Karush-Kuhn-Tucker (KKT) Conditions

Consider the problem:

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- $X = \{\mathbf{x} \in \mathbb{R}^n : h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l\}$
- $\mathbf{x}^* \in X, \mathcal{A}(\mathbf{x}^*) = \{j : h_j(\mathbf{x}^*) = 0\}$

KKT necessary conditions (First Order) : If $\mathbf{x}^* \in X$ is a local minimum and a *regular* point, then there exists a unique vector $\boldsymbol{\lambda}^* (= (\lambda_1^*, \dots, \lambda_l^*)^T)$ such that

$$\begin{aligned} \nabla f(\mathbf{x}^*) + \sum_{j=1}^l \lambda_j^* \nabla h_j(\mathbf{x}^*) &= \mathbf{0} \\ \lambda_j^* h_j(\mathbf{x}^*) &= 0 \quad \forall j = 1, \dots, l \\ \lambda_j^* &\geq 0 \quad \forall j = 1, \dots, l \end{aligned}$$

Shirish Shevade Numerical Optimization

Hello, welcome back. So, in the last class, we started looking at KKT conditions for a constrained optimization problem. In particular, we considered this problem where we want to minimize f of x subject to the inequality constraints of the type $h_j(x)$ less than or equal to 0. There are one such inequality constraints. So, we define the constraints said to be capital X like this and for a given feasible point x^* , we defined in active set $\mathcal{A}(x^*)$ to be a set of all constraints which are satisfied with equality. So, set of all j 's such that $h_j(x^*)$ is equal to 0 and then, we have the necessary conditions for a local minimum. These are the first order condition because they use the first order derivative information.

So, if we take a feasible x^* , then that feasible x^* is a regular point and is also a local minimum. Then, there exists a unique vector λ^* , such that these conditions hold. So, gradient effect star is written as a non-negative linear combinations of the gradients of the active in equality constraints and for the inactive inequality constraints,

we can say lambda j star to be 0. So, in all we have all lambda j star non negative and on this condition holds.

(Refer Slide Time: 02:12)

KKT necessary conditions (First Order) : If $\mathbf{x}^* \in X$ is a local minimum and a *regular* point, then there exists a unique vector $\boldsymbol{\lambda}^* (= (\lambda_1^*, \dots, \lambda_l^*)^T)$ such that

$$\nabla f(\mathbf{x}^*) + \sum_{j=1}^l \lambda_j^* \nabla h_j(\mathbf{x}^*) = \mathbf{0}$$

$$\lambda_j^* h_j(\mathbf{x}^*) = 0 \quad \forall j = 1, \dots, l$$

$$\lambda_j^* \geq 0 \quad \forall j = 1, \dots, l$$

- **KKT point** : $(\mathbf{x}^*, \boldsymbol{\lambda}^*)$, $\mathbf{x}^* \in X$, $\boldsymbol{\lambda}^* \geq \mathbf{0}$
- **Lagrangian function** : $\mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}) = f(\mathbf{x}) + \sum_{j=1}^l \lambda_j h_j(\mathbf{x})$
- $\nabla \mathcal{L}_{\mathbf{x}}(\mathbf{x}^*, \boldsymbol{\lambda}^*) = \mathbf{0}$
- λ_j : Lagrange multipliers, $\lambda_j \geq 0$
- $\lambda_j^* h_j(\mathbf{x}^*) = 0$: *Complementary Slackness Condition*
- $\lambda_j^* = 0 \quad \forall j \notin \mathcal{A}(\mathbf{x}^*)$

 Shrish Shekhar Numerical Optimization

So, for the inactive inequality constraints, λ_j is less than 0. So, for those constraints λ_j will be 0 and for the active inequality constraints, λ_j will be non-negative. So, we saw that $(\mathbf{x}^*, \boldsymbol{\lambda}^*)$ is KKT point, where \mathbf{x}^* is feasible point and $\boldsymbol{\lambda}^*$ is non-negative. So, such point we are going to call them as KKT points and if you define the lagrangian function to be $f(\mathbf{x}) + \sum_{j=1}^l \lambda_j h_j(\mathbf{x})$, where j is from 1 to l , then this condition can be written as the gradient of the lagrangian with respect to \mathbf{x} evaluated at \mathbf{x}^* and $\boldsymbol{\lambda}^*$ is 0 or evaluated at a KKT point is 0 and multiplies λ_j is or call the Lagrange multipliers and they are non-negative.

(Refer Slide Time: 03:16)

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- At a local minimum, *active set is unknown*
- Need to investigate all possible active sets for finding KKT points

Example:

$$\begin{aligned} \min \quad & x_1^2 + x_2^2 \\ \text{s.t.} \quad & x_2 \leq 1 \\ & x_1 + x_2 \geq 1 \end{aligned}$$

The slide also features the NPTEL logo and the name 'Shrish Shrivastava' at the bottom.

Moreover, we have this complimentary slackness condition which is mentioned here that $\lambda_j^* h_j(\mathbf{x}^*) = 0$ and $\lambda_j^* = 0$ for all constraints which are inactive at \mathbf{x}^* . So, all this analysis holds, provided the active set is known and typically in practice, the active set is not known.

(Refer Slide Time: 03:56)

A hand-drawn graph on a coordinate system with axes x_1 and x_2 . The origin is marked with a blue circle. A horizontal line is drawn at $x_2 = 1$, labeled with a red arrow and $x_2 = 1$. A diagonal line is drawn from the bottom-left to the top-right, labeled with a red arrow and $x_1 + x_2 = 1$. The region between these two lines is shaded with diagonal lines. A red 'X' marks a point in the shaded region. A red arrow points to the origin with the label $\mathbf{x}^* = \begin{pmatrix} 1/\sqrt{2} \\ 1/\sqrt{2} \end{pmatrix}$. The NPTEL logo and the name 'Shrish Shrivastava' are visible at the bottom.

So, one has to investigate all possible active sets for finding KKT points and we saw one example in the last class that if you want to solve this problem, minimize $x_1^2 + x_2^2$ subject to the $x_2 \leq 1$ and $x_1 + x_2 \geq 1$

to 1. So, we have $x_1 \leq x_2$ and here, we have one constraint which is $x_1 + x_2 \geq 1$ and other constraints which is $x_2 \leq 1$. So, if you look at the feasible region, so this is the constraints which satisfied $x_2 = 1$ and this is the constraint which satisfies $x_1 + x_2 = 1$ and our set x . If there were a feasible region where $x_2 \leq 1$ and $x_1 + x_2 \geq 1$ and our aim is to minimize the objective functions which contours are like this.

So, you will see that at this point, the minimum occurs and that point is, but then we do not know the active constraints beforehand. So, we have to check all possibilities. So, if we assume that at this point the minimum occurs, then we satisfy the KKT condition or only this constraint $x_2 = 1$ is active and this constraint is inactive. That means a solution lies somewhere on this line. Then, what happens is we saw that the solution cannot lie here and we saw in the last class that the solution indeed lies here, we were able to take a x^* to be half-half and the corresponding λ which is positive, such that this condition, the KKT conditions are satisfied. Now, I will leave it is an exercise to check whether the solution does lie on this line. So, in other words, we have to check all possible combinations of constraints and treat them as active sets and see, which are the possible KKT points.

(Refer Slide Time: 06:53)

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- At a local minimum, *active set is unknown*
- Need to investigate all possible active sets for finding KKT points

Example:

$$\begin{aligned} \min \quad & x_1^2 + x_2^2 \\ \text{s.t.} \quad & x_2 \leq 1 \\ & x_1 + x_2 \geq 1 \end{aligned}$$

- A KKT point can be a local maximum

Example:

$$\begin{aligned} \min \quad & -x^2 \\ \text{s.t.} \quad & x \leq 0 \end{aligned}$$

NIPTEL Shriniv Srinivasa Numerical Optimization

So, we saw this example in the last class. Now, another important point that needs to be noted is that KKT point; it can also be a local maximum. So, satisfying KKT conditions does not mean that we will always get a local minimum. So, let us consider one example where we want to minimize minus x 1 minus x square subject to the constraints x less than or equal to 0. So, this is just a one-dimensional optimization problem.

(Refer Slide Time: 07:32)

$$\begin{aligned} \min \quad & -x \\ \text{s.t.} \quad & x \leq 0 \end{aligned}$$

$$\mathcal{L}(x, \lambda) = -x^2 + \lambda x$$
$$\frac{\partial \mathcal{L}}{\partial x} = 0 \Rightarrow -2x + \lambda = 0$$

1) At x^* , the constraint is active

$$\therefore x^* = 0$$
$$\therefore \frac{\partial \mathcal{L}}{\partial x} \Big|_{(x^*, \lambda^*)} = 0 \Rightarrow \lambda^* = 0$$

$\therefore (0, 0)$ is a KKT point

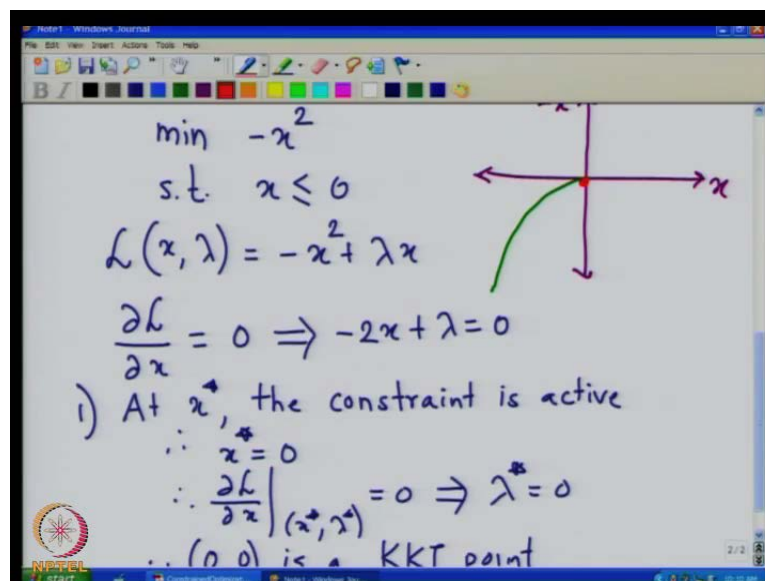

NIPTEL

So, we want to minimize minus x square subject to the constraints x less than or equal to 0. Now, if you write the lagrangian, so lagrangian of x lambda will be minus x square

plus lambda x. So, partial derivative of l with respect to s and that is 0 at the first order KKT condition. So, we will equate that to 0 to get a KKT point and this implies that minus 2 x plus lambda is equal to 0. Now, if you consider the case one, where we divide the constraints into two parts, so at the solution suppose this is active constraints. So, in other words, at x star, the constraints is there, only one constraints is there. So, suppose that that constraint is active.

So, therefore, x star is equal to 0 because at x star h j x star equal to is an active constraint. So, if we put x star equal to 0, what do we get? Therefore, gradient of l with respect to x evaluated at x star lambda star equal to 0 implies lambda star equal to 0 because x star is 0. Therefore, 0, of 0 is a KKT point because our KKT necessary condition just say that lambda star has to be non-negative and so in this case, it is 0 and a corresponding point x star is 0.

(Refer Slide Time: 10:15)

Now, let us see if we look at this function, so if you take the function minus x square and the constraints x less than or equal to 0. So, x that is less than or equal to 0 means we are interested in non-positive values of x and the function would be like this. So, you will see that the function is unbounded. So, the minimum of minus x square will not be active because the function is unbounded.

Now, let us look at the point. So, let us look at the point x star is equal to 0 which is this point which we were considering and we were able to get a non-negative lagrangian

multiplier corresponding to x^* and we got 0 as KKT point and we will see from this figure that in fact, this point is a local maximum. So, although this point satisfies the KKT conditions, it is the local maximum. Now, therefore, satisfying KKT conditions does not guarantee local minimum. Now similarly, one can work out the other condition that at x^* , the constraints is inactive. That means, at x^* λ is less than 0 and then, one can find out what happens to this condition as well as the condition that λ^* has to be non-negative. So, I leave it as an exercise, ok.

(Refer Slide Time: 12:27)

Constraint Qualification

- Every local minimum need not be a KKT point
- Example [Kuhn and Tucker, 1951]¹

$$\begin{array}{ll} \min & -x_1 \\ \text{s.t.} & x_2 - (1 - x_1)^3 \leq 0 \\ & x_2 \geq 0 \end{array}$$

¹H.W. Kuhn and A.W. Tucker, *Nonlinear Programming*, in Proceedings of the Second Berkeley Symposium on Mathematical Statistics and Probability, J. Neyman, ed., Berkeley, CA, 1951, University of California Press, pp. 481–492.

Shirish Shekale Numerical Optimization

(Refer Slide Time: 13:15)

Now, let us look at another important point that needs to be understood that is called a constraint qualification. Now, every local minimum that we get need not be your KKT point and one example which was given by Kuhn and Tucker sometime back in 1951 was problem where we want to minimize minus x_1 subject to re-constraint at x_2 minus 1 minus x_1 cube less than or equal to 0 and x_2 greater than or equal to 0 .

So, let us look at this example. So, suppose this point is $1, 0$ and so this is one constraint and the other constraint is x_2 greater than or equal to 0 and we want to minimize minus x_1 subject to the constraint x_2 minus 1 minus x_1 cube less than or equal to 0 and x_2 greater than or equal to 0 . So, we will write it as minus x_2 less than or equal to 0 . So, this is our constraint set and we want to minimize minus x_1 .

Now, let us look at this point. Now, at this point, we will see that this is point and this is the solution to this problem because we want to find out the maximum value of x_1 , where these constraints are satisfied and that turns out to be this value, but let us look at the gradients of the objective functions and the constraints. So, this is x^* . So, x^* is given here. Now, at x^* which is equal to this point, what is the gradient of f of x^* ? So, gradient of f of x^* will be minus $1, 0$.

Let us take the first constraints. So, gradient h_1 x^* will be $0, 1$ and where evaluating it at $x_1, 0$. So, the x_1 component of this first gradient will be 0 and the gradient of the second component, the gradient of the inequality constraints will be $0, \text{minus } 1$. Now, let

us plot these constraints on this figure. So, gradient $f x^*$ is pointing in this direction. So, this is gradient $f x^*$ and gradient $h_1 x^*$ is pointing in this direction. So, gradient $h_1 x^*$ and gradient $h_2 x^*$ is pointing in this direction.

Now, the first order KKT condition says that gradient $f x^*$ is written as a non-negative linear combinations of the gradients of the active inequality constraints. Now, at this point x^* , both the constraints are active. So, both the inequality constraints are active at this point x^* and you will see that gradient $h_1 x^*$ and gradient $h_2 x^*$, all are not linearly independent in this two-dimensional space. Therefore, since they are not truly linearly independent vector seen two-dimensional space, therefore, they cannot form basis for a two-dimensional space. Therefore, gradient $f x^*$ cannot be written as a non-negative linear combinations of gradient $h_1 x^*$ or gradient $h_2 x^*$.

In fact, you will see that now gradient $f x^*$ is an orthogonal 2 gradient $h_1 x^*$ as well as gradient $h_2 x^*$. So, even though x^* is an optimal point of this problem. It is not a KKT point and that is because x^* is not a regular point. The gradients of the active inequality constraints are not linearly independent in this case and therefore, KKT conditions are not satisfied at this point.

(Refer Slide Time: 18:40)

Constraint Qualification

- Every local minimum need not be a KKT point
- Example [Kuhn and Tucker, 1951]¹

$$\begin{aligned} \min \quad & -x_1 \\ \text{s.t.} \quad & x_2 - (1 - x_1)^3 \leq 0 \\ & x_2 \geq 0 \end{aligned}$$

- **Linear Independence Constraint Qualification (LICQ)** :
 $\nabla h_j(x^*), j \in \mathcal{A}(x^*)$ are linearly independent
- **Mangasarian-Fromovitz Constraint Qualification (MFCQ)**
 $\{d : \nabla h_j(x^*)^T d < 0, j \in \mathcal{A}(x^*)\} \neq \emptyset$

¹H.W. Kuhn and A.W. Tucker, *Nonlinear Programming*, in Proceedings of the Second Berkeley Symposium on Mathematical Statistics and Probability, J. Neyman, ed., Berkeley, CA, 1951, University of California Press, pp. 481–492.

Shriroh Shewale - Numerical Optimization

So, it is very important to have the regularity assumption for getting the KKT points and therefore, this linear independence constraint qualification is very important constraint qualification condition and that says that the gradients of the active constraints active at x

star how to be linearly independent. So, that implies that x^* becomes a regular point and once it is a regular point, once we have this linearly independent vector, we can write the gradient of f of x^* as non-negative linear combinations of the variance of these points. If they are not linearly independent, we can write gradient f of x^* as the non-negative linear combinations of x .

So, this is the very important condition that needs to be satisfied. Then, we can say that under the linear independence constraint qualification if x^* is the local minimum, then first order KKT conditions are satisfied or they are necessary. Now, Mangasarian and Fromovitz also gave another constraints qualification condition and that says that if we consider the problem of minimizing $f(x)$ subject to $h_j(x) \leq 0$, then there exists at least one direction which makes an off choose angle with all the gradients of the active inequality constraints. So, gradient $h_j(x^*)^T d$ is less than 0 for all j belonging to the set of active constraints at x^* .

(Refer Slide Time: 20:37)

Consider the problem (CP):

$$\begin{aligned} \min \quad & f(x) \\ \text{s.t.} \quad & h_j(x) \leq 0, \quad j = 1, \dots, l \\ & x \in \mathbb{R}^n \end{aligned}$$

- Assumption: $f, h_j, j = 1, \dots, l$ are differentiable convex functions
- CP is a *convex program*
- $X = \{x \in \mathbb{R}^n : h_j(x) \leq 0, j = 1, \dots, l\}$
- Every local minimum of a convex program is a global minimum
- The set of all optimal solutions to a convex program is convex

If $x^* \in X$ is a *regular point*, then for x^* to be a global minimum of CP, first order KKT conditions are necessary and sufficient.

MPTEL Shrish Shevade Numerical Optimization

So, there exists at least one direction which satisfies this. So, this is another constraint qualification condition that was proposed by Mangasarian and Fromovitz. Now, let us consider a problem to minimize $f(x)$ subject to the constraint $h_j(x) \leq 0$, but this time we make an assumption that f and $h_j(x)$ are differentiable convex functions. So, the important point here is that both f as well as $h_j(x)$ are convex functions and also they are differentiable.

Now, under this situation turns out that the first order KKT conditions are sufficient if x^* is the regular point. Now, we are optimizing or minimizing a convex function subject to the constraint that $h_j(x)$ is less than or equal to 0. Now, as we have seen earlier that if $h_j(x)$ is less than or equal to 0, where h_j is a convex function and then, a set x such that $h_j(x)$ less than or equal to 0 is a convex set. Now, if you combine different convex sets or intersect different convex set, then we know that the intersection of convex set is also the convex set.

So, the constraint here is the convex set. The objective function to minimize is the convex function. So, such a program is called a convex program and clearly the set x is a convex set. Now, there are two important results that I would like to mention here to a convex program and the first result is that every local minimum of a convex program is a global minimum. We saw a variant of this result when we studied convex functions that under the constraint case, we saw this result and those ideas can be extended to a constraint problem like this which is in this case is a convex program.

So, every local minimum of a convex program is a global minimum. So, there is no question of local minima as far as convex programs are concerned. Every local minimum is a global minimum and not only that, all these global minima when they are found, they form a convex set. So, the set of all optimal solutions to a convex program is convex. So, this is a very important result again that not only do we have the problem of local minima for convex programs, but the set of all solutions to a convex program is a convex set.

So, this result again we have seen earlier that even if you take an unconstrained optimization problem where we want to minimize a convex function, then the set of all optimal solutions is a convex set and that result can easily be extended to a constraint problem constraint convex program which is given here that a set of all optimal solutions form a convex set. So, here we have an important result that says that x^* is a regular point and then, for x^* to be a global minimum of a convex program c^* , the first order condition KKT conditions are necessary and sufficient.

(Refer Slide Time: 24:56)

Proof.

Let $(\mathbf{x}^*, \boldsymbol{\lambda}^*)$ be a KKT point. We need to show that \mathbf{x}^* is a global minimum of CP. We use the convexity of f and h_j to prove this. Consider any $\mathbf{x} \in X$. For a convex function f ,

$$f(\mathbf{x}) \geq f(\mathbf{x}^*) + \nabla f(\mathbf{x}^*)^T (\mathbf{x} - \mathbf{x}^*).$$

$$f(\mathbf{x}) \geq f(\mathbf{x}^*) + \sum_j \lambda_j^* h_j(\mathbf{x})$$

$$\geq f(\mathbf{x}^*) + \nabla f(\mathbf{x}^*)^T (\mathbf{x} - \mathbf{x}^*)$$

$$+ \sum_j \lambda_j^* (h_j(\mathbf{x}^*) + \nabla h_j(\mathbf{x}^*)^T (\mathbf{x} - \mathbf{x}^*))$$

$$= (f(\mathbf{x}^*) + \sum_j \lambda_j^* h_j(\mathbf{x}^*))$$

$$+ (\nabla f(\mathbf{x}^*) + \sum_j \lambda_j^* \nabla h_j(\mathbf{x}^*))^T (\mathbf{x} - \mathbf{x}^*)$$

$$= f(\mathbf{x}^*) \quad \forall \mathbf{x} \in X \Rightarrow \mathbf{x}^* \text{ is a global}$$

So, we have already seen that if \mathbf{x}^* is local minimum, then first order conditions are necessary. Now, we will show that for convex program, these conditions are sufficient and to show that we will need the convexity of f and the function h_j . So, let us see how to prove that. So, let us take a KKT point \mathbf{x}^* and $\boldsymbol{\lambda}^*$ and since, it is a KKT point \mathbf{x}^* belongs to the feasible region and $\boldsymbol{\lambda}^*$ is a non-negative vector. Now, what we want to show is that \mathbf{x}^* is a global minimum of a convex program, where f is a convex function and h_j are convex functions and we also assume that they are sufficiently smooth. Now, in this case, we just need a first order derivative. So, it is enough to assume that they belong to class C^1 of function. Now, to prove that the KKT, first order KKT conditions are sufficient, we will use the convexity of the functions f and h_j and for that purpose, let us consider any point \mathbf{x} in the feasible region.

Now, we have seen this result earlier when we studied convex functions that the (()) approximation of a convex function at \mathbf{x}^* does not over estimate the function. So, $f(\mathbf{x})$ is always greater than or equal to $f(\mathbf{x}^*) + \nabla f(\mathbf{x}^*)^T (\mathbf{x} - \mathbf{x}^*)$. So, these results we have seen earlier. So, let us make use of these results to prove that a KKT point under the regularity assumption is a local minimum is a sufficient condition for a local minimum of a convex programming problem. Now, since \mathbf{x}^* is a feasible point, $h_j(\mathbf{x}^*) \leq 0$ and $\boldsymbol{\lambda}^*$ is a KKT point. So, $\boldsymbol{\lambda}^*$ has to be non-negative. So, this quantity here is a non-positive quantity and therefore, we can write $f(\mathbf{x})$ to be greater than or equal to $f(\mathbf{x}^*) + \sum_j \lambda_j^* h_j(\mathbf{x})$ because $f(\mathbf{x})$ is less than or equal to $f(\mathbf{x}^*) + \nabla f(\mathbf{x}^*)^T (\mathbf{x} - \mathbf{x}^*)$ and $\lambda_j^* h_j(\mathbf{x})$ is less than or equal to $\lambda_j^* (h_j(\mathbf{x}^*) + \nabla h_j(\mathbf{x}^*)^T (\mathbf{x} - \mathbf{x}^*))$.

Now, let us make use of these results. So, expand $f(x)$ around x^* and use this inequality. So, $f(x)$ is greater than or equal to $f(x^*) + \text{gradient } f(x^*)^T (x - x^*)$ and since, each $h_j(x)$ is also a convex function, $h_j(x)$ is greater than or equal to $h_j(x^*) + \text{gradient } h_j(x^*)^T (x - x^*)$. So, in this we have used the convexity of both f and $h_j(x)$. Now, let us rearrange these terms together. So, let us combine this term with this term and then, all the terms in all the gradients of f and gradient of $h_j(x)$ will combine them together. So, this gives us, so this quantity is nothing, but $f(x^*) + h_j(x^*) \sum \lambda_j^* h_j(x^*) +$. Let us combine terms in one gradients, so $\text{gradient } f(x^*) + \sum \lambda_j^* \text{gradient } h_j(x^*)^T (x - x^*)$.

Now, we have seen that x^* λ^* is a, we have assumed that x^* λ^* is a KKT point and satisfies necessary KKT conditions. So, since the complimentary slackness condition is satisfied, we have $\lambda_j^* h_j(x^*) = 0$. So, every term in this summation is 0.

Now, let us look at this point. Since, the first order KKT conditions are satisfied $\text{gradient } f(x^*) + \sum \lambda_j^* \text{gradient } h_j(x^*)^T = 0$. So, this is 0, this is 0 and what we are left with? It is left with $f(x^*)$ and therefore, $f(x)$ is greater than or equal to $f(x^*)$ for all feasible x and that means that x^* is a global minimum of the convex program. So, x^* is a global minimum of the convex program that we have considered.

(Refer Slide Time: 20:37)

Consider the problem (CP):

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- Assumption: $f, h_j, j = 1, \dots, l$ are differentiable convex functions
- CP is a *convex program*
- $X = \{\mathbf{x} \in \mathbb{R}^n : h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l\}$
- Every local minimum of a convex program is a global minimum
- The set of all optimal solutions to a convex program is convex

If $\mathbf{x}^* \in X$ is a *regular point*, then for \mathbf{x}^* to be a global minimum of CP, first order KKT conditions are necessary and sufficient.

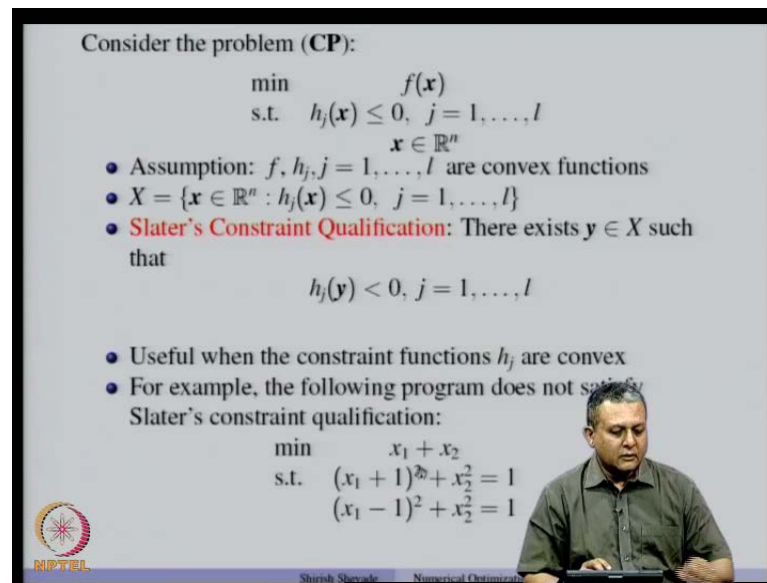

NIPTEL

Shrish Shewale Numerical Optimization

So, if we find the KKT points of a convex programming problem, then under the regularity assumptions, those KKT points are indeed or those KKT points give us the optimal solution \mathbf{x}^* to a given convex program. So, this is a very important result as far as convex programming problems are concerned. Now, interestingly this result can be extended when we add the equality constraints to this program. The only thing that one has to keep in mind is that when we add the equality constraints, those equality constraints have to be of the type $\mathbf{a}_i^T \mathbf{x} - b_i$ because only then on the constraint set will remain a convex set. So, we will see those results when we introduce the equality constraints to our optimization problem. So far, we have been dealing only with the problems of this type where we want to minimize $f(\mathbf{x})$ subject to any equality constraint, but those results can easily be extended to general convex programming problem. We will see those things sometime later.

(Refer Slide Time: 30:57)

Consider the problem (CP):

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- Assumption: $f, h_j, j = 1, \dots, l$ are convex functions
- $X = \{\mathbf{x} \in \mathbb{R}^n : h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l\}$
- **Slater's Constraint Qualification:** There exists $\mathbf{y} \in X$ such that

$$h_j(\mathbf{y}) < 0, \quad j = 1, \dots, l$$

- Useful when the constraint functions h_j are convex
- For example, the following program does not satisfy Slater's constraint qualification:

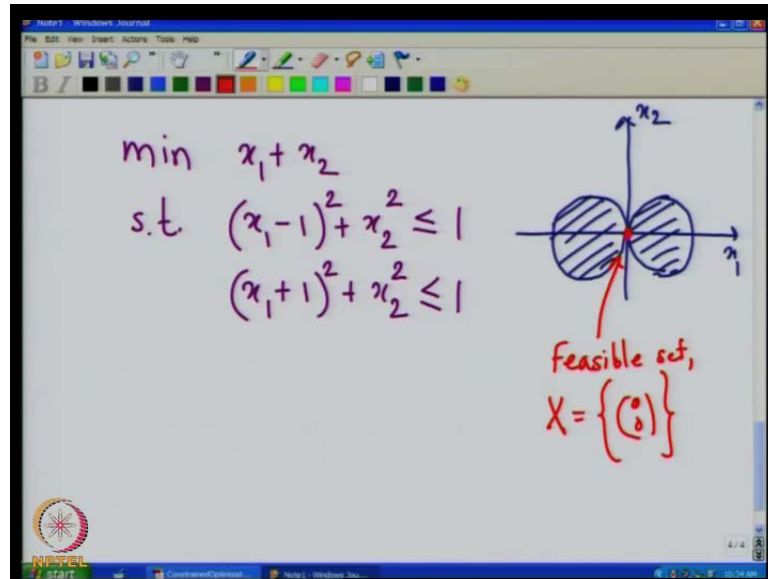

$$\begin{aligned} \min \quad & x_1 + x_2 \\ \text{s.t.} \quad & (x_1 + 1)^2 + x_2^2 = 1 \\ & (x_1 - 1)^2 + x_2^2 = 1 \end{aligned}$$

 Shrish Shrivastava Numerical Optimization

Now, let us again go back to our convex program where the function f is convex function and $h_j(\mathbf{x})$ are again convex function and the constraint set is a convex set. So, the feasible set X becomes a convex set because it is an intersection of all convex sets. Now, for convex programs, there is a constraint qualification condition proposed by Slater and that condition says that there exists a feasible point \mathbf{y} , such that $h_j(\mathbf{y}) < 0$ for all for all the inequality constraints.

So, what does this mean? This means that there exists some feasible point which lies in the interior of the feasible set X . So, that means that the interior of the feasible set is not empty. So, this Slater's constraint qualification is useful especially for convex program problems and it is easy to check that this condition to check whether this condition is satisfied or not.

(Refer Slide Time: 32:57)

So, typically for convex programs, we will use Slater's constraints qualification and to show the importance of this Slater's constraints qualification, let us consider an example where we want to minimize this problem. So, suppose if we consider this problem minimize $x_1 + x_2$ subject to the constraints that $x_1 - 1$ square plus x_2 square less than or equal to 1 and $x_1 + 1$ square plus x_2 square is less than or equal to 1.

So, the first constraint is a circle of radius one centered around 1, 0 in the second constraint is again, so this is the point inside the second circle and these are the points inside the first. So, the feasible region will be only this point feasible set x is nothing, but the origin, the dashed portion here shows the points inside the circle. So, from one set, so this is the feasible region corresponding to the second constraint. This is the feasible region corresponding to a first constraint and when we intersect, we get only one point which is a single term point.

(Refer Slide Time: 36:00)

Consider the problem (CP):

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- Assumption: $f, h_j, j = 1, \dots, l$ are convex functions
- $X = \{\mathbf{x} \in \mathbb{R}^n : h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l\}$
- **Slater's Constraint Qualification:** There exists $\mathbf{y} \in X$ such that

$$h_j(\mathbf{y}) < 0, \quad j = 1, \dots, l$$

- Useful when the constraint functions h_j are convex
- For example, the following program does not satisfy Slater's constraint qualification:

$$\begin{aligned} \min \quad & x_1 + x_2 \\ \text{s.t.} \quad & (x_1 + 1)^2 + x_2^2 = 1 \\ & (x_1 - 1)^2 + x_2^2 = 1 \end{aligned}$$

$(0, 0)^T$ is the global minimum; but it is *not a KKT point*.

Shrish Shrivastava Numerical Optimization

Now, this point, this feasible set being a single term set has no interior. So, one can check that this point is a local minimum, but it does not satisfy the Slater's constraints qualification condition. So, this point which we have got which is the origin, which is the feasible set, is the global minimum, but it is not a KKT point. So, one can check that this point is not a KKT point, although it is a global minimum and that to happen because we had a constraint set which is also single term set in this case and that did not satisfies Slater's constraints qualification.

So, many times for convex programs which is possible to have a minimum, but that minimum may not satisfy KKT conditions and that is mainly because the Slater's constraint qualification is not satisfied, that is that did not exist a point which slice in the interior of the feasible set or in other words, the feasible set does not have interior or has empty interior, ok.

(Refer Slide Time: 37:22)

Consider the problem:

$$\begin{aligned} \min & \quad f(\mathbf{x}) \\ \text{s.t.} & \quad e_i(\mathbf{x}) = 0, \quad i = 1, \dots, m \\ & \quad \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- Assumption: $f, e_i, i = 1, \dots, m$ are smooth functions
- $X = \{\mathbf{x} \in \mathbb{R}^n : e_i(\mathbf{x}) \leq 0, i = 1, \dots, m\}$
- Let $\mathbf{x} \in X$, $\mathcal{A}(\mathbf{x}) = \{i : e_i(\mathbf{x}) = 0\} = \{1, \dots, m\}$

Definition

A vector $\mathbf{d} \in \mathbb{R}^n$ is said to be a tangent of X at \mathbf{x} if either $\mathbf{d} = \mathbf{0}$ or there exists a sequence $\{\mathbf{x}^k\} \subset X$, $\mathbf{x}^k \neq \mathbf{x} \forall k$ such that

$$\mathbf{x}^k \rightarrow \mathbf{x}, \quad \frac{\mathbf{x}^k - \mathbf{x}}{\|\mathbf{x}^k - \mathbf{x}\|} \rightarrow \frac{\mathbf{d}}{\|\mathbf{d}\|}.$$

NIPTELL Shrishank Shrivastava Numerical Optimization

So far, we have studied problems of type where belongs to minimize effects subject to the constraints $h_j(x)$ is less than or equal to 0. Now, the idea that we have studied so far cannot be directly used for equality constraint problem. Now, let us start looking at the equality constraint problems. Now, you will see that the constraints are of the type $e_i(x)$ equal to 0. I am going from 1 to m. Now, there could be $e_i(x)$ could be as simple as a i transpose x minus b_i equal to 0 as it could be different function non-linear function of x .

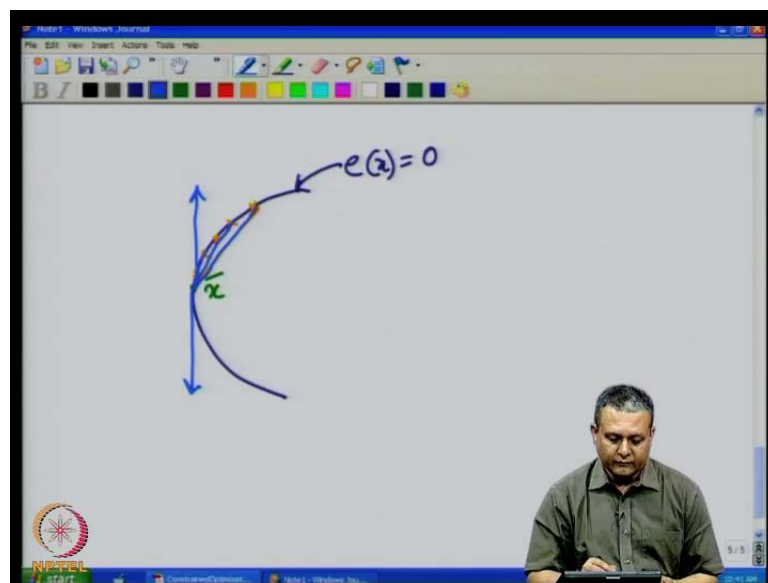

Now, we can arrive at some algebraic condition for the local minima of this problem. So, that is what we are going to study now. So, let us again assume that the objective function f and e_i 's are smooth functions and for the first order conditions will require them to continuously differentiable, and for the second order condition will require them to be quite continuously differentiable. So, here I just mention them as smooth functions. So, let us collect all possible x . We satisfy $e_i(x)$ equals to 0, it should be $e_i(x)$ equals to 0.

Now, let us consider a feasible point and then, see what constraints are active at the feasible points. So, as per our definition, the set of constraints which are satisfied with equality, so a set of all i 's such that e_i is equal to 0 and since, x is a feasible point. So, that means that $e_i(x)$ equal to 0 for all i which means that all the equality constraints are active at any given feasible x . So, this set is nothing, but all m equality constraints. Now, we look at the definition of a tangent of the feasible set at a given point x . That definition helps us to characterize the feasible directions using algebraic conditions. So, a d

dimensional vector d is said to be a tangent of x at x tangent of the feasible set at a given point x .

Remember that x also is part of the feasible set here. So, if either d is equal to 0 or if we consider a sequence x_k in the feasible set, where x none of the x_k is equal to x for all k , such that the sequence converges to x and if we take the quad joining the x and x_k and then, like though vector in the normalize vector x_k minus x by norm of x_k minus x that converges to d by norm d .

(Refer Slide Time: 40:59)

So, such a vector d is called a tangent vector. So, suppose we have n constraints. So, this is the constraints $e(x) = 0$. Now, if we take a point \bar{x} . Now, we take a sequence x_k which is part of this feasible set. So, let us take the sequence, point which converges to this point. Now, if we take a quad joining each of this, so in the limit this quad will have this direction and this is the tangent to this surface at \bar{x} can also have a tangent which is in this other direction by considering another sequence. So, this becomes a tangent set to this feasible region at \bar{x} . Now, in two-dimensional space, this tangent, this one line, now three-dimensional space, it will be a tangent length and so on and so forth.

(Refer Slide Time: 43:26)

Consider the problem:

$$\begin{aligned} \min & \quad f(\mathbf{x}) \\ \text{s.t.} & \quad e_i(\mathbf{x}) = 0, \quad i = 1, \dots, m \\ & \quad \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- Assumption: $f, e_i, i = 1, \dots, m$ are smooth functions
- $X = \{\mathbf{x} \in \mathbb{R}^n : e_i(\mathbf{x}) \leq 0, \quad i = 1, \dots, m\}$
- Let $\mathbf{x} \in X$, $\mathcal{A}(\mathbf{x}) = \{i : e_i(\mathbf{x}) = 0\} = \{1, \dots, m\}$

Definition

A vector $\mathbf{d} \in \mathbb{R}^n$ is said to be a tangent of X at \mathbf{x} if either $\mathbf{d} = \mathbf{0}$ or there exists a sequence $\{\mathbf{x}^k\} \subset X$, $\mathbf{x}^k \neq \mathbf{x} \forall k$ such that

$$\mathbf{x}^k \rightarrow \mathbf{x}, \quad \frac{\mathbf{x}^k - \mathbf{x}}{\|\mathbf{x}^k - \mathbf{x}\|} \rightarrow \frac{\mathbf{d}}{\|\mathbf{d}\|}.$$

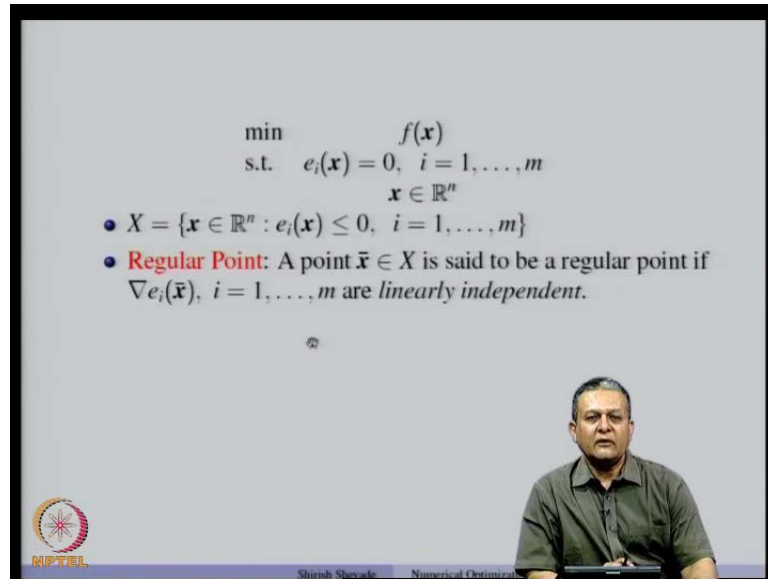

The collection of all tangents of X at \mathbf{x} is called the *tangent set* at \mathbf{x} and is denoted by $T(\mathbf{x})$.

Shrinath Shrivastava Numerical Optimization

So, we collect all feasible sequences in the region which converge to $\bar{\mathbf{x}}$ and then, if we take a quad joining those \mathbf{x}^k and $\bar{\mathbf{x}}$ and normalize them to a unit vector, then we get \mathbf{d} and then, find limiting direction of those quads that will give us the tangent to the feasible set at $\bar{\mathbf{x}}$. So, if we collect all the tangents of the feasible set X at $\bar{\mathbf{x}}$ at a feasible point $\bar{\mathbf{x}}$ and that is called the tangent set, and we are going to denote it by $T(\bar{\mathbf{x}})$. So, $T(\bar{\mathbf{x}})$ denotes the set of all tangents of the feasible region at a given point $\bar{\mathbf{x}}$.

(Refer Slide Time: 44:18)

$$\begin{aligned} \min & \quad f(\mathbf{x}) \\ \text{s.t.} & \quad e_i(\mathbf{x}) = 0, \quad i = 1, \dots, m \\ & \quad \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- $X = \{\mathbf{x} \in \mathbb{R}^n : e_i(\mathbf{x}) \leq 0, \quad i = 1, \dots, m\}$
- **Regular Point:** A point $\bar{\mathbf{x}} \in X$ is said to be a regular point if $\nabla e_i(\bar{\mathbf{x}}), \quad i = 1, \dots, m$ are linearly independent.

Now, let us see how to characterize this tangent set? If you recall for the inequality constraints, we use the feasible set f of x script f x and then, that script f x feasible set was characterized using f tilde. So, similarly, how do we characterize T_x ? So, let us look at that part. Now, so far that purpose will need the definition of a regular point. So, a point \bar{x} in the feasible set, a set to be regular point if gradient $e_i \bar{x}$ are linearly independent.

So, this definition is similar to what we saw for inequality constraints, though only difference is that for the inequality constraints, we just had to take only those inequality which we were active or for which $h_j \bar{x}$ was 0 and then, the gradient of those points have to be linearly independent while here since we are talking about the active equality constraints. All the constraints are active at any given point \bar{x} and therefore, a point \bar{x} in the feasible set is a regular point, if the gradients of all active or all equality constraints are linearly independent or gradient $e_i \bar{x}$ i going from 1 to m is a linearly independent set.

(Refer Slide Time: 46:02)

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & e_i(\mathbf{x}) = 0, \quad i = 1, \dots, m \\ & \mathbf{x} \in \mathbb{R}^n \end{aligned}$$

- $X = \{\mathbf{x} \in \mathbb{R}^n : e_i(\mathbf{x}) \leq 0, \quad i = 1, \dots, m\}$
- **Regular Point:** A point $\bar{\mathbf{x}} \in X$ is said to be a regular point if $\nabla e_i(\bar{\mathbf{x}}), \quad i = 1, \dots, m$ are linearly independent.
- At a regular point $\bar{\mathbf{x}} \in X$,

$$T(\bar{\mathbf{x}}) = \{\mathbf{d} : \nabla e_i(\bar{\mathbf{x}})^T \mathbf{d} = 0, \quad i = 1, \dots, m\}$$

NPTEL Shrish Shekhar Numerical Optimization

Now, this result will not prove these results, but use these results that at a regular point $\bar{\mathbf{x}}$, the tangent set is characterized by the set of all directions \mathbf{d} which are orthonormal to gradient $\nabla e_i(\bar{\mathbf{x}})$ which are orthonormal to the gradients of the equality constraints. So, note that we are again using all i 's going from 1 to m . That means, we are using all active or all the equality constraints, since they are active at any given feasible $\bar{\mathbf{x}}$.

(Refer Slide Time: 47:07)

- Let $\mathbf{x}^* \in X$ be a regular point and local extremum (minimum or maximum) of the problem
- Consider any $\mathbf{d} \in T(\mathbf{x}^*)$.
- Let $\mathbf{x}(t)$ be any smooth curve such that
 - $\mathbf{x}(t) \in X$
 - $\mathbf{x}(0) = \mathbf{x}^*, \quad \dot{\mathbf{x}}(0) = \mathbf{d}$
 - $\exists a > 0$ such that $e_i(\mathbf{x}(t)) = 0 \quad \forall t \in [-a, a]$
- \mathbf{x}^* is a regular point
 - $\Rightarrow T(\mathbf{x}^*) = \{\mathbf{d} : \nabla e_i(\mathbf{x}^*)^T \mathbf{d} = 0, \quad i = 1, \dots, m\}$
- \mathbf{x}^* is a constrained local extremum
 - $\Rightarrow \frac{d}{dt} f(\mathbf{x}(t))|_{t=0} = 0 \Rightarrow \nabla f(\mathbf{x}^*)^T \mathbf{d} = 0$.

If \mathbf{x}^* is a regular point w.r.t. the constraints $e_i(\mathbf{x}) = 0, \quad i = 1, \dots, m$ and \mathbf{x}^* is a local extremum point (a minimum or maximum) of f subject to these constraints, then $\nabla f(\mathbf{x}^*)$ is orthogonal to the tangent set, $T(\mathbf{x}^*)$.

NPTEL Shrish Shekhar Numerical Optimization

So, the set of all \mathbf{d} 's which are orthogonal to the gradients of the equality constraints at $\bar{\mathbf{x}}$. So, under the regularity assumptions, one can show that $T(\bar{\mathbf{x}})$ is this set and we

will use this fact to derive conditions for the local minimum of constraints problem. So, let us assume that x^* which is feasible point, also a regular point and is the local extremum. Now, note that we have mentioned here local extremum which means I can be a local minimum or a local maximum.

Now, let us consider a new vector d which is in the tangent set T_x . So, since it is a regular point, we have already seen that $\text{gradient } e_i x^* \text{ transpose } d = 0$ for all i going from 1 to m . Now, let us consider us any smooth curve in the feasible set. Let us denote that curve by $x(t)$, where t is a parameter is a real number and $x(t)$ denotes some point x in the feasible region. So, all $x(t)$'s are feasible, moreover at $t = 0$. We have $x(0) = x^*$ and then, the tangent at 0 where going to denote by d and there exists some positive a , such that $e \cdot x(t) = 0$. So, that means that around or in a close interval minus a to a , if you take any t , then $e \cdot x(t) = 0$. So, this is some set of feasible points in the neighborhood of $x(0)$ and the points are parameterized by the parameter t . Now, we have assumed that x^* is a regular point. So, that means that the tangent set at x^* which is characterized by the set of all directions which are orthogonal to the gradients of the equality, all the equality constraints.

Now, x^* is also given to be a local extremum of a given objective function subject to the constraints. So, that means that the derivative of f of $x(t)$ with respect to t evaluated at $t = 0$ because $x(0)$ is nothing, but x^* . So, these derivative is 0 and that means that $\text{gradient } f \cdot x^* \text{ transpose } d = 0$ or d is orthogonal to $\text{gradient } f \cdot x^*$. Now, we will see that we have considered any d which was from the tangent set and the tangent set is characterized by these under the regularity assumption, and if x^* is a local minimum, then this holds. So, from this we will see that $\text{gradient } f \cdot x^*$, this orthogonal to $\text{gradient } e_i x^*$ for a lies or in other words, $\text{gradient } f \cdot x^*$ is orthogonal to the tangent set T_{x^*} .

So, if x^* is a regular point with the constraints $e_i x = 0$ over i going from 1 to m and x^* is a local extremum point, whether it is a minimum or maximum, it is a local minimum of x this subject to these constraints, then $\text{gradient } f \cdot x^*$ is orthogonal to the set T_{x^*} . So, this is a very important observation that under these conditions, the gradient of the objective function is orthogonal to the tangent set T_{x^*} and tangent set T_{x^*} is nothing, but the set of all directions which are orthogonal to $\text{gradient } e_i x$

star. So, we will use this observation to derive the optimality conditions for the local minimum of an equality constraint problem.

(Refer Slide Time: 51:55)

Theorem
 Let $\mathbf{x}^* \in X$ be a regular point and be a local minimum. Then $\exists \boldsymbol{\mu}^* \in \mathbb{R}^m$ such that

$$\nabla f(\mathbf{x}^*) + \sum_{i=1}^m \mu_i^* \nabla e_i(\mathbf{x}^*) = \mathbf{0}.$$

Proof.
 Let $\mathbf{e}(\mathbf{x}) = (e_1(\mathbf{x}), \dots, e_m(\mathbf{x}))$. $\mathbf{x}^* \in X$ is a local minimum.
 $\therefore \{\mathbf{d} : \nabla f(\mathbf{x}^*)^T \mathbf{d} < 0, \nabla e(\mathbf{x}^*)^T \mathbf{d} = 0\} = \phi$.
 Let $C_1 = \{(y_1, y_2) : y_1 = \nabla f(\mathbf{x}^*)^T \mathbf{d}, y_2 = \nabla e(\mathbf{x}^*)^T \mathbf{d}\}$ and
 $C_2 = \{(y_1, y_2) : y_1 < 0, y_2 = \mathbf{0}\}$
 Note that C_1 and C_2 are convex and $C_1 \cap C_2 = \phi$.

 NIPTE
 Shrish Shekhar Numerical Optimization

Now, here is the important theorem which says that if \mathbf{x}^* which is a feasible point is also a regular point and is a local minimum, then there exists some $\boldsymbol{\mu}^*$ which is in m -dimensional space, such that gradient f at \mathbf{x}^* is a linear combination of gradient e_i at \mathbf{x}^* . Now, you would notice the difference between the necessary condition that we obtain for inequality constraints problem and the necessary condition for an equality constraint problem.

So, the important theorem says that the multipliers corresponding to this gradient e_i at \mathbf{x}^* are not constrained to be non-negative. So, μ_i^* , this comes from the space of m -dimensional space. So, this m corresponds to the set of or the number equality constraint. So, there is one multiplier associated with each equality constraint and since, all equality constraints are active, so there exists m multipliers corresponding to all the active equality constraints and gradient f at \mathbf{x}^* is written as a linear combination of gradient e_i at \mathbf{x}^* . Now, so what this means is that if we collect all active equality constraints find out their gradients, then if under the regularity assumption we can always write gradient f at \mathbf{x}^* to be linear combination of gradient e_i at \mathbf{x}^* .

So, let us look at the proof of this theorem. Now, I have combined all the constraints and write them in the form e_1 to e_m as \mathbf{e} . So, let \mathbf{e} denote the set of all equality

constraints. Now, x^* is a local minimum. So, that means that the set of all d 's, such that $\text{gradient } f \ x^* \text{ transpose } d$ is less than 0 and $\text{gradient } e \ x^* \text{ transpose } d$ equals 0 because this is a condition corresponding to the constraints, this is the condition corresponding to the objective function. So, we do not get a descend direction d which is feasible and therefore, we can write it as this condition.

Now, if we define two sets c_1 and c_2 to be all pairs $y_1 \ y_2$, note that y_2 is a vector here, where y_1 is $\text{gradient } f \ x^* \text{ transpose } d$ and y_2 is $\text{gradient } e \ x^* \text{ transpose } d$ because e is matrix. So, $\text{gradient } e \ x^* \text{ transpose } d$ is vector and then, you take another set c_2 where y_1 is less than 0 and y_2 is equal to 0. Then, you will see that this is a convex set, c_1 also is a convex set. So, c_1 and c_2 were convex set and they have an empty intersection. So, if we have two non-empty convex set which are these joint, then we saw on the result earlier, we say that there exists $(())$, which separates c_1 and c_2 . So, it makes use of this result to get this condition and we will see that in the next class.

Thank you.
