network adopts B and third is some nodes in this network adopt a while others adopt B. So, you can see that is the third condition here.

Some nodes in this network have adopted A, other nodes in this network have adopted B and then we have looked at what should the network look like for the third condition to happen and that was the presence of communities and that is exactly what is happening here. Here are two communities one community has adopted one behavior and the second community has adopted a different behavior.
