So we have seen what the binomial theorem states. Let us now see some beautiful applications of it. You all must have heard of  $1 + x^n$ . When I apply binomial theorem on this let us see what the terms are;  $1 + x^n$  becomes  $\binom{n}{0} 1^n x^0 + \binom{n}{1} 1^{n-1} x^1 + \binom{n}{2} 1^{n-2} x^2 + \dots + \binom{n}{n} 1^0 x^n$ . When I expand this I will get  $\binom{n}{0}$  to be 1,  $1^n$  is again 1 into  $1 + \binom{n}{1}$  is 1 plus again 1 to the  $n-1$  becomes 1 into  $1 + \binom{n}{1}$  becomes  $n$  into  $1 + \binom{n}{2}$  can be written as  $n$  into  $n-1$  by 2. I have written this by simplifying  $\binom{n}{2}$  into  $1 + \binom{n}{3}$  can be written as  $n$  factorial by 3 factorial into  $n-3$  factorial into  $1 + \binom{n}{4}$  can be written as  $n$  factorial by 4 factorial into  $n-4$  factorial into  $1 + \dots$ . This becomes  $1 + x^n$  the ends get canceled here plus I'll cancel  $1^n$  from the denominator and the numerator and what remains is  $n-2$  by 2 into  $n$  and now simplifying the next term we get  $n$  into  $n-1$  into  $n-2$  by 3 factorial into  $1 + \dots$  plus so on.

Now this becomes  $1 + x^n$  plus let me take a  $n$  common from the numerator here and this becomes  $n$  into  $1 - 1$  by  $n$  by 2 into  $n$  plus we have  $n$  here and  $n$  cube here so after simplification what remains is  $n-1$  into  $n-2$  by  $n$  square into 3 factorial and so on. Now this one I'll write it as 0 factorial and this I will write it as 1 by 1 factorial plus. You will understand why I'm writing like this, plus I cancel these ends here and I get  $1 - 1$  by  $n$  by 2 is same as 2 factorial and hence I'll write this as 2 factorial plus again as I did earlier I'll take out ends common in these two terms so I will get  $n$  into  $1 - 1$  by  $n$  into  $n-1$  into  $n-2$  by  $n$ . I hope the step was clear, by  $n$  square into 3 factorial plus so on.

Now I'll cancel these ends with  $n$  square and what remains is zero factorial as we have seen earlier is one so it does not make a difference if I write  $1$  by  $0$  factorial plus  $1$  by  $1$  factorial plus  $1$  minus  $2$  by  $n$  by  $2$  factorial plus  $1$  minus  $1$  by  $n$  into  $1$  minus  $2$  by  $n$  by  $3$  factorial and so on. Now what happens to these terms when  $n$  becomes sufficiently large? What I mean by sufficiently large is we have to choose  $n$  to be a very large number. In case  $n$  happens to be a very large number then  $1$  by  $n$  or  $2$  by  $n$  or any small number by  $n$  becomes very close to  $0$  and hence this term can be written as  $1$  by  $0$  factorial plus  $1$  by  $1$  factorial plus I am approximating this  $2$  by  $n$  to be a number very small very close to  $0$  and hence this becomes  $1$  by  $2$  factorial.

I'm neglecting the terms which have denominator as  $n$  and hence in all the further terms what will I get? It will become  $1$  by  $3$  factorial plus  $1$  by  $4$  factorial and so on. So this becomes summation  $1$  by  $K$  factorial  $K$  from  $0$  to infinity. Now this is called the famous Euler's number. I'm sure you must have heard of  $e$  and this we have arrived at this by starting from expanding  $1$  plus  $1$  by  $n$  whole to the  $n$  by using binomial theorem. So this was one application of binomial theorem.

Now let us see the next one. The derivative of  $X$  to the  $n$  involves binomial theorem. Now derivative is a concept from calculus and I am talking of binomial theorem. So how is it related? The proof involves certain technicalities from calculus and I leave it to you guys to go and check it. I am not giving the proof of the derivative of  $X$  to the  $n$  here but let me state it. The derivative of  $X$  to the  $n$  is  $n$  into  $X$  to the power  $n$  minus  $1$  and this involves the usage of binomial theorem. Let us move on to the next one. We know that binomial theorem states that  $x$  plus  $y$  whole to the  $n$  is summation  $K$  from  $0$  to  $n$ ,  $nCK$  into  $x$  bar  $n$  minus  $K$  in the  $y$  power  $K$ . What happens when I plug in  $x$  and  $y$  as  $1$ ? So it becomes  $1$  plus  $1$  whole power  $n$  equals summation  $K$  from  $0$  to  $n$   $nCK$ . So in place of  $x$  and  $y$  I am writing it as  $1$  and hence this becomes  $1$  to the  $n$  minus  $K$  into  $1$  to the  $K$ . Now you must be wondering why I am doing this because I'm just plugging in  $1$  for  $x$  and  $y$  but let me tell you this is  $2$  power  $n$  equals summation  $K$  from  $0$  to  $n$   $nCK$ . So did you observe what happened? We have as a summation only the binomial coefficients and the sum of all these binomial coefficients turns out to be  $2$  power  $n$ . What does this actually mean? If we have  $n$  objects each time we choose  $K$  objects from these  $n$  objects like I'm choosing  $0$  from  $n$  objects, I'm choosing one object from  $n$  objects, two objects from  $n$  objects and so on and I add up all this so what it becomes, it results in  $2$  power  $n$ . Did you see the beautiful connection between binomial theorem and choosing objects from  $n$  objects and  $2$  power  $n$ .

So these were a few applications of binomial theorem. Next we'll move on to the generalization of binomial theorem and solve a lot of problems.
