Hello, welcome back to this series of lectures on Numerical Optimization. In the last class, we started looking at constrained optimization.

(Refer Slide Time: 00:36)

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

Let  $X = \{\mathbf{x} \in \mathbb{R}^n : h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l\}$ . For any  $\mathbf{x} \in X$ ,  
 $\tilde{\mathcal{F}}(\mathbf{x}) \triangleq \{\mathbf{d} : \nabla h_j(\mathbf{x})^T \mathbf{d} < 0, \quad j \in \mathcal{A}(\mathbf{x})\} \subseteq \mathcal{F}(\mathbf{x})$  and  
 $\tilde{\mathcal{D}}(\mathbf{x}) \triangleq \{\mathbf{d} : \nabla f(\mathbf{x})^T \mathbf{d} < 0\} \subseteq \mathcal{D}_0(\mathbf{x})$ .

NPTEL  
Shirish Shevade, Numerical Optimization

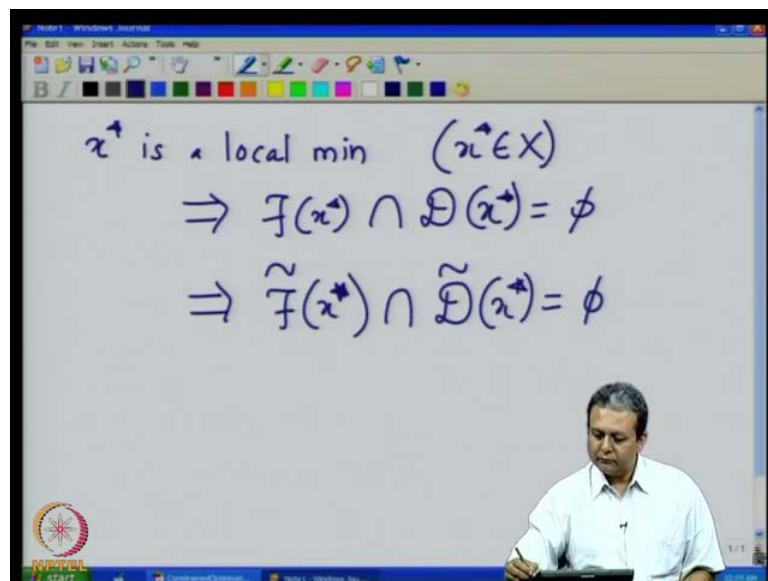

In the problem that we are interested in solving is a minimize  $f$  of  $\mathbf{x}$  subject to the constrained that  $h_j(\mathbf{x}) \leq 0$ ; there are  $l$  such inequality constraints. For the time being, we are not considering equality constraints, but we will consider those constraints as well sometime later. And we define the constrained set  $X$  to be the set of all vectors in  $\mathbb{R}^n$  such that  $h_j(\mathbf{x}) \leq 0$  for all  $j$  is going from 1 to  $l$ .

And then, we define a two sets, one set is the  $\tilde{\mathcal{F}}(\mathbf{x})$  set and that is corresponding to the set of active constraints, at the current point  $\mathbf{x}$  and the set of active constraints is the set of all inequality constraints, which are binding at a given point  $\mathbf{x}$  or in other words those are the constraints which are satisfied with equality at a given point  $\mathbf{x}$ . So, we collect all those active constraints at a given point  $\mathbf{x}$  and call that set as  $\mathcal{A}(\mathbf{x})$ . And

the set  $F_{\tilde{x}}$  defined as the set of all directions  $d$  the non zero directions such that they make an obtuse angle with the gradients of the active constraints.

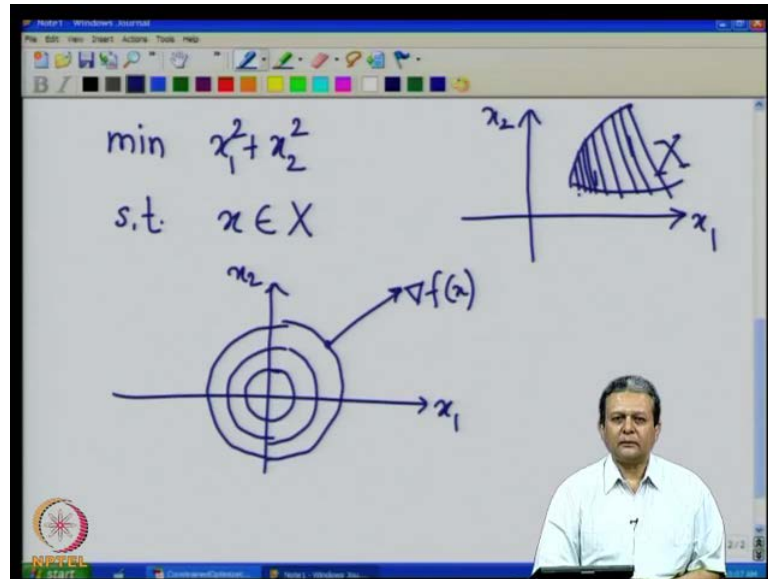

And we also showed in the last class that  $F_{\tilde{x}}$  is a subset of  $f_x$ ,  $f_x$  is a set of all feasible directions the non zero feasible directions. And we also define the set  $D_{\tilde{x}}$  to be the set where the set of all directions  $d$  such that they make an obtuse angle with the gradient of  $f$  at given  $x$ ; and we have already seen that this is also a subset of  $D_x$ .

(Refer Slide Time: 02:50)

Now, we have seen that  $x^*$  is a local min, that implies that  $f_{x^*}$  remember that  $x^*$  belongs to the set of feasible points. So,  $f_{x^*} \cap D_{x^*}$  is a null set and we saw that  $f_{\tilde{x}^*}$  is a subset of  $f_{x^*}$  and  $D_{\tilde{x}^*}$  is a subset of  $D_{x^*}$  and therefore, we can write this as  $f_{\tilde{x}^*} \cap D_{\tilde{x}^*}$  is a null set. The reason for doing or the reason for using  $f_{\tilde{x}}$  and  $D_{\tilde{x}}$  is that they can be expressed using the gradients of the objective function and the active constraints. And that can be used to derive algebraic conditions, which can be used as necessary conditions for  $x^*$  to be a local min.

(Refer Slide Time: 04:19)

So, so, let us consider a simple problem suppose that we want to minimize  $x_1$  square plus  $x_2$  square subject to  $x$  belongs to  $X$ , remember that this  $x$  is a vector having two component  $x_1$  and  $x_2$  and let us define our constraints set as  $X$ . So, this is our constraint set  $X$  now, if we look at the contours of the objective functions they are the circular contours. So, in other words the objective function contours would be something like this. So, you have two coordinates  $x_1$  and  $x_2$  and then this contours are circles of different radii.

So, these are the objective function contours and as we see that at a given point  $x$  since, the function is differentiable we can take the gradient. So, gradient  $\nabla f(x)$  will be in this direction and as we move in the direction towards the negative of the gradient we decrease the objective function. So, suppose we want to solve this constraint problem.

(Refer Slide Time: 06:15)

Now, let us look at the let us take the constraint set but, we have seen earlier and let us take a feasible point. So, let us choose some point it is call this as  $x_A$  now, this  $x_A$  lies in the interior of the set and none of the constraints are active. So, if you look at the feasible directions, the feasible directions at  $x_A$  is  $\mathbb{R}^2$ .

So, now let us look at the, set of descent directions that  $\mathbb{R}^2$ . So, so if you look at the objective function. So, if you look at the, suppose this is the point  $x_A$  now, we draw the objective function which passes through this point. So, this is the objective function which passes through this point and we will see that the gradient at this point is pointing in this direction. And therefore, if you want to find out the set of descent directions or in other words we are interested in finding  $\tilde{D}(x_A)$ .

And that  $\tilde{D}(x_A)$  will be something like this that we have the two directions and then, we take a normal to this gradient  $\nabla f$  of  $x_A$ . So, this is the tangent plane at  $x_A$ , so we have shifted  $x_A$  to the origin and then, we are looking at those directions which make an obtuse angle with gradient of  $\nabla f$  of  $x_A$ . So, so this is the set which will be  $\tilde{D}(x_A)$ , note that the gradient  $\nabla f$  of  $x_A$  is pointing in this direction and the set of all directions which make an obtuse angle with gradient of  $\nabla f$  of  $x_A$ .

That that set is  $\tilde{D}(x_A)$  and we will see that, this set is non-empty so; that means, that if we are at  $x_A$  it is possible to decrease the objective function further. So, that we we can minimize the objective function. Now, let us take the same example.

(Refer Slide Time: 09:55)

So, let us take a point  $x_B$ . Now, if you take this point  $x_B$  let us look at the the, set of active constraints; so this constraint as well as this constraint, this active here. So, let us take the gradients of this constraints and they will be and the gradient with respect to this; so if we take this gradients and then use them.

So, this region is now, the region  $\tilde{f}(x_B)$  remember that this was our set constraint set  $X$  and what we did was we considered or the active constraints at  $x_B$ , which are these two constraints and took tangent planes. And then took their the intersection of the respective sets and that terms out to be  $\tilde{f}(x_B)$ . Now, if we consider the objective function at  $x_1$   $x$  at  $x_B$ . So, this is going to be the point  $x_B$  then the objective function here, would be this and this is going to be the gradient of  $f$  at  $x_B$ .

So, let us take the gradient of  $f$  at  $x_B$  and then, if we take a tangent plane at  $x_B$ . So, the tangent plane will be, and then this will be  $\tilde{D}(x_B)$ . So, you will see that, in this case  $\tilde{f}(x_B)$  and  $\tilde{D}(x_B)$  does not have any intersection because,  $\tilde{D}(x_B)$  is this cone, open cone and  $\tilde{f}(x_B)$  is another open cone and they do not have any intersection. So, in this case it turns out that  $x_B$  is indeed the, global minimum of this problem on the other hand if we look at the previous case.

(Refer Slide Time: 13:47)

We will see that the  $\tilde{D}(x_A)$  is non-empty. Since,  $f(A)$  is  $\mathbb{R}^2$  the entire  $\mathbb{R}^2$  plane  $\tilde{D}(x_A)$  is a non-empty set so; that means, there exist descent directions at  $x_A$ . So, that we can if you move along the descent direction, we can always decrease the objective function.

(Refer Slide Time: 14:19)

And that is not possible, if we look at  $x_B$  at  $x_B$  the  $\tilde{D}(x_B)$  and  $f^{-1}(x_B)$  have a non-empty intersection and therefore,  $x_B$  turns out to be, in this case global minimum of the problem.

(Refer Slide Time: 14:56)

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

Let  $X = \{\mathbf{x} \in \mathbb{R}^n : h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l\}$ . For any  $\mathbf{x} \in X$ ,  
 $\tilde{\mathcal{F}}(\mathbf{x}) \triangleq \{\mathbf{d} : \nabla h_j(\mathbf{x})^T \mathbf{d} < 0, \quad j \in \mathcal{A}(\mathbf{x})\} \subseteq \mathcal{F}(\mathbf{x})$  and  
 $\tilde{\mathcal{D}}(\mathbf{x}) \triangleq \{\mathbf{d} : \nabla f(\mathbf{x})^T \mathbf{d} < 0\} \subseteq \mathcal{D}(\mathbf{x})$ .

$$\begin{aligned} \mathbf{x}^* \in X \text{ is a local minimum} &\Rightarrow \mathcal{F}(\mathbf{x}^*) \cap \mathcal{D}(\mathbf{x}^*) = \phi \\ &\Rightarrow \tilde{\mathcal{F}}(\mathbf{x}^*) \cap \tilde{\mathcal{D}}(\mathbf{x}^*) = \phi \end{aligned}$$

**$\mathbf{x}^* \in X$  is a local minimum  $\Rightarrow \tilde{\mathcal{F}}(\mathbf{x}^*) \cap \tilde{\mathcal{D}}(\mathbf{x}^*) = \phi$**

- This is only a necessary condition for a local minimum
- Utility of this condition depends on the constraint representation
- Cannot be directly used for equality constrained problems

Shreshth Sharma - Numerical Optimization

So, so if  $\mathbf{x}^*$  belong to  $X$  is a local minimum then that implies that  $\mathcal{F}(\mathbf{x}^*) \cap \mathcal{D}(\mathbf{x}^*)$  is null set and since, this sets are cannot be written algebraically we wanted to use some sets, which can be represented algebraically. And therefore, we defined  $\tilde{\mathcal{F}}$  and  $\tilde{\mathcal{D}}$  and therefore, the intersection of, at a local minimum  $\mathbf{x}^*$  the intersection of  $\tilde{\mathcal{F}}(\mathbf{x}^*)$  and  $\tilde{\mathcal{D}}(\mathbf{x}^*)$  is a null set. So, we have this important result and note that this is only a necessary condition for a local minimum.

For example, if at a particular point the gradient of a function is 0 then; that means, that at that particular  $\mathbf{x}^*$  gradient  $\nabla f(\mathbf{x}^*)$  is 0. And then therefore, this set becomes a null set and this condition is automatically satisfied, but that does not mean that  $\mathbf{x}^*$  is a local minimum for a constraint problem. We also saw that the utility of this condition depends of how do we represent the constraints set. So, in the last class we considered one example, where the same constraint set if it is represented using two different waves.

Then in one case, we got  $\tilde{\mathcal{F}}(\mathbf{x}^*)$  to be a null set and in the other case we got  $\tilde{\mathcal{F}}(\mathbf{x}^*)$  not to be a null set. So, once any of this sets become empty, the intersection become automatically empty sets. So, we have to avoid such cases and we also saw that, this condition cannot be directly used for the equality constraint problems.

(Refer Slide Time: 16:53)

The whiteboard shows the following mathematical steps:

$$\begin{aligned} \min f(x) \\ \text{s.t. } e(x) = 0 \end{aligned} \quad \rightarrow \quad \begin{aligned} \min f(x) \\ \text{s.t. } e(x) \geq 0 \\ e(x) \leq 0 \end{aligned}$$

---

$$\tilde{F}(x) = \left\{ d: \begin{aligned} \nabla e(x)^T d < 0, \\ -\nabla e(x)^T d < 0 \end{aligned} \right\}$$

$$= \phi$$

Below this, a downward arrow indicates the next step:

$$\begin{aligned} \min f(x) \\ \text{s.t. } -e(x) \leq 0 \\ e(x) \leq 0 \end{aligned}$$

So, if we have a problem minimize  $f(x)$  subject to  $e(x) = 0$  this is an equality constraint problem, let us assume that we have only one equality constraint. So, we can write this problem as minimize  $f(x)$  subject to  $e(x) \geq 0$  and  $e(x) \leq 0$ ; or in other words, we can write this in our usual form minimize  $f(x)$  subject to  $-e(x) \leq 0$  and  $e(x) \leq 0$ . Now, if you look at this constraint and then write  $\tilde{F}(x)$  to be noted that this is the equality constraint.

So, both this constraint should be active at any given point  $x$ . So, set of all these such that  $\nabla e(x)^T d < 0$  and  $-\nabla e(x)^T d < 0$ . So, this corresponds to the second constraint and then this condition  $-\nabla e(x)^T d < 0$  corresponds to the first constraint. So, you will see that, this set is always a null set because, we cannot find out direction  $d$  where which is making obtuse angle with  $\nabla e(x)$  as well as negative of the gradient of  $e(x)$ .

So,  $\tilde{F}(x)$  always becomes a null set and therefore, this condition, the condition that we derived earlier that  $x^*$  is a local minimum implies that  $\tilde{F}(x^*) \cap \tilde{B}(x^*)$  is null set, that condition is trivially satisfied for the equality constraint problem.

(Refer Slide Time: 19:40)

$$\begin{aligned} & \min && f(\mathbf{x}) \\ & \text{s.t.} && h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & && \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

Let  $X = \{\mathbf{x} \in \mathbb{R}^n : h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l\}$

$\mathbf{x}^* \in X$  is a local minimum

$$\Rightarrow \tilde{\mathcal{F}}(\mathbf{x}^*) \cap \tilde{\mathcal{D}}(\mathbf{x}^*) = \emptyset$$

$$\Rightarrow \{d : \nabla h_j(\mathbf{x}^*)^T d < 0, \quad j \in \mathcal{A}(\mathbf{x}^*)\} \cap \{d : \nabla f(\mathbf{x}^*)^T d < 0\} = \emptyset$$

Let  $A = \begin{pmatrix} \nabla f(\mathbf{x}^*)^T \\ \dots \\ \nabla h_j(\mathbf{x}^*)^T, \quad j \in \mathcal{A}(\mathbf{x}^*) \\ \dots \end{pmatrix}_{(1+|\mathcal{A}(\mathbf{x}^*)|) \times n}$

$\therefore \mathbf{x}^* \in X$  is a local minimum  $\Rightarrow \{d : Ad < 0\} = \emptyset$

Shreshth Sharma, Numerical Optimization

So, now let us look at this problem and again we define constraint set  $x$  in this way and  $x$  star is a local minimum which implies that this holds. And let us rewrite, those conditions in the form of the gradients of the constraints and the objective functions, note that we are always working with the active constraints at any point of time. So, at  $x$  star we collect all the active constraints and find this set gradient  $h_j x$  start transpose  $d$  less than 0 and intersection of that with the set, where set of all directions, which make an obtuse angle with gradient  $f x$  star and  $x$  star is a local min implies that this intersection is empty.

Now, can we write this conditions in a more compact form. So, for that purpose, let us define a matrix  $A$ , whose one row is the transpose of the gradient of  $f$  at  $x$  star and the remaining rows are the the gradient vectors, transposed and put in the form of different rows of the matrix  $A$ . Remember that, this matrix  $A$  depends on a  $x$  star, but just for notational convenience, we have drop the dependents on  $x$  star we have not written that here. Now, this matrix if you look at the number of rows.

So, there is a row corresponding to the gradient of the objective function and there are, rows corresponding to the set of active constraints. So, the number of rows will be 1 plus cardinality of the set  $\mathcal{A} x$  star and since, these are gradient vectors in  $n$ -dimensional space the number of columns will be  $n$ . So, if we define this matrix  $A$  like this, then we can say that  $x$  star is a local min implies that the set of all directions  $d$  says that  $Ad$  less than 0 is

a null set. I again repeat that the  $A$  is always depends on  $x^*$ , but to avoid notational later, we have not indicated it here. So, this is the compact way of representing this constraints and slowly, we will move to the algebraic conditions which are necessary, for  $x^*$  to be a local minimum.

(Refer Slide Time: 22:10)

**Farkas' Lemma**  
 Let  $A \in \mathbb{R}^{m \times n}$  and  $c \in \mathbb{R}^n$ . Then, exactly one of the following two systems has a solution:  
 (I)  $Ax \leq 0, c^T x > 0$  for some  $x \in \mathbb{R}^n$   
 (II)  $A^T y = c, y \geq 0$  for some  $y \in \mathbb{R}^m$ .

**Corollary**  
 Let  $A \in \mathbb{R}^{m \times n}$ . Then exactly one of the following systems has a solution:  
 (I)  $Ax < 0$  for some  $x \in \mathbb{R}^n$   
 (II)  $A^T y = 0, y \geq 0$  for some nonzero  $y \in \mathbb{R}^m$ .

$x^* \in X$  is a local minimum  $\Rightarrow \{d : Ad < 0\} = \emptyset \Rightarrow$   
 $\exists \lambda_0 \geq 0$  and  $\lambda_j \geq 0, j \in \mathcal{A}(x^*)$  (not all  $\lambda$ 's 0), such that

$$\lambda_0 \nabla f(x^*) + \sum_{j \in \mathcal{A}(x^*)} \lambda_j \nabla h_j(x^*) = 0.$$

MPTCL Shrish Shrivastava Numerical Optimization

Now, to write those are algebraic conditions, we will need Farkas' lemma which we studied when we, discussed about convex sets and convex functions. So, let us recall Farkas' lemma. So, if we have matrix  $A$  which is  $m$  by  $n$  matrix of real numbers and a vectors see which is a  $n$ -dimensional vector, then exactly one of the following systems has a solution.

So, either we have  $x$  less than or equal to 0 and  $c$  transpose  $x$  greater than 0; that means, that one can find  $x$ , which makes an obtuse angle with, which makes an acute angle with  $c$  and obtuse angle with I am not an not an acute angle with the rows of the matrix  $A$  or there exist some  $y$ , which is which satisfied this condition that a transpose  $y$  is equal to  $c$  and  $y$  greater than or equal to 0. So, either of this systems, as a solution and what is important for us is a corollary of Farka's lemma that we discussed earlier and also proved.

So, let us look at this corollary, so we have a  $m$  by  $n$  matrix  $A$  and then the corollary says that exactly one of the following systems, as a solution. So, either we have  $Ax$  less than 0 or there exist some non-zero  $y$  such that such that  $A$  transpose  $y$  is 0 and  $y$  greater than

or equal to 0. So that means, there exist, some non-negative vector  $y$ , which is not 0 vector; that means, not all the components  $y$  or 0 at a kind of time and  $A^T y$  is 0.

So, either of this two systems has a solution. Now, you will see that, if the rows of the matrix  $A$  are linearly independent, then  $A^T y = 0$  will happen only in the trivial case where  $y = 0$  and therefore. So, the system may not have a solution, but then, that will be some  $x$  which is in the  $n$ -dimensional space such that  $Ax < 0$ . So, now let us use this corollary, to write the algebraic condition for a local minimum.

So, we have  $X^*$  is a local minimum implies that the set of all directions  $d$  such that  $A^T d < 0$  is a null set and we use this corollary. So, the  $A^T d < 0$  is similar to this system one and if this is a null set then system two has a solution. So that means, that there exist some  $\lambda_0$ , which is non-negative and  $\lambda_j$ , which is also non-negative, where  $j$  belongs to the set of active constraints at  $x^*$  and remember that, there is a non-zero  $y$ . So, we have these  $\lambda$ s, which are all non-zero, not all  $\lambda$ s are 0.

So, such that this condition is satisfied. So, this condition is same as the system two which is written here where  $y$ 's are replaced by  $\lambda$ s and  $A$  is the matrix, which is written using or which is obtained using gradient  $f(x^*)$  and gradient  $h_j(x^*)$ , where  $j$  belongs to  $A(x^*)$ . So, the system one has no solution, means that system two has a solution and therefore, there exist some  $\lambda$ s not all  $\lambda$ s are 0. And remember that, there is a  $\lambda_0$  associated with gradient of  $f(x^*)$  and  $\lambda_j$  associated with the set of active constraints  $h_j(x^*)$ .

So, so in this case we are able to write the necessary condition for local minimum in the form of an algebraic condition which uses, gradient vectors of the objective function and gradient vectors of the active constraints.

(Refer Slide Time: 26:53)

$\mathbf{x}^* \in X$  is a local minimum  $\Rightarrow \{\mathbf{d} : \mathbf{A}\mathbf{d} < 0\} = \phi \Rightarrow$

$\exists \lambda_0 \geq 0$  and  $\lambda_j \geq 0, j \in \mathcal{A}(\mathbf{x}^*)$  (not all  $\lambda$ 's 0), such that

$$\lambda_0 \nabla f(\mathbf{x}^*) + \sum_{j \in \mathcal{A}(\mathbf{x}^*)} \lambda_j \nabla h_j(\mathbf{x}^*) = \mathbf{0}.$$

- Easy to satisfy these conditions if  $\nabla h_j(\mathbf{x}^*) = \mathbf{0}$  for some  $j \in \mathcal{A}(\mathbf{x}^*)$  or  $\nabla f(\mathbf{x}^*) = \mathbf{0}$

 Nitish Srivastava - Numerical Optimization

Now, if you look at this condition, it is easy to satisfy this condition, when suppose gradient  $\nabla f(\mathbf{x}^*) = \mathbf{0}$ . So, in that case what we can do is that, we can set  $\lambda_0$  to any positive value and set the remaining lambdas to 0 and this condition get satisfied. Also if any of the gradient  $\nabla h_j(\mathbf{x}^*) = \mathbf{0}$  then, we can set all the remaining lambdas to 0 except that particular lambda which can be set to a positive value. So, this conditions becomes trivially satisfied under those special conditions.

Now, as I mentioned earlier that  $\mathbf{x}^*$  is local minimum implies that  $\nabla f(\mathbf{x}^*) \in \mathcal{D}(\mathbf{x}^*)$  intersection  $\mathcal{D}(\mathbf{x}^*)$  is a null set. Now, the  $\mathcal{D}(\mathbf{x}^*)$  is a null set, that condition suppose if it is satisfied for given set of active constraints, then what happens is that  $\nabla f(\mathbf{x}^*) \in \mathcal{D}(\mathbf{x}^*)$  intersection  $\mathcal{D}(\mathbf{x}^*)$  is automatically a null set. And therefore, we would not be considering the objective function at a point  $\mathbf{x}^*$  there, because object regardless of what the objective function value is that condition is always satisfied because,  $\mathcal{D}(\mathbf{x}^*)$  is always is if it a null set.

And somehow to we have avoid  $\mathcal{D}(\mathbf{x}^*)$  to be a null set. So, one way of ensuring the  $\mathcal{D}(\mathbf{x}^*)$  is not a null set is that let us assume that this gradient  $\nabla h_j(\mathbf{x}^*)$ , where  $j$  belongs to the set of all active constraints, they are linearly independent. So, this quantity can become 0 only in the trivial case, and in that case the  $\lambda_0$  becomes greater than 0 because, what we want is that not all lambdas are 0.

So, if we ensure that the gradient  $\nabla h_j(x^*)$  for  $j \in \mathcal{A}(x^*)$  are linearly independent then the only way this combination can become 0 is by setting all  $\lambda_j$  to be 0. And in that case  $\lambda_0$  cannot remain 0 and therefore, we can ensure that, the set  $\tilde{D}$  at  $x^*$ , which corresponds to the constraint set, will not be an empty set because, if we look at this.

(Refer Slide Time: 29:57)

**Farkas' Lemma**  
 Let  $A \in \mathbb{R}^{m \times n}$  and  $c \in \mathbb{R}^n$ . Then, exactly one of the following two systems has a solution:  
 (I)  $Ax \leq 0, c^T x > 0$  for some  $x \in \mathbb{R}^n$   
 (II)  $A^T y = c, y \geq 0$  for some  $y \in \mathbb{R}^m$ .

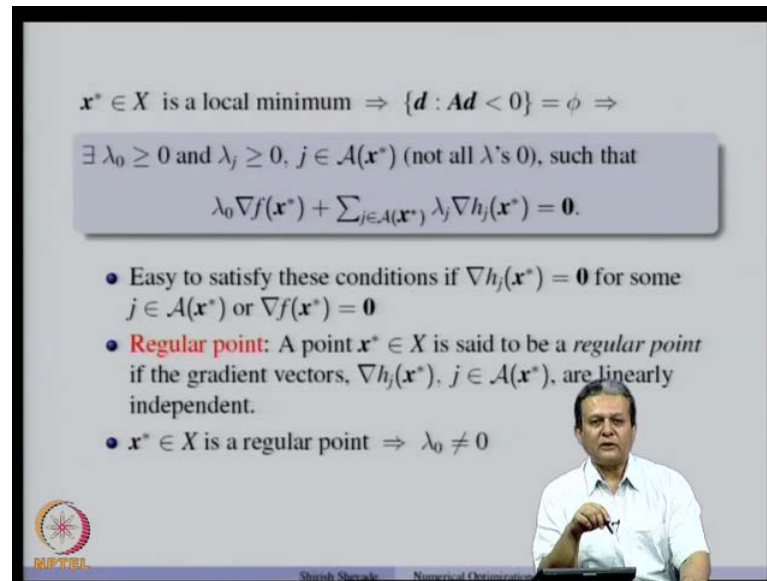

**Corollary**  
 Let  $A \in \mathbb{R}^{m \times n}$ . Then exactly one of the following systems has a solution:  
 (I)  $Ax <_0 0$  for some  $x \in \mathbb{R}^n$   
 (II)  $A^T y = 0, y \geq 0$  for some nonzero  $y \in \mathbb{R}^m$ .

$x^* \in X$  is a local minimum  $\Rightarrow \{d : Ad < 0\} = \emptyset$   
 $\exists \lambda_0 \geq 0$  and  $\lambda_j \geq 0, j \in \mathcal{A}(x^*)$  (not all  $\lambda$ 's 0), s.t.  
 $\lambda_0 \nabla f(x^*) + \sum_{j \in \mathcal{A}(x^*)} \lambda_j \nabla h_j(x^*) = 0$

NPTEL  
 Srinivasa Sankar, Numerical Optimization

So, if there exist only a combination where all  $y$ 's are 0 then this system does not have a solution; that means, that  $Ax$  is less than 0 as a solution. So, if you just consider the rows of the matrix  $A$  corresponding to the active constraints and apply this corollary you will see that, if the gradients of the active constraints are linearly dependent, then the set  $\tilde{D}$  at  $x^*$  will not be an empty set and therefore, we can avoid the trivial cases.

(Refer Slide Time: 30:38)

$\mathbf{x}^* \in X$  is a local minimum  $\Rightarrow \{\mathbf{d} : \mathbf{A}\mathbf{d} < 0\} = \phi \Rightarrow$

$\exists \lambda_0 \geq 0$  and  $\lambda_j \geq 0, j \in \mathcal{A}(\mathbf{x}^*)$  (not all  $\lambda$ 's 0), such that

$$\lambda_0 \nabla f(\mathbf{x}^*) + \sum_{j \in \mathcal{A}(\mathbf{x}^*)} \lambda_j \nabla h_j(\mathbf{x}^*) = \mathbf{0}.$$

- Easy to satisfy these conditions if  $\nabla h_j(\mathbf{x}^*) = \mathbf{0}$  for some  $j \in \mathcal{A}(\mathbf{x}^*)$  or  $\nabla f(\mathbf{x}^*) = \mathbf{0}$
- **Regular point:** A point  $\mathbf{x}^* \in X$  is said to be a *regular point* if the gradient vectors,  $\nabla h_j(\mathbf{x}^*), j \in \mathcal{A}(\mathbf{x}^*)$ , are linearly independent.
- $\mathbf{x}^* \in X$  is a regular point  $\Rightarrow \lambda_0 \neq 0$

And that is done by, using this assumption that  $\mathbf{x}^*$  is a regular point. So,  $\mathbf{x}^*$  is the regular point, if the if the gradient vectors of the active constraints are linearly independent. So, this will guarantee that  $\lambda_0$  is greater than 0 and therefore, we do depend on the objective function. Because otherwise if you do not ensure that then what will happen is that  $\{\mathbf{d} : \mathbf{A}\mathbf{d} < 0\}$  will become a null set and  $\{\mathbf{d} : \mathbf{A}\mathbf{d} < 0\} \cap X$  will be automatically a null set.

And; that means, that we are not giving importance to the objective function and that should not be the case. So, we are looking for those conditions under which, if you look at certain points, which are regular and satisfy certain conditions those are a possible candidates for a local minimum. So, as I mentioned earlier that, if it is a regular point then  $\lambda_0$  is certainly greater than 0 it cannot be equal to 0, because since this constraints are independent. The only way this quantity can become 0 is  $\lambda_j$  equal to 0 and under those are circumstances  $\lambda_0$  cannot be equal to 0, because according to the theorem this one, not all  $\lambda$ 's are 0.

So, what we do is that now, we can write this condition only with respect to the active constraints. Now, what happens to the constraints, which are inactive now, we can safely assume that the  $\lambda$ 's corresponding to those constraints are 0.

(Refer Slide Time: 32:39)

Letting  $\lambda_j = 0 \forall j \notin A(\mathbf{x}^*)$ , we get the following conditions:

$$\lambda_0 \nabla f(\mathbf{x}^*) + \sum_{j=1}^l \lambda_j \nabla h_j(\mathbf{x}^*) = \mathbf{0}$$
$$\lambda_j h_j(\mathbf{x}^*) = 0 \forall j = 1, \dots, l$$
$$\lambda_j \geq 0 \forall j = 0, \dots, l$$
$$(\lambda_0, \boldsymbol{\lambda}) \neq_{\neq} (\mathbf{0}, \mathbf{0})$$

where  $\boldsymbol{\lambda}^T = (\lambda_0, \dots, \lambda_l)$ .

So, let us would those lambdas to 0 and what we get is this condition  $\lambda_0 \nabla f(\mathbf{x}^*) + \sum_{j=1}^l \lambda_j \nabla h_j(\mathbf{x}^*) = \mathbf{0}$ . Now, remember that we have introduced this. So, all those constraints which are inactive for them  $h_j(\mathbf{x}^*) < 0$  and if you multiply  $\lambda_j$  by  $h_j(\mathbf{x}^*)$  then that becomes 0. So, for active constraint  $h_j(\mathbf{x}^*) = 0$  is always 0. So this condition is satisfied, for inactive constraints  $h_j(\mathbf{x}^*) < 0$ , but by setting  $\lambda_j$  corresponding  $\lambda_j$  is to 0 this condition is satisfied.

And  $\lambda_j$ 's are greater than or equal to 0 that that is as per the theorem or corollary of Karush's lemma that we saw earlier and not all lambdas are 0. So, the  $\lambda_0$  and  $\boldsymbol{\lambda}$ , this should be  $\lambda_0$  and  $\boldsymbol{\lambda}$  which is a vector containing  $\lambda_1$  to  $\lambda_l$ . So, these are all non-zero.

(Refer Slide Time: 33:57)

Consider the problem:

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

Assume  $\mathbf{x}^* \in X$  to be a regular point.  
 $\mathbf{x}^*$  is a local minimum  $\Rightarrow \exists \lambda_j^*, j = 1, \dots, l$  such that

$$\begin{aligned} \nabla f(\mathbf{x}^*) + \sum_{j=1}^l \lambda_j^* \nabla h_j(\mathbf{x}^*) &= \mathbf{0} \\ \lambda_j^* h_j(\mathbf{x}^*) &= 0 \quad \forall j = 1, \dots, l \\ \lambda_j^* &\geq 0 \quad \forall j = 1, \dots, l \end{aligned}$$

Shrish Shrivastava Numerical Optimization

Now, let us consider the problem, where we want to minimize the same objective function  $f(\mathbf{x})$ , subject to these constraints and now, one assumption that we make is that  $\mathbf{x}^*$  is a regular point. That means, that if we consider the set of all active constraints at  $\mathbf{x}^*$ , then the gradients of those active constraints are linearly independent. So, if  $\mathbf{x}^*$  is a local minimum then there exist  $\lambda_j^*$ , such that  $\nabla f(\mathbf{x}^*) + \sum_j \lambda_j^* \nabla h_j(\mathbf{x}^*) = \mathbf{0}$ .

Now, since we have assumed  $\mathbf{x}^*$  to be a regular point, we have already seen that  $\lambda_0$  is greater than 0. So, ideally there should have been a  $\lambda_0$  here, but since we have a regular point and  $\lambda_0$  is greater than 0 we can divide those conditions by  $\lambda_0$  and by dividing that, the coefficient of this is made one and then we have the corresponding  $\lambda_j^*$ . And then the  $\lambda_j^* h_j(\mathbf{x}^*) = 0$  is as discussed earlier and all the  $\lambda_j^*$  are non-negative.

So, this set of conditions are derived from the conditions that we saw earlier, by ensuring that  $\lambda_0$  is strictly positive and that is ensured by assuming that  $\mathbf{x}^*$  is a regular point.

(Refer Slide Time: 35:37)

**Karush-Kuhn-Tucker (KKT) Conditions**

Consider the problem:

$$\begin{aligned} \min & f(\mathbf{x}) \\ \text{s.t.} & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- $X = \{\mathbf{x} \in \mathbb{R}^n : h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l\}$
- $\mathbf{x}^* \in X, \mathcal{A}(\mathbf{x}^*) = \{j : h_j(\mathbf{x}^*) = 0\}$

**KKT necessary conditions (First Order)**: If  $\mathbf{x}^* \in X$  is a local minimum and a *regular* point, then there exists a unique vector  $\lambda^* = (\lambda_1^*, \dots, \lambda_l^*)^T$  such that

$$\begin{aligned} \nabla f(\mathbf{x}^*) + \sum_{j=1}^l \lambda_j^* \nabla h_j(\mathbf{x}^*) &= \mathbf{0} \\ \lambda_j^* h_j(\mathbf{x}^*) &= 0 \quad \forall j = 1, \dots, l \\ \lambda_j^* &\geq 0 \quad \forall j = 1, \dots, l \end{aligned}$$

Shreshth Sharma - Numerical Optimization

Now, this set of conditions are called Karush-Kuhn-Tucker or in short KKT conditions and, they form a set of conditions which need to be ensured at a local minimum. Now, the conditions were derived, by Karush some time in 1939 and they were independently derive by Kuhn and tucker in 1951. So, the credit goes to, all the three persons who derived those conditions and that is why these conditions are called KKT conditions. So, in this course, whenever I refer to KKT conditions. So, I mean the conditions derived by Karush and Kuhn and Tucker.

So, let us look at this problem and the constraint set  $x$  and let us assume that  $x$  star is a feasible point and let us, collect all the possible set of active constraints at  $x$  star and denote them by script  $A$   $x$  star. So, we have the first order KKT necessary conditions for, the local minimum of this problem. Note that, as I mentioned earlier that this functions and the the function  $f$  as well as the  $h_j x$  are differentiable. In fact I also mention that, they belong to  $c$  two, but for this conditions it is enough that they belong to  $c$  one.

So, if  $x$  star which is the feasible point is a local minimum and it is a regular point, then there exist a unique vector  $\lambda$  star, such that gradient  $f$   $x$  star plus sigma  $j$   $\lambda$   $j$  star gradient  $h_j x$  star is  $0$   $\lambda_j$  star  $h_j x$  star is  $0$  and  $\lambda_j$  is non-negative. So, this conditions are called, first order necessary KKT conditions for the program which is given here. Now, the KKT necessary conditions are more general in the sense that they

all, so use the equality constraints, but. So, for we have not at talked about the equality constraint problem.

So, we will call this conditions as KKT necessary conditions for this program, but later on we will bring in the quality constraints programs also.

(Refer Slide Time: 38:27)

**KKT necessary conditions (First Order)** : If  $\mathbf{x}^* \in X$  is a local minimum and a *regular* point, then there exists a unique vector  $\boldsymbol{\lambda}^* (= (\lambda_1^*, \dots, \lambda_l^*)^T)$  such that

$$\nabla f(\mathbf{x}^*) + \sum_{j=1}^l \lambda_j^* \nabla h_j(\mathbf{x}^*) = \mathbf{0}$$

$$\lambda_j^* h_j(\mathbf{x}^*) = 0 \quad \forall j = 1, \dots, l$$

$$\lambda_j^* \geq 0 \quad \forall j = 1, \dots, l$$

- **KKT point** :  $(\mathbf{x}^*, \boldsymbol{\lambda}^*)$ ,  $\mathbf{x}^* \in X$ ,  $\boldsymbol{\lambda}^* \geq \mathbf{0}$
- **Lagrangian function** :  $\mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}) = f(\mathbf{x}) + \sum_{j=1}^l \lambda_j h_j(\mathbf{x})$
- $\nabla \mathcal{L}_{\mathbf{x}}(\mathbf{x}^*, \boldsymbol{\lambda}^*) = \mathbf{0}$
- $\lambda_j$  : Lagrange multipliers ,  $\lambda_j \geq 0$
- $\lambda_j^* h_j(\mathbf{x}^*) = 0$  : *Complementary Slackness Condition*
- $\lambda_j^* = 0 \quad \forall j \notin \mathcal{A}(\mathbf{x}^*)$

NPTEL Shrihari Shekhar, Numerical Optimization

So, these are the KKT necessary conditions. Now, the point  $\mathbf{x}^*$  and  $\boldsymbol{\lambda}^*$ , is called KKT point and many a times as part of the KKT conditions people also write  $\mathbf{x}^*$  belongs to the feasible set, but here we have mentioned earlier mentioned this. So, it is not part of the KKT conditions, but sometimes there is the practice to you write  $\mathbf{x}^*$  belong to  $f$  part of the KKT condition. So, this  $\mathbf{x}^*$  and  $\boldsymbol{\lambda}^*$  together, is called a KKT point were  $\mathbf{x}^*$  is a feasible point and  $\boldsymbol{\lambda}^*$  is a vector of non-negative numbers.

Now, if we define a function which is called a Lagrangian function, that function is defined as  $f(\mathbf{x}) + \sum \lambda_j h_j(\mathbf{x})$  and remember that, we are assuming that  $f$  and  $h_j$  is are differentiable. So, the first condition of this result, says that the gradient of the Lagrangian function with respect to  $\mathbf{x}$  vanishes. Now, recall that when we discussed about an unconstrained optimization problem, the condition that we got was that if you want to minimize  $f$  of  $\mathbf{x}$ . Then  $\mathbf{x}^*$  is a local minimum of  $f$  implies that, gradient  $f$  at  $\mathbf{x}^*$  is 0 that was for an unconstrained optimization problem.

Now, here we have constraint optimization problem and the condition that now, we get is that  $x^*$  is a local minimum and if it is a regular point, then the gradient of the Lagrangian at  $x^*$  with respect to the variable  $x$  vanishes. So, gradient of the Lagrangian with respect to  $x$  evaluated at  $x^*$  vanishes. Now, these  $\lambda_j$ 's are called Lagrangian multipliers and they have to be non-negative. Also, we have this condition  $\lambda_j h_j(x^*) = 0$  for all  $j$  this condition is called complementary slackness condition.

And note also that  $\lambda_j = 0$  for all  $j$  not in  $A(x^*)$  or in other words for all constraints which are inactive the Lagrangian multipliers at the solution are 0. So, these conditions are called the KKT conditions. So, which say that, the gradient of the Lagrangian at  $x^*$  with respect to  $x$  vanishes, the complementary slackness conditions hold and all the Lagrangian multipliers corresponding to the inequality constraints are non-negative. Remember that, there is a Lagrangian multiplier associated with every constraint.

So, if you have  $l$  constraints, we have  $l$  Lagrangian multipliers and at solution the Lagrangian multipliers corresponding to all the inactive constraints are 0 and since for the active constraints  $h_j(x^*) = 0$ , so  $\lambda_j h_j(x^*) = 0$  note that,  $\lambda_j$  could be 0 for active constraints.

(Refer Slide Time: 42:38)

$$\min f(x)$$

$$\text{s.t. } h_j(x) \leq 0, \quad j = 1, \dots, l$$

$$x \in \mathbb{R}^n$$

- At a local minimum, *active set is unknown*
- Need to investigate all possible active sets for finding KKT points

Shreshth Shrivastava    Numerical Optimization

Now, typically when we want to solve this problem, at a local minimum we do not what are the set of active constraints. So, what we have to do that we have look at all possibilities or all possible sub set of the active sets and see finally, at the solution which set of constraints are active. Suppose, we had known the the active set at the solution earlier, then this problem could have been converted to an equality constraint problem and we would a solved that, but that is typically not the case. So, one needs to investigate, all possible active sets for finding KKT points.

(Refer Slide Time: 48:27)

So, let us take a example suppose, we want to minimize  $x_1$  square plus  $x_2$  square subject to  $x_1$  plus  $x_2$  greater than or equal to 1 and  $x_2$  less than or equal to 1. So, we look at the constraint set. So,  $x_1$  plus  $x_2$  greater than or equal to 1. So, this is  $x_1$  and this is  $x_2$ . So, it is this set  $x_1$  plus  $x_2$  greater than or equal to 1 and  $x_2$  less than or equal to 1 is set and therefore, what we have is the constraint set which is shown it. So, this is going to be the constraint set  $X$  and, we want to minimize this objective function.

Now, at this movement we do not, where does the solution lie. So, so let us assume that this constraint is 1 this constraint is 2 and this point which is. So, we have to consider different possibilities, at the at the solution either this constraints is active or this constraint is active or both the constraints are active and both the constraint are active, at

this point. So, these three possibilities need to be considered. So, let us consider a possibility that.

So, the first case that we want to consider is that,  $x^*$  is equal to  $(0, 1)$ . Now, both the constraints are active. So, we cannot really say about, we cannot say that any of the Lagrangian multipliers corresponding to these constraints are inactive, corresponding to these constraints are 0. So, we can just say  $\lambda_1^*$  is greater than or equal to 0 and  $\lambda_2^*$  is greater than or equal to 0. Now let us write the Lagrangian of this.

So, the Lagrangian will be the objective function  $x_1^2 + x_2^2$  plus  $\lambda_1$  into  $x_2 - 1$ . So, we are calling this constant as 1. So, this constraint is constraint 1 and this constraint is constraint 2; so  $\lambda_1$  into  $x_2 - 1$  plus  $\lambda_2$  into  $1 - x_1 - x_2$ . So, remember that we have converted this 2 to the form  $h_j(x)$  less than or equal to 0. So, it will be  $1 - x_1 - x_2$  less than or equal to 0 and therefore, it is written as  $\lambda_2$  into  $1 - x_1 - x_2$ .

So, now let us look at the gradient of  $f$  at  $x^*$ . So, gradient of  $f$  at  $x^*$  is nothing, but  $2x_1$  and  $2x_2$  evaluated at  $x$  equal to  $x^*$  and  $x^*$  is  $(0, 1)$ . So, this gradient will be  $(0, 2)$ .

(Refer Slide Time: 48:15)

The image shows a whiteboard with handwritten mathematical work. At the top, it states the optimal point  $x^* = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$  and the non-negativity constraints  $\lambda_1^* \geq 0, \lambda_2^* \geq 0$ . Below this, the Lagrangian function is defined as  $\mathcal{L} = x_1^2 + x_2^2 + \lambda_1(x_2 - 1) + \lambda_2(1 - x_1 - x_2)$ . The next line shows the gradient of the objective function at the optimal point:  $\nabla f(x^*) = \begin{pmatrix} 2x_1 \\ 2x_2 \end{pmatrix}_{x=x^*} = \begin{pmatrix} 0 \\ 2 \end{pmatrix}$ . At the bottom, the gradients of the two constraint functions are given:  $\nabla h_1(x^*) = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$  and  $\nabla h_2(x^*) = \begin{pmatrix} -1 \\ -1 \end{pmatrix}$ . The whiteboard also features a toolbar at the top and a logo in the bottom left corner.

Now, let us look at gradient. So, let us take the first constraint, which is  $x_2$  less than or equal to 1. So, gradient  $h_1$   $x^*$  is equal to 0 1 and gradient  $h_2$   $x^*$  is equal to minus 1 minus 1. So, what we are interested in it is.

(Refer Slide Time: 49:02)

$$\nabla f(x^*) = \begin{pmatrix} 2x_1 \\ 2x_2 \end{pmatrix}_{x=x^*} = \begin{pmatrix} 0 \\ 2 \end{pmatrix}$$

$$\nabla h_1(x^*) = \begin{pmatrix} 0 \\ 1 \end{pmatrix}, \quad \nabla h_2(x^*) = \begin{pmatrix} -1 \\ -1 \end{pmatrix}$$

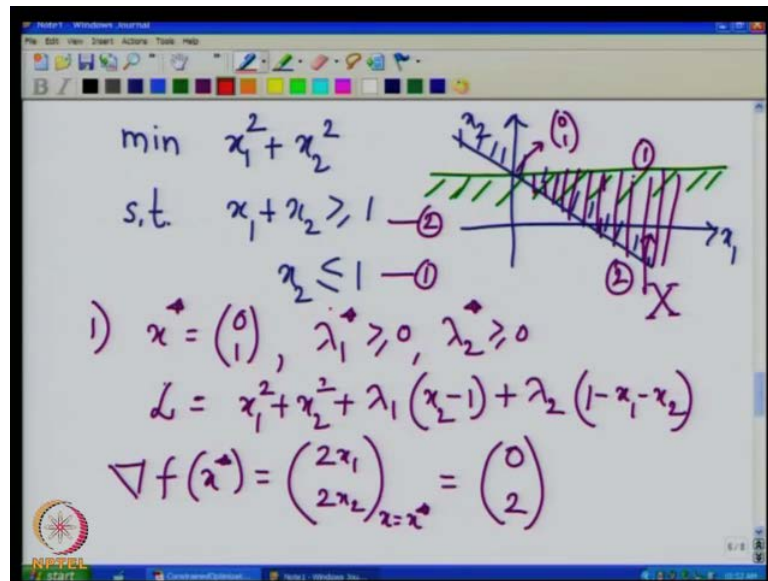

$$\nabla_x L(x^*, \lambda^*) = 0 \Rightarrow \begin{pmatrix} 0 \\ 2 \end{pmatrix} + \lambda_1^* \begin{pmatrix} 0 \\ 1 \end{pmatrix} + \lambda_2^* \begin{pmatrix} -1 \\ -1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

$$\Rightarrow \lambda_2^* = 0, \quad \lambda_1^* = -2 \quad \text{Not feasible}$$

We are interested in finding out remember that, gradient of  $L$  with respect to  $x$  evaluated at  $x^*$   $\lambda^*$  is 0 for KKT point. And, so that implies that  $0 \ 2$  plus  $\lambda_1^*$   $0 \ 1$  plus  $\lambda_2^*$   $-1 \ -1$  is equal to 0 and this implies. So, if you look at this condition. So,  $0$  plus  $\lambda_1^*$   $0$  that is  $0$  plus  $\lambda_2^*$  into  $-1$  is equal to 0. So, which implies that  $\lambda_2^*$  is equal to 0 and  $\lambda_1^*$ . So,  $\lambda_2^*$  is 0. So, which means that  $\lambda_1^*$  is equal to minus 2 for this condition to be satisfied.

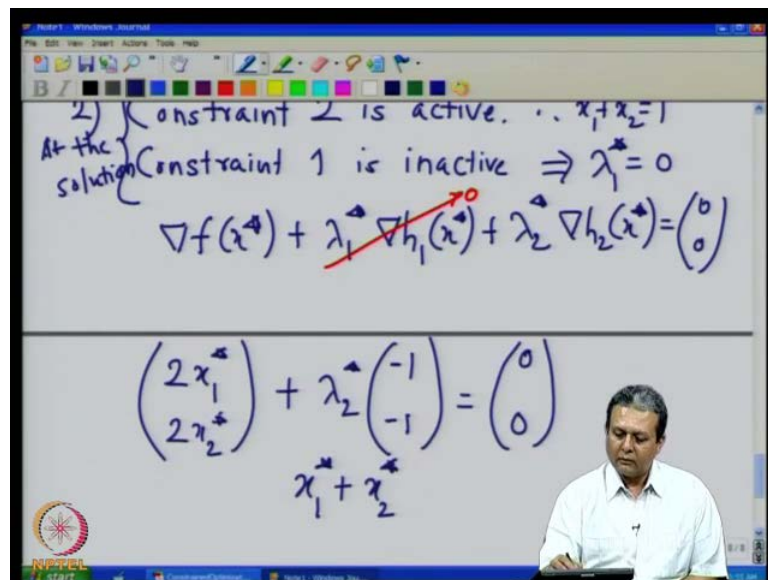

Now, if you look at our result, which is that all is the  $\lambda$  should be non-negative. So, so this is not possible because, all  $\lambda$ s have to be non-negative. So, this is this is not a feasible point, in our case.

(Refer Slide Time: 51:04)

So, the solution of this problem cannot lie at the point 0 1. Now, let us assume that the constraint 2 is active. So, constraint 2 is active means  $x_1 + x_2 = 1$  and  $x_2$  is strictly less than 1, so let us consider that case.

(Refer Slide Time: 51:21)

So, let us consider the case 2 where constraint 2 is active. So, which means that therefore,  $x_1 + x_2 = 1$  because, that is our second constraint and the first constraint is the  $x_2 \leq 1$  and constraint 1 is inactive. So, this 2 are true at the at the solution. So, constraint 1 is inactive, this implies that  $\lambda_1^*$  is equal

to 0 and constraint 2 is active means that at a solution  $x_1^*$  plus  $x_2^*$  is equal to 1. But we do not know what are those  $x_1^*$  and  $x_2^*$  and also we need to find out  $\lambda_2^*$ .

So, so we have  $x_1^*$  plus  $x_2^*$  to be 1 and the other condition is gradient  $f(x^*)$ ,  $f(x^*)$  plus  $\lambda_1^*$  gradient  $h_1(x^*)$  plus  $\lambda_2^*$  gradient  $h_2(x^*)$  is equal to 0 vector; and we are interested in finding  $x_1^*$  and  $x_2^*$  and  $\lambda_2^*$ . So, since  $\lambda_1^*$  is 0 this quantity is 0 and the gradient  $f(x^*)$  is  $2x_1^*$  plus  $2x_2^*$  plus  $\lambda_2^*$  gradient  $h_2(x^*)$ . So, gradient  $h_2(x^*)$  is minus 1 minus 1 is equal to 0. And along with this, we also need to satisfy  $x_1^*$  plus  $x_2^*$  is equal to 1.

(Refer Slide Time: 54:31)

min  $x_1^2 + x_2^2$   
s.t.  $x_1 + x_2 \geq 1$  — (1)  
 $x_2 \leq 1$  — (2)

1)  $x^* = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$ ,  $\lambda_1^* \geq 0$ ,  $\lambda_2^* \geq 0$   
 $\mathcal{L} = x_1^2 + x_2^2 + \lambda_1(x_2 - 1) + \lambda_2(1 - x_2)$   
 $\nabla f(x^*) = \begin{pmatrix} 2x_1 \\ 2x_2 \end{pmatrix}_{x=x^*} = \begin{pmatrix} 0 \\ 2 \end{pmatrix}$

It is this condition that we need to satisfy  $x_1^*$  plus  $x_2^*$  is equal to 1.

(Refer Slide Time: 54:50)

solving

$$\nabla f(x^*) + \lambda_1 \nabla h_1(x^*) + \lambda_2 \nabla h_2(x^*) = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

$$\begin{pmatrix} 2x_1^* \\ 2x_2^* \end{pmatrix} + \lambda_2 \begin{pmatrix} -1 \\ -1 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix} \Rightarrow \begin{cases} \lambda_2 = 2x_1^* \\ \lambda_2 = 2x_2^* \\ x_1^* = x_2^* = \frac{1}{2} \\ \lambda_2 = 1 > 0 \end{cases}$$

$$x_1^* + x_2^* = 1$$

$$\begin{pmatrix} x_1^* \\ x_2^* \end{pmatrix} = \begin{pmatrix} 1/2 \\ 1/2 \end{pmatrix} \quad \& \quad \begin{pmatrix} \lambda_1^* \\ \lambda_2^* \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

Now, from this first condition, what we get this implies that lambda 2 star is equal to 2 x 1 star and that is also equal to 2 x 2 star. So, x 1 star is nothing, but x 2 star and x 1 star equal to x 2 star equal to 1 this implies that x 1 star is equal to x 2 star is equal to half and therefore, lambda 2 star is equal to 1 and this quantity is greater than 0. So, so we have x 1 star x 2 star is equal to half comma half and lambda 1 star lambda 2 star will be 0 and 1. So, all the lambdas are non-negative and x 1 x 1 star x 2 star is a feasible point and satisfies the KKT conditions and therefore.

(Refer Slide Time: 56:24)

min  $x_1^2 + x_2^2$

s.t.  $x_1 + x_2 \geq 1$  — (1)

$x_2 \leq 1$  — (2)

1)  $x^* = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$ ,  $\lambda_1^* \geq 0$ ,  $\lambda_2^* \geq 0$

$L = x_1^2 + x_2^2 + \lambda_1(x_2 - 1) + \lambda_2(1 - x_1 - x_2)$

$\nabla f(x^*) = \begin{pmatrix} 2x_1 \\ 2x_2 \end{pmatrix}_{x=x^*} = \begin{pmatrix} 0 \\ 2 \end{pmatrix}$

So, the the point here, half and half that is going to be our solution. So, this will be  $x_1^*$   $x_2^*$  the actual solution. So, if you recall we started with different possibilities. So, with initially considered this as a solution  $(0, 1)$ , but then we came off with the condition that one of the Lagrangian multiplier become say negative. So, this cannot be a solution and then we decided to consider this, as a active constraint at the solution and we indeed found a point on this set or on this active set such that The Lagrangian multipliers are non-negative and this indeed is a solution of this problem.

So, will see that this is the circle of smallest radius which touches this constraint set  $x$ . So, so this is a circle of radius, which smallest radius because,  $x_1^2 + x_2^2$  is nothing, but radius square of a circle center is that the origin. So, this is the smallest circle which touches this constraint set. So, we will see more about this KKT conditions in the next class.

Thank you.
