Polynomial Time Reductions - Part 2

(Refer Slide Time: 00:17)

Theorem 7.32: $3\text{-SAT} \leq_p \text{CLIQUE}$

$3\text{-SAT} = \{ \langle \phi \rangle \mid \phi \text{ is a 3-CNF formula, } \phi \text{ is satisfiable} \}$

$\text{CLIQUE} = \{ \langle G, k \rangle \mid G \text{ is an undirected graph with a } k\text{-clique} \}$

Suppose ϕ has n variables m clauses.
 $\phi = (a_1 \vee b_1 \vee c_1) \wedge (a_2 \vee b_2 \vee c_2) \wedge \dots \wedge (a_m \vee b_m \vee c_m)$

where each a_i, b_i, c_i are a literal (x_i / \bar{x}_i).

Given ϕ , we need to construct a CLIQUE instance $\langle G, k \rangle$ such that

$\phi \text{ is satisfiable} \iff \langle G, k \rangle \in \text{CLIQUE}$

Suppose ϕ has n variables m clauses.
 $\phi = (a_1 \vee b_1 \vee c_1) \wedge (a_2 \vee b_2 \vee c_2) \wedge \dots \wedge (a_m \vee b_m \vee c_m)$

where each a_i, b_i, c_i are a literal (x_i / \bar{x}_i).

Given ϕ , we need to construct a CLIQUE instance $\langle G, k \rangle$ such that

$\phi \in 3\text{-SAT} \iff \langle G, k \rangle \in \text{CLIQUE}$

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$.

So, the next thing that I want to show is a proof that 3 SAT reduces to CLIQUE. So, 3 SAT we have seen it is a class of all Boolean formula, which are in 3 CNF form and are satisfiable, so 3 CNF means this, you have AND of clauses were each clause is an OR of literals. So, 3 SAT means it is a 3 CNF formula that is satisfiable.

(Refer Slide Time: 00:58)

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$.

ϕ is satisfiable?

$CLIQUE = \{ \langle G, k \rangle \mid G \text{ is an undirected graph with a } k\text{-clique} \}$

Suppose ϕ has n variables in clauses.

$$\phi = (a_1 \vee b_1 \vee c_1) \wedge (a_2 \vee b_2 \vee c_2) \wedge \dots \wedge (a_m \vee b_m \vee c_m)$$

where each a_i, b_i, c_i are a literal (x_i / \bar{x}_i).

Given ϕ , we need to construct a CLIQUE instance $\langle G, k \rangle$ such that

$$\phi \in 3\text{-SAT} \Leftrightarrow \langle G, k \rangle \in CLIQUE$$

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$.

So, CLIQUE is a graph whose all the edges are adjacent. So, for instance, in this graph, the graph that I am just drawing in the corner here, there is a 4 CLIQUE, which of these 4 vertices constitute a 4 CLIQUE. Because if you take these circle vertices, you take any pair of them they are adjacent this and this is adjacent this and this any pair is adjacent.

So, there are 6 possible 1, 2, 3, 4, 5, 6, 6 possible adjacent is there and all 6 exist. So, which means this graph has a 4 CLIQUE, but it does not have it 5 CLIQUE, there are no set of 5 vertices that are adjacent to each other like this. So, the CLIQUE consists of a pair G and K , where G is an undirected graph with K CLIQUE.

So, if this graph that is that we have drawn over here, is given with the number 4, it will be yes instance with K equal to 4. But if it is given with the number 5, it will be no instance because

there is no CLIQUE of size 5, if it is given with the number 3, again, it is a yes instance, because you could take these 3 vertices, and that is a 3, CLIQUE. So that is the problem of CLIQUE.

So given a graph G and a number K , you are asking whether there is a K CLIQUE. And 3 SAT I already mentioned. So, it may be a bit surprising that one of them is a problem on Boolean formulas and satisfiability. The other one is something about graphs and having some number of vertices that are adjacent to each other.

How is it possible that you can transform 1 to other? So that may seem very surprising, so it is not that hard. So, we will see the reduction and maybe another next 15 minutes. So, before that, we will just set up some basic notation. So, let n be the number of variables of the, so what do we have to do? We have to given a 3 SAT instance we have to obtain a CLIQUE instance.

So, if the given 3 SAT instance is satisfiable, then the output CLIQUE instance should be a yes instance, if the given 3 SAT instance is not satisfiable, the output CLIQUE instance should not be yes instance. So, it should be a pair G and K where G does not have a K clique So, how can we do this? So, suppose, we say that n is the number of variables of the given formula, and m is the number of clauses.

So remember, the Boolean formula is 3 CNF form, where we have AND of clauses, where each clause is an OR of literals. And, and further, each clause is an OR of 3 literals. So you will have $(a_1 \vee b_1 \vee c_1) \wedge (a_2 \vee b_2 \vee c_2) \wedge \dots \wedge (a_m \vee b_m \vee c_m)$. So, this is how the how the formula will look like. Where each of a_1, b_1, c_1 maybe $x_1, \bar{x}_1, x_2, \bar{x}_2, x_3, \bar{x}_3$ anything or x_j, \bar{x}_j in general.

So, given this, we need to construct an output something of the form $\langle G, K \rangle$, such that this formula is satisfiable if and only if this $\langle G, K \rangle$ is yes instance of CLIQUE or in other words, G has a K clique. So it is easiest to explain this reduction through an example.

(Refer Slide Time: 04:48)

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$.

G has 3 m vertices, where m is the number of literals in ϕ .

And since there are I want to draw the picture and explain this example, I am going to resort to a very simple, simplistic kind of formula, but it should be very easy to see how we can deal with a bigger formula as well. Just that the figure will get much more messier. But just for the purpose of understanding this reduction, the example that we are taking is representative enough.

So, suppose ϕ

$$\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$$

So, we have only 2 variables x_1 and x_2 . And we have only 3 clauses. So, n is 2, m is 3. And this is a property of 3 SAT, every clause has 3 literals,

So, given this, our goal is to produce G and m such that this is satisfiable if and only if G has a m CLIQUE. So, let us see how it happens. So, first, the graph G looks like this. So, what do we have here? So, we have 3 groups of vertices. So, the group by group, this is group 1, this is group 2, and this is group 3, and each group has 3 vertices each.

(Refer Slide Time: 06:24)

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

G has $3m$ vertices, where m is the number of clauses. Each clause is connected to m vertices.

So, basically, we have 3 groups of vertices, because we have 3 clauses in the formula. So, here we have 3 clauses.

(Refer Slide Time: 06:27)

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

G has $3m$ vertices, where m is the number of clauses. Each clause is connected to m vertices.

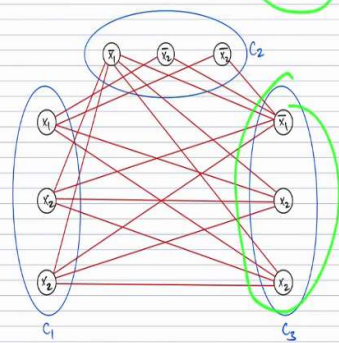

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$.

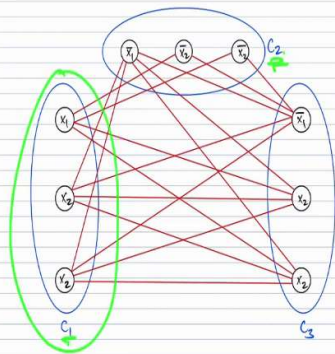

G has $3m$ vertices, where m is the number of clauses. Each clause corresponds to a set of 3 vertices.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$.

G has $3m$ vertices, where m is the number of clauses. Each clause corresponds to a set of 3 vertices.

G has $3m$ vertices, where m is the number of clauses. Each clause corresponds to a set of 3 vertices.

So, the clause 1 corresponds to this group, clause 2 corresponds to this group and clause, clause 3 corresponds to this group. So, the graph will have $3m$ vertices, basically m groups of vertices, and each group contains 3 vertices. So, the graph will have $3m$ vertices.

So, here, m is also 3, so, it is 9 vertices here, it has $3m$ vertices, where m is the number of clauses and each clause corresponds to a group of 3 vertices, which I have indicated here, this vertex corresponds to clause 1. Clause 1, clause 2, clause 3. So, that are the vertices and it is also labelled as such.

(Refer Slide Time: 07:18)

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

NPTEL

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

NPTEL

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

NPTEL

So, clause 1 is $x_1 \vee x_2 \vee x_3$. Clause 2 is $\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3$. Similarly, for clause 3. So, I have told the vertices. Now, how do we define the edges?

(Refer Slide Time: 07:57)

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

NPTEL

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

C has 3 variables, where each is the number of

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

C has 3 variables, where each is the number of

So, edges are very simple, we want to connect all possible vertices, but with 2 exceptions. We do not connect 2 vertices if one of the 2 cases apply. So, one is that within a group, we do not have any internal edges. So, we do not have edges like this. So, in that case, we do not put an edge. So, if you see all the edges are across groups, nothing within the group that is case 1.

(Refer Slide Time: 08:19)

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

C_1 C_2 C_3

C has 2 variables whose value is the number of

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

C_1 C_2 C_3

C has 2 variables whose value is the number of

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

C_1 C_2 C_3

C has 2 variables whose value is the number of

Second is that we do not have edges from x_1 to \bar{x}_1 and x_2 to \bar{x}_2 . So, basically for any variable x_i , we do not have edges from x_i to \bar{x}_i . In other words, x_1 and \bar{x}_1 are directly conflicting literals, x_1 and \bar{x}_1 cannot both be true. So, corresponding to that, I do not want to put an edge between these conflicting things. So, for any i , x_i and \bar{x}_i cannot be adjacent.

(Refer Slide Time: 08:52)

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

NPTEL

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

NPTEL

We will demonstrate the reduction through an example.

$$\text{Consider } \phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3).$$

C_1 has 3 variables, where n is the number of

We will demonstrate the reduction through an example.

$$\text{Consider } \phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3).$$

C_1 has 3 variables, where n is the number of

We will demonstrate the reduction through an example.

$$\text{Consider } \phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3).$$

C_1 has 3 variables, where n is the number of

So, here x_1 and \bar{x}_1 cannot be adjacent, x_2 and \bar{x}_2 cannot be adjacent. But x_2 and \bar{x}_1 can have an edge no problem, because there is no issue with that x_2 and \bar{x}_1 can also have an edge, but for the same i , x_i and \bar{x}_i cannot have an edge.

(Refer Slide Time: 09:19)

G has $3m$ vertices, where m is the number of clauses. Each clause corresponds to a set of 3 vertices.

Edges: We add edges between any two vertices, except when (1) they are from the same clause and (2) they are labelled x_i and \bar{x}_i for the same i .

The construction is straightforward given Φ , and takes only $O(m^2)$ time.

Now we need to show the following:

G has $3m$ vertices, where m is the number of clauses. Each clause corresponds to a set of 3 vertices.

Edges: We add edges between any two vertices, except when (1) they are from the same clause and (2) they are labelled x_i and \bar{x}_i for the same i .

The construction is straightforward given Φ , and takes only $O(m^2)$ time.

Now we need to show the following:

G has $3m$ vertices, where m is the number of clauses. Each clause corresponds to a set of 3 vertices.

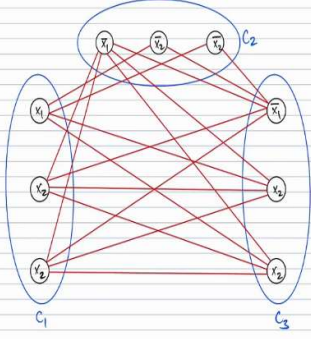

Edges: We add edges between any two vertices, except when (1) they are from the same clause and (2) they are labelled x_i and \bar{x}_i for the same i .

The construction is straightforward given Φ , and takes only $O(m^2)$ time.

Now we need to show the following:

Consider $\Phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

G has $3m$ vertices, where m is the number of clauses. Each clause corresponds to a set of 3 vertices.

So, this is the same thing that I said here, we add edges between any 2 vertices, except when they are from the same clause. And they are labelled x_i and \bar{x}_i for the same i . And everything else is here, you can just have a look everything else is here. And it is it should be evident that the construction is straightforward.

So I have $3m$ vertices. And I connect them by just doing this. So I have these groups. So I can have a for-loop, which outputs the edges, which output the adjacency matrix or something of the graph. And we can have maybe at most $(3m)^2$ edges. So, $9m^2$.

(Refer Slide Time: 10:05)

G has $3m$ vertices, where m is the number of clauses. Each clause corresponds to a set of 3 vertices.

Edges: We add edges between any two vertices, except when (1) they are from the same clause and (2) they are labelled x_i and \bar{x}_i for the same i .

The construction is straightforward given Φ , and takes only $O(m^2)$ time.

Now we need to show the following:

Φ is satisfiable $\iff G$ has m clique.

~~Φ is SAT $\iff G$ has m clique~~

So, the construction is straightforward, the running time of this construction is order m^2 . So, where order m^2 is the size of the output and that is pretty much the running time the running time is not significantly more.

(Refer Slide Time: 10:22)

Given Φ , we need to construct a CLIQUE instance $\langle G, k \rangle$ such that

$$\Phi \in 3\text{-SAT} \iff \langle G, k \rangle \in \text{CLIQUE}$$

He will demonstrate the reduction through an example.

Consider $\Phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

NPTEL

So, like in any reduction, we have to show 2 things, one is that given the 3 SAT instance, we have to produce a CLIQUE instance in polynomial time. So, that is already shown, because I said the construction is straightforward, and I explained the construction. So, given the formula we can easily produce the graph.

(Refer Slide Time: 10:52)

the tape and heads.

Def 7.29: language A is polynomial time reducible to language B , denoted $A \leq_p B$, if \exists poly time computable function f such that $\forall w \in \Sigma^*$,

$$w \in A \iff f(w) \in B$$

f is called the polynomial time reduction from A to B .

Goal: This gives me way to decide A efficiently.

- (1) Transform A to B : Compute $f(w)$
- (2) Decide B .

NPTEL

the tape and halts.

Def 7.29: language A is polynomial time reducible to language B , denoted $A \leq_p B$, if \exists poly time computable function f such that $\forall w \in \Sigma^*$,

$$w \in A \iff f(w) \in B$$

f is called the polynomial time reduction from A to B .

Goal: This gives me way to decide A efficiently.

- (1) Transform A to B : Compute $f(w)$
- (2) Decide B .

Def 7.29: language A is polynomial time reducible to language B , denoted $A \leq_p B$, if \exists poly time computable function f such that $\forall w \in \Sigma^*$,

$$w \in A \iff f(w) \in B$$

f is called the polynomial time reduction from A to B .

Goal: This gives me way to decide A efficiently.

- (1) Transform A to B : Compute $f(w)$
- (2) Decide B .

We will see that $A \leq_p B$ and $B \leq_p A \Rightarrow A \equiv_p B$.

↓

Now, the second thing to show is this thing that any member from A goes to a yes instance of B , anything from \bar{A} goes to \bar{B} or in our case, any formula that is satisfiable gives us $\langle G, K \rangle$ where G has a K clique. Any formula that is not satisfiable gives us a $\langle G, K \rangle$ where G does not have a K clique.

So, if φ is satisfiable, we get $\langle G, K \rangle$ where G with a K clique, if φ is not satisfiable we get $\langle G, K \rangle$ where G does not have K clique, this is the thing that we need to show.

(Refer Slide Time: 11:37)

vertices.

Edges: We add edges between any two vertices, except when (1) they are from the same clause and (2) they are labelled x_i and \bar{x}_i for the same i .

The construction is straightforward given ϕ , and takes only $O(n^2)$ time.

Now we need to show the following:

ϕ is satisfiable $\iff G$ has m clique

$\phi \in 3\text{-SAT} \iff \langle G, m \rangle \in \text{CLIQUE}$

$(\implies) \phi \in 3\text{-SAT} \implies \exists$ an assignment which sets each clause to true

vertices.

Edges: We add edges between any two vertices, except when (1) they are from the same clause and (2) they are labelled x_i and \bar{x}_i for the same i .

The construction is straightforward given ϕ , and takes only $O(n^2)$ time.

Now we need to show the following:

ϕ is satisfiable $\iff G$ has m clique

$\phi \in 3\text{-SAT} \iff \langle G, m \rangle \in \text{CLIQUE}$

$(\implies) \phi \in 3\text{-SAT} \implies \exists$ an assignment which sets each clause to true

So, ϕ is satisfiable if and only if G has a K clique, so our K is also going to be m . So, this is our claim ϕ is in 3 SAT, if and only if $\langle G, m \rangle$ is in CLIQUE. So, whenever ϕ is in 3 SAT, G will have an m CLIQUE, whenever ϕ is not satisfiable G will not have an m CLIQUE. So that is a claim. Let us see why this is true.

(Refer Slide Time: 12:10)

$\phi \in 3\text{-SAT} \iff \langle \phi, m \rangle \in \text{CNFQUC}$

$(\Rightarrow) \phi \in 3\text{-SAT} \Rightarrow \exists$ an assignment which sets each clause to true.

\Rightarrow Every clause has at least one true literal.

\Rightarrow Choose one true literal from each clause. These correspond to m vertices.

\Rightarrow These m vertices will be adjacent to one another.

(Since we cannot have both x_i and \bar{x}_i set to True in a satisfying

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

NPTEL

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

$x_1 = F$
 $x_2 = T$

NPTEL

So, suppose ϕ is in 3 SAT. So this formula is in 3 SAT actually, because it is a very simple formula by making x_1 true you can set you can make the first clause satisfied. And by making x_2 false, no, sorry, you have to make x_2 true to make the first and third clause satisfied. And you can make x_1 false, this is satisfiable. So, x_1 equal to false and x_2 equal to true is a satisfying assignment.

So x_2 equal to true satisfies the first and third clauses. x_1 equal to false satisfies the second clause. So we have to show that ϕ is in 3 SAT if and only if G has an m CLIQUE. So let us assume that ϕ is in 3 SAT, and then show that G has an m CLIQUE. Later, we will show the reverse direction. So, ϕ is in 3 SAT implies that there is an assignment which sets each clause to true which means every clause has 1 true literal.

(Refer Slide Time: 13:54)

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

$x_1 = F$
 $x_2 = T$

G has 3 m minterms, where m is the number of minterms F, A, D are compatible to a set d ?

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

$x_1 = F$
 $x_2 = T$

G has 3 m minterms, where m is the number of minterms F, A, D are compatible to a set d ?

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

$x_1 = F$
 $x_2 = T$

G has 3 m minterms, where m is the number of minterms F, A, D are compatible to a set d ?

And now, so let us see here. So here, every clause has 1 true literals. So here for this satisfying assignment x_2 is a true literal in the first clause, $\overline{x_1}$ is a true literal in the second clause, and let us say x_2 is the true literal in the third clause. So, the highlighted ones are the 2 literals.

And what we do is choose the same literals from the graph. So here we choose x_2 from the first clause, $\overline{x_1}$ from the second clause and x_2 from the third clause. These are the true literals and the claim is that these 3 will be adjacent. Why is that? So, in the figure, you can see that they are indeed adjacent.

But why is why are they adjacent in general? They are adjacent in general because first of all, they are in 3 clauses. So, they are not in the same group. So, we do not put edges only if 2 conditions are satisfied or only for 2 reasons. One is if they are in the same group and two is if they are of the form x_1 and $\overline{x_1}$ or x_2 or $\overline{x_2}$ and so on.

So, none of them are in the same group, because we picked each 1 from a different clause. So, the only way there will not be an edge between two of these, the only way there can be an absence of an edge between two of these is if they are of the form x_i and $\overline{x_i}$.

But then, we cannot have x_i and $\overline{x_i}$ because we pick true literals from each clause. So, if our assignment x_i was true, then x_i will be the true literal, $\overline{x_i}$ will not be true literal. So, hence, if we picked x_2 here, x_2 compliment will not be true. So, we cannot pick x_i and $\overline{x_i}$ from 2 different clauses. So that is the other way in which there may not be an edge.

So, there will be an edge between any pair of vertices here because, firstly, they are all from separate groups. And secondly, we do not have any pair x_i and $\overline{x_i}$ because if it was there, then it will be a contradiction to the way we chose these variables. So these literals were chosen since they are all true.

So, if x_i is true, $\overline{x_i}$ cannot be true, if $\overline{x_i}$ is true, then x_i cannot be true. So, both of them will not be true together. So, either for a variable x_i , the x_i was a true variable and only x_i was picked or $\overline{x_i}$ was picked, but not both. So, that means that the vertices pick from the 3 groups or from the m groups in general. So, in general, we have m clauses, all of them will be adjacent to each other, and that gives us an m CLIQUE. And here we have we have a 3 CLIQUE because m is 3.

(Refer Slide Time: 17:03)

(\Rightarrow) $\phi \in 3\text{-SAT} \Rightarrow$ \exists an assignment which sets each clause to true.

\Rightarrow Every clause has at least one true literal.

\Rightarrow Choose one true literal from each clause. These correspond to m vertices.

\Rightarrow These m vertices will be adjacent to one another.

(Since we cannot have both x_i and \bar{x}_i set to true in a satisfying assignment)

\Rightarrow Every clause has at least one true literal.

\Rightarrow Choose one true literal from each clause. These correspond to m vertices.

\Rightarrow These m vertices will be adjacent to one another.

(Since we cannot have both x_i and \bar{x}_i set to true in a satisfying assignment)

These m vertices form a clique. \therefore

$\langle k, m \rangle \in \text{CLIQUE}$.

(\Leftarrow) $\langle k, m \rangle \in \text{CLIQUE} \Rightarrow \phi$ has m clauses.

Same thing here. So, every clause has at least one true literal. And so, we choose 1 true literal from each clause and these correspond to m vertices, because there m clauses and these m vertices will be adjacent, because we cannot have both x_i and \bar{x}_i set to true. This is a key thing we cannot have both x_i and \bar{x}_i set to true. Hence, the graph has an m CLIQUE.

(Refer Slide Time: 17:31)

$(\Leftarrow) \langle G, m \rangle \in \text{CLIQUE} \Rightarrow G \text{ has } m \text{ clique.}$

\Rightarrow The clique contains exactly one
literal from each clause.

\Rightarrow We cannot have x_i & \bar{x}_i both
in the clique, for the same i .
(Since by construction, there are
no edges between them)

So we have m non-contradicting literals, one
from each clause. We can assign true to all of them.

Each clause is true $\Rightarrow \phi$ is satisfied.

$\Rightarrow \phi \in \text{3-SAT.}$

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$.

$x_1 = F$
 $x_2 = T$

G has 3 m vertices, where m is the number of

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$.

$x_1 = F$
 $x_2 = T$

G has 3 m vertices, where m is the number of

Now, the reverse direction suppose the graph has an m CLIQUE, then we have to show that the formula is satisfied. So, suppose the graph has an m CLIQUE. Now we know that there are m groups and we know that we do not have any edges within the same group these edges do not exist.

So, which means I can have at most 1 vertex in this m CLIQUE from each group, I cannot have more than 1 vertex, because if I pick 2 of these vertices, then this is not going to be a CLIQUE. So, I can have at most 1 vertex from each group, but then there are only m groups, which means I have to have 1 vertex from each group.

So, if this graph has a 3 CLIQUE, that it has to be 1 vertex from each of these 3 groups, because inside I am not putting internal edges, so we cannot have 2 from 1 group. So, it has to be distributed 111. So, G has an m CLIQUE means that each vertex in the CLIQUE comes from a distinct group, which means each group contributes exactly 1 vertex.

(Refer Slide Time: 18:54)

These m vertices form a clique. So
 $\langle G, m \rangle \in \text{CLIQUE}$.

$\langle \Leftarrow \rangle \langle G, m \rangle \in \text{CLIQUE} \Rightarrow G$ has m clique.

\Rightarrow The clique contains exactly one vertex from each clause.

\Rightarrow We cannot have x_i & \bar{x}_i both in the clique, for the same i .
(Since by construction, there are no edges between them)

So we have m non-contradicting literals, one from each clause. We can assign true to all of them.

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$.

$x_1 = F$
 $x_2 = T$

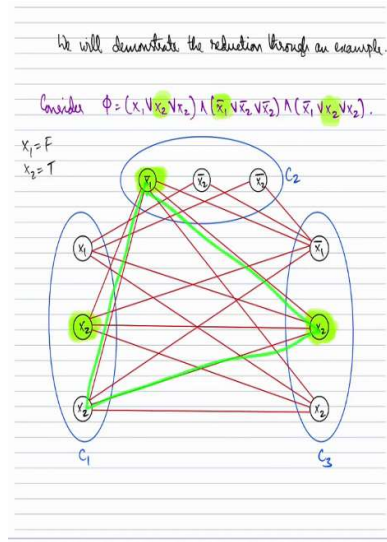

We will demonstrate the reduction through an example.

Consider $\phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (x_1 \vee x_2 \vee x_3)$.

$x_1 = F$
 $x_2 = T$

So, the CLIQUE contains exactly 1 vertex from each clause. And we know that we cannot have x_i and \bar{x}_i in the CLIQUE, because if I picked for some i , x_i and \bar{x}_i from 2 separate groups, we know there is no edge between them that is the rule that we have. So, if for any variable we picked x_i then \bar{x}_i was not picked, if any for any variable, we picked \bar{x}_i , then x_i was not picked.

So, because we did not put edges between them, so, what we have is some set of m literals. So, these m vertices that form a CLIQUE correspond to some set of m non contradicting literals. So here, if you look at the CLIQUE, so maybe another CLIQUE that we can identify is this one. But in this case, there is only 1 satisfying assignment.

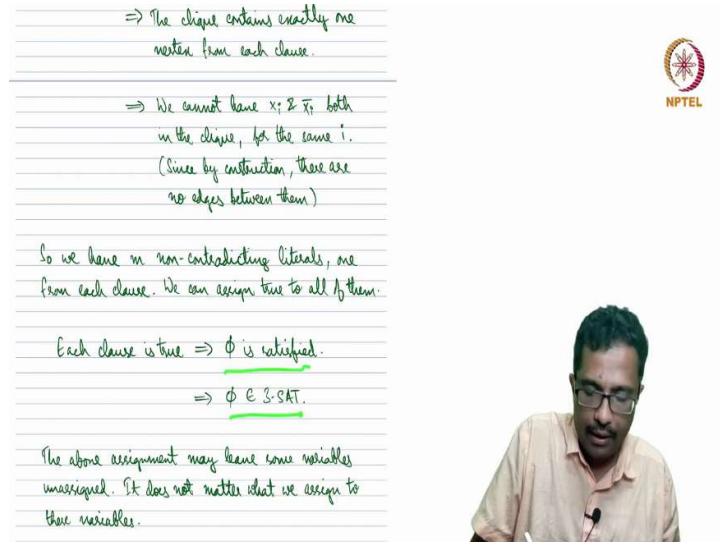

So all the clicks that you identify will be of the form \bar{x}_1, x_2, x_2 , because that is only satisfying assignment. So \bar{x}_1, x_2, x_2 . So, the thing is that we do not have x_1 and \bar{x}_1 , we only have 1 of them. And same, we do not have both x_2 and \bar{x}_2 , we only have 1 of them in the CLIQUE. So, for some variables, for some x_i we have x_i , for some x_i , we have \bar{x}_1 .

So, we have some, let us say for x_1 , x_1 is picked, for x_2 , x_2 is picked, for x_3 , let us say \bar{x}_3 is picked. Now, what we do is we set all these to be true. So, if x_i is picked, we make x_i to be true, if \bar{x}_i is picked, we make \bar{x}_i to be true. In other words, we make x_i to be false. So, we make all the selected literals to be true.

And this will be completely fine because we do not have conflicting literals, if x_i was set to true, \bar{x}_i will never have been set to true, because these 2 cannot be part of the same CLIQUE. So, we assign true to all the m non contradicting literals. And by choice we, so by the choice of the literals, we picked exactly 1 true literal from each clause or the CLIQUE contained 1

vertex from each clause, which we set to true. So, we have 1 true literal from each clause. So, each clause is satisfied.

(Refer Slide Time: 21:41)

\Rightarrow The clique contains exactly one vertex from each clause.

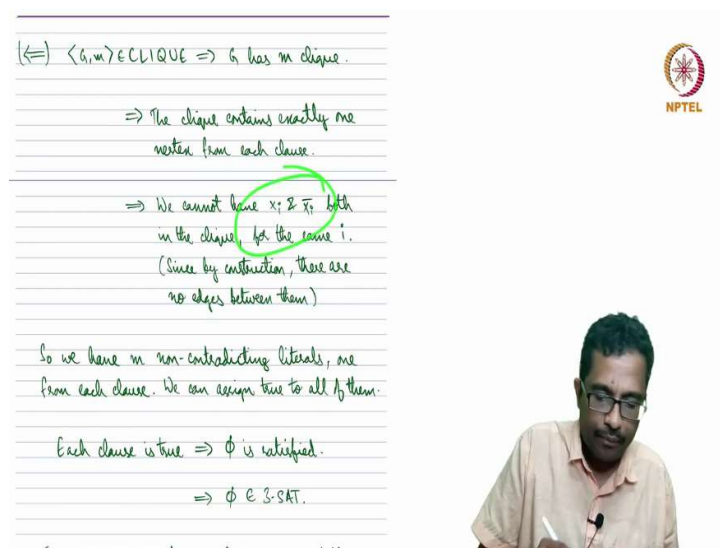

\Rightarrow We cannot have x_i & \bar{x}_i both in the clique, for the same i .
(Since by construction, there are no edges between them)

So we have m non-contradicting literals, one from each clause. We can assign true to all of them.

Each clause is true $\Rightarrow \Phi$ is satisfied.

$\Rightarrow \Phi \in 3\text{-SAT}$.

The above assignment may leave some variables unassigned. It does not matter what we assign to those variables.

$(\Leftarrow) \langle G, m \rangle \in \text{CLIQUE} \Rightarrow G$ has m clique.

\Rightarrow The clique contains exactly one vertex from each clause.

\Rightarrow We cannot have x_i & \bar{x}_i both in the clique, for the same i .
(Since by construction, there are no edges between them)

So we have m non-contradicting literals, one from each clause. We can assign true to all of them.

Each clause is true $\Rightarrow \Phi$ is satisfied.

$\Rightarrow \Phi \in 3\text{-SAT}$.

And since each clause is satisfied, that means that the formula is in 3 SAT. There is a small point. So, it is possible that the since we assigned some x_i to be true, some x_i to be false. It is possible that some other some x_j 's, or some x_k 's may not have been assigned anything, maybe the same, let us say x_1 may satisfy 2 clauses, x_2 may satisfy 3 clauses. So maybe it so happens that x_4 is never assigned by this process.

But what it means that we can assign this x_4 to true or false, it does not matter. Whatever we assign, we have already satisfied all the clauses. So in any clause that contains x_4 , there is some

other variable that has satisfied that clause. So, whatever we assign x_4 does not matter, so the unassigned variable, we assign anything, it does not really matter, but the point is that by the virtue of assigning these literals that were chosen from the CLIQUE, we have satisfied all the clauses, and hence, the formula is satisfiable.

(Refer Slide Time: 22:55)

The construction is straightforward given Φ , and takes only $O(m^2)$ time.

Now we need to show the following:

Φ is satisfiable $\Leftrightarrow G$ has an clique

$\Phi \in 3\text{-SAT} \Leftrightarrow \langle G, m \rangle \in \text{CLIQUE}$

$(\Rightarrow) \Phi \in 3\text{-SAT} \Rightarrow \exists$ an assignment which sets each clause to true.

\Rightarrow Every clause has at least one true literal.

\Rightarrow Choose one true literal from each clause. These correspond to m

Consider $\Phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

$x_1 = F$
 $x_2 = T$

G has $3m$ vertices, where m is the number of

Suppose Φ has n variables m clauses.

$\Phi = (a_1 \vee b_1 \vee c_1) \wedge (a_2 \vee b_2 \vee c_2) \wedge \dots \wedge (a_m \vee b_m \vee c_m)$

where each of a_i, b_i, c_i are a literal (x_i / \bar{x}_i).

Given Φ , we need to construct a CLIQUE instance $\langle G, k \rangle$ such that

$\Phi \in 3\text{-SAT} \Leftrightarrow \langle G, k \rangle \in \text{CLIQUE}$

We will demonstrate the reduction through an example.

Consider $\Phi = (x_1 \vee x_2 \vee x_3) \wedge (\bar{x}_1 \vee \bar{x}_2 \vee \bar{x}_3) \wedge (\bar{x}_1 \vee x_2 \vee x_3)$.

$x_1 = F$
 $x_2 = T$

Polynomial time Reductions

We had seen mapping reductions earlier. This is similar, but with a constraint on the machine that computes the reduction.

Def 7.28: $f: \Sigma^* \rightarrow \Sigma^*$ is a polynomial time computable function if there is some polynomial time DTM M that takes input w , writes $f(w)$ on the tape and halts.

Def 7.29: language A is polynomial time reducible to language B , denoted $A \leq_p B$, if \exists poly time computable function f such that $\forall w \in \Sigma^*$,

$$w \in A \iff f(w) \in B$$

f is called the polynomial time reduction from A to B .

Def 7.29: language A is polynomial time reducible to language B , denoted $A \leq_p B$, if \exists poly time computable function f such that $\forall w \in \Sigma^*$,

$$w \in A \iff f(w) \in B$$

f is called the polynomial time reduction from A to B .

Goal: This gives me way to decide A efficiently.

(1) Transform A to B : Compute $f(w)$
 (2) Decide B .

We will see that $A \leq_p B$ and $B \in P \Rightarrow A \in P$.

So, should we just recap we have to show that formula is satisfiable if and only if the constructed graph has an m CLIQUE, if the formula is satisfiable, we consider a satisfying assignment. And we pick 1 variable or 1 literal from each clause that is satisfied. And the claim is that, this forms an m CLIQUE.

Because they are from m clauses. And because it is a satisfying assignment, it will not have both x_i and \bar{x}_i for any i . So this forms m CLIQUE. So, if ϕ satisfiable G has an m CLIQUE for other direction, if G has an m CLIQUE, we know that each group or each clause has only 1 vertex cannot have more than 1 vertex, because there are no internal edges.

So, which means each group has exactly 1 vertex. And now, we just select those groups. And because we do not put edges between x_i and \bar{x}_i , we know that all these selected literals or all

the selected vertices or the literals that correspond to these vertices, they are not conflicting, and we can set all of them to be true.

So, suppose, $x_1, x_2, \overline{x_3}, \overline{x_4}$ complement are picked, then we set x_1 and x_2 to be true and x_3 and x_4 to be false. So now that translate to at least 1 satisfying literal in each clause, so each clause is satisfied, hence, the formula is satisfied. So there may be variables that we do not set either way, but we can set in any way it does not matter.

So, that completes the proof of correctness of this reduction. So, the reduction is straightforward, the proof of correctness is a bit more involved. So we saw that, given a 3 SAT instance ϕ , we can construct a graph and m says that if ϕ is in 3 SAT if and only if G has an m CLIQUE.

And prior to that we defined polynomial time reductions. So, it is a transformation from an A instance to B instance such that every yes instance is mapped to a yes instance and every no instance is mapped to a no instance. And further the computation of this reduction function should be in polynomial time. So, we had all these results.

(Refer Slide Time: 25:33)

We can get easy reduction from SAT to 3-SAT if we don't impose restrictions on the power of the reduction function.

Theorem 7.31: $A \leq_P B$ and $B \in P \Rightarrow A \in P$.

Proof: Suppose M is the polynomial time decider for B . We can construct a decider for A as follows:
Assume f is the poly time reduction.
On input w :
(1) Compute $f(w)$. $\rightarrow n^{k_1}$
(2) Run M on $f(w)$. $\left. \begin{array}{l} \text{Accept iff } M \text{ accepts } f(w). \end{array} \right\} n^{k_1 k_2}$

Correctness: Straightforward.

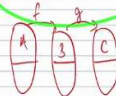

Time: Both steps (1) and (2) are poly time.

Suppose $f(w)$ takes n^{k_1} time ($n=|w|$)
Suppose M runs in $|f(w)|^{k_2}$ time.
Since time taken for the reduction is n^{k_1} , we have $|f(w)| \leq n^{k_1}$.
 M takes $(n^{k_1})^{k_2}$ time = $n^{k_1 k_2}$.
So the A -decider takes $n^{k_1 k_2}$ time.

Other results

(1) $A \leq_P B$ and $B \in P \Rightarrow A \in P$
(2) $A \leq_P B$ and $A \in P \Rightarrow B \in P$
(3) $A \leq_P B$ and $B \leq_P C \Rightarrow A \leq_P C$
(4) $A \leq_P B \Rightarrow \bar{A} \leq_P \bar{B}$

$g \cdot f$ gives a reduction from A to C .

So we have m non-contradicting literals, one from each clause. We can assign true to all of them.

Each clause is true $\Rightarrow \Phi$ is satisfied.
 $\Rightarrow \Phi \in 3\text{-SAT}$.

The above assignment may leave some variables unassigned. It does not matter what we assign to these variables.

Note: The above reduction uses tools/construction to convert one problem into another. These tools are called gadgets.

A reduces to B and B is in P implies A is in P, A reduces to B in A not in P implies B not in P and all of this and finally, that kind of concludes the lecture 48. And I just want to make 1 small remark before concluding. So, the construction that we had for showing that satisfiability reduces to CLIQUE. So, this was there is a certain pattern or structure to this.

So, many times when we are reducing 1 problem to another, sometimes we need to make use of some of these types of constructions. And these constructions are like commonly called as gadgets. So, these tools for making the reduction, so sometimes they are called gadgets, just to familiarise with the term. We will not be seeing that many reductions in this course, maybe like 4 or 5 reductions, maybe in the next week.

But if you look at a book on reductions, and if it uses the word gadgets, I am just saying this so that you can be familiar with this usage. So that is it. So, we saw reductions, we saw the definition. We saw 1 example that 3 SAT reduces to CLIQUE. And that is all for lecture number 48. And next we will see NP completeness in the coming lectures. So, see you in lecture 49. Thank you.
