Lecture - 29
Lagrangian Saddle Point and Wolfe Dual

(Refer Slide Time: 00:34)

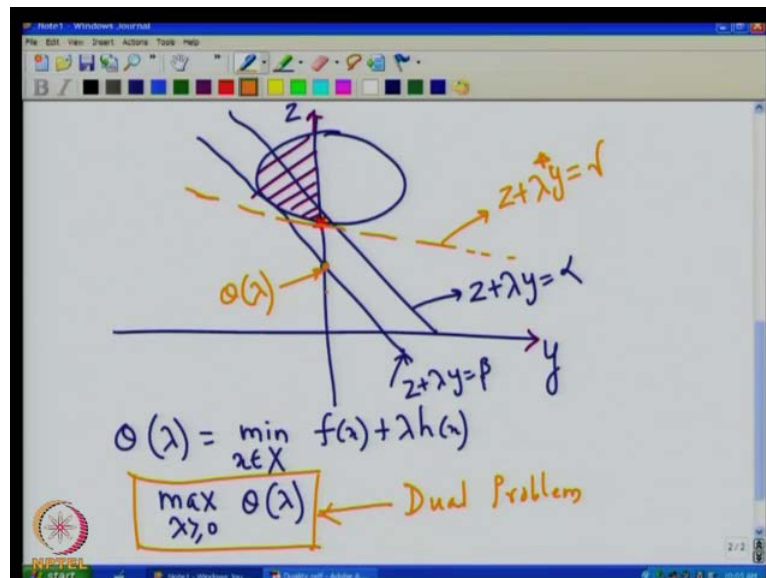

Hello, welcome back to this series of lectures on numerical optimization. In the last class we started discussing about the duality theory. And, in particular we looked at a simple problem where we want to minimize a function $f(x)$ subject to a single inequality constraint, which is $h(x)$ less than or equal to 0 and x belongs to a set X . So, we saw that in order to solve this problem; we transformed it to a another space which we called it as $y z$ space; where y is equal to $h(x)$, and z is equal to $f(x)$.

So, every point in the set X is transformed to the $y z$ space; and the corresponding set of points in the $y z$ space, suppose the points in the on or the interior of this surface. Then, we are looking at the feasible points; and then the set of feasible points is the set where y is less than or equal to 0. So, this is the set that we are interested in it. And, what we want to do is that we want to find the minimum of this problem; and that minimum of this problem is the point which is. So, this is the optimal solution to the original problem.

And, then what we did was we defined a function called theta lambda; theta lambda is a function $f(x)$ plus lambda $h(x)$. So, theta lambda is minimize x belongs to X $f(x)$ plus lambda $h(x)$, and this $f(x)$ plus lambda $h(x)$ corresponds to a line in the $y z$ space; the line z plus lambda y . Now, let us assume that lambda is nonnegative. So, it is a line with slope minus lambda.

(Refer Slide Time: 03:13)

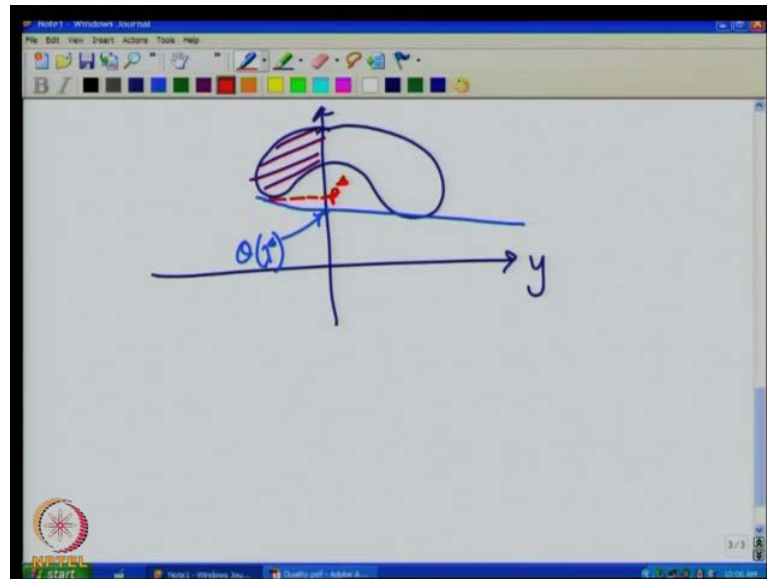

And, let us look at the picture again. So, z plus lambda y equal to constant is a line; in this space z plus lambda y is equal to alpha is a line with the slope minus lambda. Now, if you want to find out theta lambda. So, theta of lambda is nothing but minimum of $f(x)$ plus lambda $h(x)$; x belongs to X . So, for given lambda we are interested in finding out the line; which supports this feasible set from below and also touches that feasible set. So, for a given lambda we are interested in getting a line which is having the same slope; and this is z plus lambda of y is equal to beta say. So, the so the minimum value is theta lambda. Now, we have already seen that optimal objective functional value is here.

So, for a given lambda the theta lambda that we get is somewhere here; which is different from the optimal objective functional value. So, what we are interested in is finding out that lambda which is nonnegative such that the theta of lambda is maximized. So, in other words we will be interested in looking at a line, and this is z plus lambda star y is equal to gap. So, this is the line with slope minus lambda star and that is obtained by

solving this problem. And, this problem is called the dual problem. So, we are interested in finding out the dual problem. And, the reason for doing this is that many a times the dual problem is easier to solve. We will some examples in today is class about this, but it not always true that one has to always the dual problem. Because sometimes one can get a duality gap then one solves also given dual problem.

(Refer Slide Time: 06:37)

So, for example we saw another example where in the $y z$ space. If the set g is something like this and the feasible region is. So, then we will see that the minimum of this is at this point. And, if we solve the dual problem so we would get a hyper plane like this or line like this. So, this is the θ of λ star and this value is p star. So, you will see that there is some duality gap. And, therefore it is not always advisable to solve the dual problem. But in some cases it may be a good idea to solve the dual problem because it may be easier to solve. And, not only that the optimal dual value will be equal to optimal primal value. So, what are the conditions under which the duality gap is 0? So, we started looking at this question.

(Refer Slide Time: 08:02)

Primal Problem

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, j = 1, \dots, l \\ & e_i(\mathbf{x}) = 0, i = 1, \dots, m \\ & \mathbf{x} \in X \end{aligned}$$

Dual Problem

$$\begin{aligned} \max \quad & \theta(\boldsymbol{\lambda}, \boldsymbol{\mu}) \\ \text{s.t.} \quad & \boldsymbol{\lambda} \geq \mathbf{0} \end{aligned}$$

where $\theta(\boldsymbol{\lambda}, \boldsymbol{\mu}) = \min_{\mathbf{x} \in X} \mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}, \boldsymbol{\mu})$.

Let \mathbf{x}^* and $(\boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$ be optimal solutions to the primal and dual problems respectively. Let p^* and d^* be optimal primal and dual objective function values respectively.

$p^* = d^* \Rightarrow$ There is no duality gap.
Under what conditions is $p^* = d^*$?

Optimal primal and dual objective function values are same ($p^* = d^*$) if and only if $(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$ is a Lagrangian saddle point, that is, for $\mathbf{x}, \boldsymbol{\lambda} \geq \mathbf{0}$,

$$\mathcal{L}(\mathbf{x}^*, \boldsymbol{\lambda}, \boldsymbol{\mu}) \leq \mathcal{L}(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*) \leq \mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*).$$

And, we saw the first part of this theorem which says that optimal primal and dual objective function values for these problems are the same; if and only if $\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*$ is a Lagrangian saddle point. That is, the conditions for the saddle point hold; when \mathcal{L} is the Lagrangian function under consideration.

(Refer Slide Time: 08:36)

Proof.

(a)

Let $(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$ be a Lagrangian saddle point where $\mathbf{x}^* \in X$ and $\boldsymbol{\lambda}^* \geq \mathbf{0}$. Let $\boldsymbol{\lambda} \geq \mathbf{0}$.

$$\begin{aligned} \mathcal{L}(\mathbf{x}^*, \boldsymbol{\lambda}, \boldsymbol{\mu}) &\leq \mathcal{L}(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*) \\ \therefore f(\mathbf{x}^*) + \sum_{j=1}^l \lambda_j h_j(\mathbf{x}^*) + \sum_{i=1}^m \mu_i e_i(\mathbf{x}^*) \\ &\leq f(\mathbf{x}^*) + \sum_{j=1}^l \lambda_j^* h_j(\mathbf{x}^*) + \sum_{i=1}^m \mu_i^* e_i(\mathbf{x}^*) \end{aligned}$$

$\therefore \left. \begin{aligned} h_j(\mathbf{x}^*) \leq 0 \quad \forall j \\ e_i(\mathbf{x}^*) = 0 \quad \forall i \end{aligned} \right\}$ and $\mathbf{x}^* \in X \Rightarrow \mathbf{x}^*$ is primal feasible

And, we saw this proof in the last class that if $\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*$ is a Lagrangian saddle point.

(Refer Slide Time: 08:46)

Proof.(continued)

$$\mathcal{L}(\mathbf{x}^*, \boldsymbol{\lambda}, \boldsymbol{\mu}) \leq \mathcal{L}(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$$

$$\therefore \sum_{j=1}^l \lambda_j h_j(\mathbf{x}^*) + \sum_{i=1}^m \mu_i e_i(\mathbf{x}^*) \leq \sum_{j=1}^l \lambda_j^* h_j(\mathbf{x}^*) + \sum_{i=1}^m \mu_i^* e_i(\mathbf{x}^*)$$

$$\therefore \sum_{j=1}^l \lambda_j h_j(\mathbf{x}^*) \leq \sum_{j=1}^l \lambda_j^* h_j(\mathbf{x}^*) \quad (\because e_i(\mathbf{x}^*) = 0 \forall i)$$

$$\therefore 0 \leq \sum_{j=1}^l \lambda_j^* h_j(\mathbf{x}^*) \quad (\text{Letting } \lambda_j = 0 \forall j)$$

Also, $0 \geq \sum_{j=1}^l \lambda_j^* h_j(\mathbf{x}^*)$. $(\because \lambda_j^* \geq 0, h_j(\mathbf{x}^*) \leq 0 \forall j)$

$$\therefore \sum_{j=1}^l \lambda_j^* h_j(\mathbf{x}^*) = 0 \Rightarrow \lambda_j^* h_j(\mathbf{x}^*) = 0 \forall j$$

Shirish Shekhar, Numerical Optimization

Then, we showed that \mathbf{x}^* is primal feasible and then λ_j^* of \mathbf{x}^* is equal to 0.

(Refer Slide Time: 08:52)

Proof.(continued)

$(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$ is a saddle point. $\mathcal{L}(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*) \leq \mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$.
Therefore, the dual function at $(\boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$,

$$\begin{aligned} \theta(\boldsymbol{\lambda}^*, \boldsymbol{\mu}^*) &= \min_{\mathbf{x} \in X} f(\mathbf{x}) + \sum_{j=1}^l \lambda_j^* h_j(\mathbf{x}) + \sum_{i=1}^m \mu_i^* e_i(\mathbf{x}) \\ &= \min_{\mathbf{x} \in X} \mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*) \\ &= \mathcal{L}(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*) \\ &= f(\mathbf{x}^*) + \sum_{j=1}^l \lambda_j^* h_j(\mathbf{x}^*) + \sum_{i=1}^m \mu_i^* e_i(\mathbf{x}^*) \\ &= f(\mathbf{x}^*) \end{aligned}$$

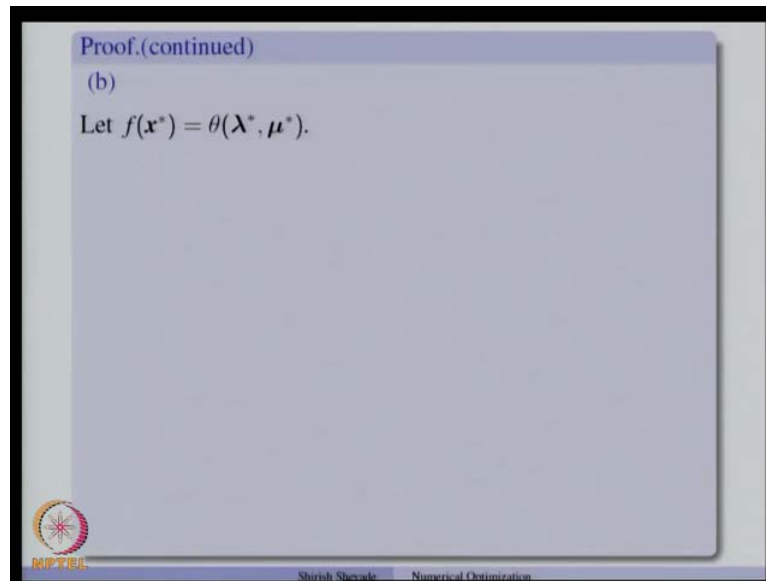

$\therefore d^* = p^*$

Shirish Shekhar, Numerical Optimization

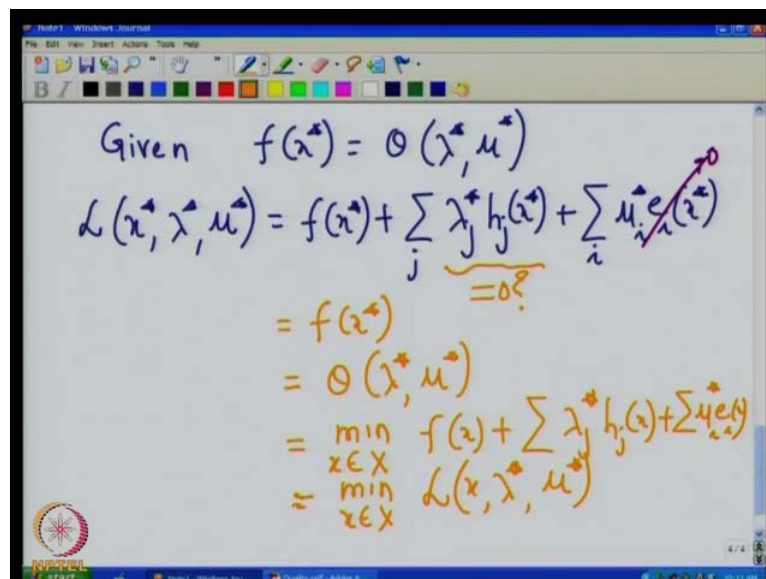

And, therefore what we get is θ of $\boldsymbol{\lambda}^*, \boldsymbol{\mu}^*$ is equal to f of \mathbf{x}^* . So, which means that there is no duality gap.

(Refer Slide Time: 09:01)

Now, we will see that the other part of the proof. Now, to prove this...

(Refer Slide Time: 09:12)

So, what is given to us is that $f(x^*)$ is equal to $\theta(\lambda^*, \mu^*)$. Of course, we assume that x^* is primal feasible such as satisfies all the primal constraints; and λ^*, μ^* satisfy all the dual constraints.

So, this is given to us. Now, we want to show that (x^*, λ^*, μ^*) is a Lagrangian saddle point. Now, if we look at $L(x^*, \lambda^*, \mu^*)$; that is nothing but $f(x^*)$ plus $\sum_j \lambda_j^* h_j(x^*)$ plus $\sum_i \mu_i^* e_i(x^*)$

star. Now, since x^* is primal feasible we can say that this quantity is 0. Now, what about this quantity? So, suppose this quantity is 0 we are not sure as of now but suppose this quantity is 0. Then, we can write this as $f(x^*)$ and what is given to us is θ of $\lambda^* \mu^*$. And, θ of $\lambda^* \mu^*$ is by definition minimize our x belongs to X $f(x)$ plus $\sum \lambda_j h_j(x)$ plus $\sum \mu_i e_i(x)$.

Now, this quantity is nothing but minimize x belongs to X the Lagrangian of x $\lambda^* \mu^*$. And, therefore we can say that L of $x^* \lambda^* \mu^*$ which is a minimum of L of $x \lambda^* \mu^*$ over x belongs to X . So, therefore L of $x^* \lambda^* \mu^*$ is less than or equal to L of $x \lambda^* \mu^*$ for all feasible x . So, the question is that can we show that λ_j^* of x^* is equal to 0? So, if we show that then one part of the saddle point conditions are satisfied. Now, similarly once we show that λ_j^* of x^* is equal to 0; then what we get is L of $x^* \lambda^* \mu^*$ is equal to f of x^* .

(Refer Slide Time: 12:28)

$$L(x^*, \lambda^*, \mu^*) = f(x^*)$$

$$\geq f(x^*) + \sum \lambda_j h_j(x^*) + \sum \mu_i e_i(x^*)$$

$$= L(x^*, \lambda^*, \mu^*)$$

So, L of $x^* \lambda^* \mu^*$ is equal to f of x^* . And, if we choose λ 's to be nonnegative then we can write this as this is nothing but which is greater than or equal to f of x^* plus $\sum \lambda_j h_j$ of x^* plus $\sum \mu_i e_i$ of x^* . Now, this quantity is 0, h_j of x^* is less than or equal to 0 and λ 's are nonnegative. So, f of x^* ; so this quantity is always less than or equal to 0. And therefore f of x^* is greater than or equal to this and this is nothing but L of $x^* \lambda^* \mu^*$. So, L of x^*

λ^* μ^* is greater than or equal to $L(x^*)$. So, both the saddle point conditions both the conditions related to the saddle point are satisfied. And, therefore we can say that under the 0 duality gap condition there exists a saddle point. So, the important thing we have to show is that $\lambda_j^* h_j(x^*) = 0$; and that is what we will show now.

(Refer Slide Time: 14:00)

Proof.(continued)

(b)

Let $f(x^*) = \theta(\lambda^*, \mu^*)$. Note that x^* is primal feasible and (λ^*, μ^*) is dual feasible. Let x be primal feasible and $\lambda_j \geq 0 \forall j$.

$$\begin{aligned} \therefore \theta(\lambda^*, \mu^*) &= \min_{x \in X} f(x) + \sum_{j=1}^l \lambda_j^* h_j(x) + \sum_{i=1}^m \mu_i^* e_i(x) \\ &\leq f(x^*) + \sum_{j=1}^l \lambda_j^* h_j(x^*) + \sum_{i=1}^m \mu_i^* e_i(x^*) \\ &= f(x^*) + \sum_{j=1}^l \lambda_j^* h_j(x^*) \\ &\leq f(x^*) \quad (\because \lambda_j^* \geq 0, h_j(x^*) \leq 0) \end{aligned}$$

But, $\theta(\lambda^*, \mu^*) = f(x^*)$. Therefore, $\lambda_j^* h_j(x^*) = 0 \forall j$.

MIT Logo | Shriniv Sharma - Nonlinear Optimization

So, note that x^* is primal feasible and $\lambda^* \mu^*$ is dual feasible. And, also let us assume that x is a primal feasible point and λ_j 's are nonnegative for all j . Now, $\theta(\lambda^*, \mu^*)$ is nothing but minimize effects subject to λ_j star; subject to x belongs to X minimize $f(x)$ plus $\sum \lambda_j^* h_j(x)$ plus $\sum \mu_i^* e_i(x)$.

And, this is less than or equal to $f(x^*) + \sum \lambda_j^* h_j(x^*) + \sum \mu_i^* e_i(x^*)$. Now, x^* is primal feasible so this quantity is 0. And, $\lambda_j^* h_j(x^*)$ of x^* is summed up for all the constraints and added to $f(x^*)$. So, this is what we get. Now, what is given to us $f(x^*)$ is equal to $\theta(\lambda^*, \mu^*)$. So, there is a strict equality in this case. So, now since λ_j^* are greater than or equal to 0 because they are dual feasible; and $h_j(x^*)$ is less than or equal to 0. This quantity is less than or equal to 0 and therefore, this is less than or equal to $f(x^*)$. Because λ_j^* is nonnegative $h_j(x^*)$ is less than or equal to 0 for all j . But we are given that $\theta(\lambda^*, \mu^*)$ is equal to $f(x^*)$. So, this quantity has to be 0.

And, therefore what we get is $\lambda_j^* h_j(x^*) = 0$ for all j . And, this is what we wanted to use.

(Refer Slide Time: 16:04)

Proof.(continued)

$$\begin{aligned} \mathcal{L}(x^*, \lambda^*, \mu^*) &= f(x^*) + \sum_{j=1}^l \lambda_j^* h_j(x^*) + \sum_{i=1}^m \mu_i^* e_i(x^*) \\ &= f(x^*) \\ &= \theta(\lambda^*, \mu^*) \\ &= \min_{x \in X} \mathcal{L}(x, \lambda^*, \mu^*) \\ \therefore \mathcal{L}(x^*, \lambda^*, \mu^*) &\leq \mathcal{L}(x, \lambda^*, \mu^*) \quad \dots (1) \end{aligned}$$

Also,

$$\begin{aligned} \mathcal{L}(x^*, \lambda^*, \mu^*) &= f(x^*) \\ &\geq f(x^*) + \sum_{j=1}^l \lambda_j h_j(x^*) + \sum_{i=1}^m \mu_i e_i(x^*) \\ \therefore \mathcal{L}(x^*, \lambda^*, \mu^*) &\geq \mathcal{L}(x^*, \lambda, \mu) \quad \dots (2) \end{aligned}$$

From (1) and (2), (x^*, λ^*, μ^*) is a Lagrangian saddle point. \square

Shrish Shekhar, Numerical Optimization

Now, one can write the Lagrangian of at x^* λ^* μ^* to be this sum and as I mentioned earlier that $e_i(x^*) = 0$, $\lambda_j^* h_j(x^*) = 0$. And, this quantity is nothing but $f(x^*)$. And, therefore we can write this as $\theta(\lambda^*, \mu^*)$ because there is no duality gap. So, $\theta(\lambda^*, \mu^*) = f(x^*)$.

And, by the definition of $\theta(\lambda^*, \mu^*)$ we have minimum $\theta(\lambda^*, \mu^*)$ to be minimum of $x \in X$, $\mathcal{L}(x, \lambda^*, \mu^*)$. And, therefore what we have what is that $\mathcal{L}(x^*, \lambda^*, \mu^*) \leq \mathcal{L}(x, \lambda^*, \mu^*)$; that is our first condition. Now, we again look at $\mathcal{L}(x^*, \lambda^*, \mu^*)$. Now, we have already shown that $\lambda_j^* h_j(x^*) = 0$ and we know that x^* is primal feasible; so this quantity is also 0. So, $\mathcal{L}(x^*, \lambda^*, \mu^*) = f(x^*)$. Now, that quantity is greater than or equal to $f(x^*) + \sum_{j=1}^l \lambda_j h_j(x^*) + \sum_{i=1}^m \mu_i e_i(x^*)$ because this quantity is anyway 0.

And, remember that $\lambda_j^* \geq 0$ and $h_j(x^*) \leq 0$. So, $\lambda_j^* h_j(x^*) = 0$. So, $f(x^*)$ is always greater than or equal to this quantity; and this quantity is nothing but $\mathcal{L}(x^*, \lambda, \mu)$. So, we have got another condition we show that $\mathcal{L}(x^*, \lambda, \mu) \leq \mathcal{L}(x^*, \lambda^*, \mu^*)$.

star mu star is greater than or equal to L of x star lambda mu. Now, if you combine 1 and 2; we can see that x star lambda star mu star is a Lagrangian saddle point.

(Refer Slide Time: 17:54)

How to find a saddle point if it exists?
 Consider the problem (NLP):

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & e_i(\mathbf{x}) = 0, \quad i = 1, \dots, m \\ & \mathbf{x} \in X \end{aligned}$$

Theorem
 Let f and h_j 's be continuously differentiable convex functions, $e_i(\mathbf{x}) = \mathbf{a}_i^T \mathbf{x} - b_i \forall i$ and X be a convex set. Assume that Slater's condition holds. Then,
 $(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$ is a KKT point $\Rightarrow (\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$ is a Lagrangian saddle point.

If \mathbf{x}^* is primal feasible, $\mathbf{x}^* \in \text{int}(X)$, $\boldsymbol{\lambda}^*$ is dual feasible and $(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$ is a Lagrangian saddle point, then $(\mathbf{x}^*, \boldsymbol{\lambda}^*, \boldsymbol{\mu}^*)$ is a KKT point.

Shrish Shevade Numerical Optimization

Now, so far we have shown that there is no duality gap if and only if there exists a Lagrangian saddle point. But how do we find out saddle a saddle point if such a point exists?

Because it is very difficult to check the saddle point conditions. So, is there any better way of ensuring the existence of saddle and finding it out. So, let us consider a general non-linear programming problem; there be a minimize effects subject to the set of inequality constraints and the set of equality constraints. Now, under certain convexity assumptions one can show that the KKT point is a Lagrangian saddle point. And, KKT points as we saw in one of the earlier classes there easy to check. So, here we have another important theorem which states if f and h_j x are continuously differentiable convex functions.

So, the objective function is convex the functions associated with the inequality constraints of the type $h_j(x)$ less than or equal to 0. So, the function $h_j(x)$ are all convex and the function $e_i(x)$ are affine functions. So, in other words $e_i(x)$ is nothing but a $\mathbf{a}_i^T \mathbf{x} - b_i$. And, assume that X is also convex set. So, we have a convex programming problem. So this is no longer a general non-linear program, but it is a convex programming problem. There we want to minimize a convex function subject to

a convex set. And, it is clear that this set is convex set because it is a intersection of all convex sets.

Now, we also assume that latest condition holds. So, that means that it the constraint set has nonempty interior; the constraint set is convex and has nonempty interior. Then, the first result says that if x^* λ^* μ^* is a KKT point; then x^* λ^* μ^* is a Lagrangian saddle point. And, the second result says that if x^* is primal feasible and it belongs to the interior of the set X and λ^* is dual feasible. And, x^* λ^* μ^* is a Lagrangian saddle point then x^* λ^* μ^* is a KKT point.

So, under certain convexity assumptions and the Slater's constraint qualification condition a KKT point is a Lagrangian saddle point. And, therefore for such problems the duality gap does not exist. And, it is sometimes easy to solve the dual problem rather than the primal problem. So, we will first study the proof of this theorem and then later or we will see some examples related to this conditions. So, the first part of the proof is about proving that a KKT point under the convexity assumptions is a saddle point. So, let us look at that condition that proof.

(Refer Slide Time: 21:36)

Proof.

x^* is primal feasible. $\therefore h_j(x^*) \leq 0 \forall j$ and $e_i(x^*) = 0 \forall i$.
 (x^*, λ^*, μ^*) is a KKT point. Therefore,

$$\nabla f(x^*) + \sum_{j=1}^l \lambda_j^* \nabla h_j(x^*) + \sum_{i=1}^m \mu_i^* \nabla e_i(x^*) = \mathbf{0}$$

$$\lambda_j^* h_j(x^*) = 0 \forall j$$

$$\lambda_j^* \geq 0 \forall j$$

f is convex. Therefore, for all $x \in X$,

$$f(x) \geq f(x^*) + \nabla f(x^*)^T (x - x^*). \quad \dots (3)$$

Similarly, since every h_j is convex,

$$h_j(x) \geq h_j(x^*) + \nabla h_j(x^*)^T (x - x^*). \quad \dots (4)$$

Every e_i is an affine function. Therefore,

$$e_i(x) = e_i(x^*) + \nabla e_i(x^*)^T (x - x^*). \quad \dots (5)$$

NPTEL

So, we assume that x^* is primal feasible. Therefore, satisfies all the inequality and equality constraints. And, of course, x^* belongs to the set X . Now, we are given that x^* λ^* μ^* is a KKT point. So, it has to satisfy 3 conditions along with the

feasibility conditions. So, the first condition is that the gradient of the Lagrangian should vanish at x^* , λ^* , μ^* . The gradient which is evaluated with respect to x . So, gradient of the Lagrangian is $\text{gradient } f \text{ of } x^* + \sum \lambda_j^* \text{gradient } h_j \text{ of } x^* + \sum \mu_i^* \text{gradient } e_i \text{ of } x^*$.

And, that should be equal to 0. And, second condition is about the complimentary slackness condition. So, $\lambda_j^* h_j(x^*) = 0$ for all j . And, other condition is that all the Lagrangian multipliers λ_j^* are nonnegative. Now, these conditions along with the feasibility ensure that the KKT's conditions are satisfied by x^* , λ^* , μ^* . Of course, we are assuming that x^* also belongs to set X ; that is part of the primal feasibility. Now, we make use of the convexity of the functions f , h and the affinity of the function e_i . And, use those conditions to derive that x^* , λ^* , μ^* is indeed a saddle point.

So, let us look at the function f . Now, f being a convex function we have already seen in one of the earlier classes; that an affine approximation of a convex function at any point does not over estimate the function. So, since f is convex we saw this result earlier that $f(x)$ for every x in the feasible set X $f(x)$ is greater than or equal to $f(x^*) + \text{gradient } f \text{ of } x^* \text{ transpose } (x - x^*)$. So, the right side is an affine approximation of the function at x^* . And, we know that that does not over estimate the function. Now, the same result can be applied to the convex functions related to the inequality constraint. That is the function $h_j(x)$ less than or equal to the constraints $h_j(x)$ less than or equal to 0 and the associated functions are $h_j(x)$. So, for every $h_j(x)$ which is a x which is a convex function $h_j(x)$ is again greater than or equal to $h_j(x^*) + \text{gradient } h_j \text{ of } x^* \text{ transpose } (x - x^*)$. Now, e_i as affine function. Therefore, we can write $e_i(x)$ equal to $e_i(x^*) + \text{gradient } e_i \text{ of } x^* \text{ transpose } (x - x^*)$.

Now, remember that we want to find out the conditions associated with the Lagrangian saddle point. So, the Lagrangian saddle point is nothing but I am sorry the Lagrangian function $L(x, \lambda, \mu)$ is nothing but $f(x) + \sum \lambda_j h_j(x) + \sum \mu_i e_i(x)$. So, in order to get towards those conditions what we need to is that we need to multiply this equation; equation 4 by λ_j and equation 5 by μ_i . Then, sum them up and the same exercise has to be done in the right side. Since, λ_j 's are nonnegative; the inequality sign inequality direction does not change. So, even if you multiply λ_j throughout the inequality same inequality holds. And, this is an equality

and $\mu_i e_i$ is an affine function and μ_i is unrestricted in sign. So, we can multiply μ_i by e_i both sides and then we add up the left hand side as well as the right hand side.

Now, when we add the right side in the first term what we get is $f(x^*) + \sum_{j=1}^l \lambda_j^* h_j(x^*) + \sum_{i=1}^m \mu_i^* e_i(x^*)$. Now, if we multiply by λ_j^* and μ_i^* . Then, what we get is $\lambda_j^* \text{gradient } h_j \text{ of } x^*$ plus $\mu_i^* \text{gradient } e_i \text{ of } x^*$; and that quantity is 0 because of this condition. So, if you multiply second by λ_j^* and equation 4 by λ_j^* and equation 5 by μ_i^* . Then, this quantity the second terms vanish.

(Refer Slide Time: 27:24)

Proof. (continued)

Multiplying (4) by λ_j^* and (5) by μ_i^* , adding and using KKT conditions,

$$f(x) + \sum_{j=1}^l \lambda_j^* h_j(x) + \sum_{i=1}^m \mu_i^* e_i(x) \geq f(x^*) + \sum_{j=1}^l \lambda_j^* h_j(x^*) + \sum_{i=1}^m \mu_i^* e_i(x^*)$$

$$\therefore \mathcal{L}(x, \lambda^*, \mu^*) \geq \mathcal{L}(x^*, \lambda^*, \mu^*) \quad \dots (6)$$

Also, $f(x^*) = f(x^*) + \sum_{j=1}^l \lambda_j^* h_j(x^*) + \sum_{i=1}^m \mu_i^* e_i(x^*)$

$$\geq f(x^*) + \sum_{j=1}^l \lambda_j h_j(x^*) + \sum_{i=1}^m \mu_i e_i(x^*)$$

$$\therefore \mathcal{L}(x^*, \lambda^*, \mu^*) \geq \mathcal{L}(x^*, \lambda, \mu) \quad \dots (7)$$

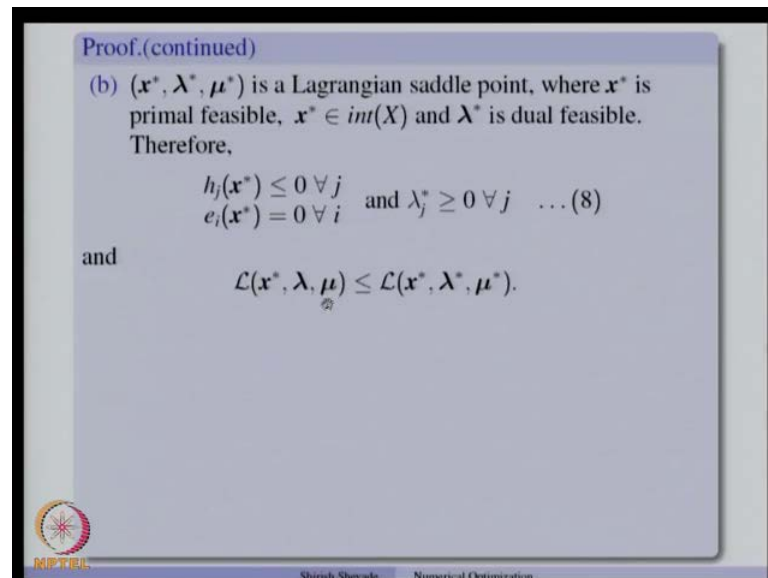

Therefore, (x^*, λ^*, μ^*) is a Lagrangian saddle point.

Shrinath Shrivastava Numerical Optimization

And, then what we are left with is the following $f(x) + \sum_{j=1}^l \lambda_j^* h_j(x) + \sum_{i=1}^m \mu_i^* e_i(x)$. So, that is the first part and that is greater than or equal to $f(x^*) + \sum_{j=1}^l \lambda_j^* h_j(x^*) + \sum_{i=1}^m \mu_i^* e_i(x^*)$. And, then the quantity corresponding to the second term vanishes because of this conditions. Now, we can use this condition further to remove this quantity and the feasibility of x^* to remove this quantity. So, what we are left with is $f(x^*) + \sum_{j=1}^l \lambda_j^* h_j(x^*) + \sum_{i=1}^m \mu_i^* e_i(x^*)$ is greater than or equal to μ_i^* . Now, $f(x^*)$ is nothing but $f(x^*) + \sum_{j=1}^l \lambda_j^* h_j(x^*) + \sum_{i=1}^m \mu_i^* e_i(x^*)$ because this is 0. And, the complimentary slackness condition give this quantity as 0. And, this quantity is greater than or equal to $f(x) + \sum_{j=1}^l \lambda_j^* h_j(x) + \sum_{i=1}^m \mu_i^* e_i(x)$.

And, therefore what we have is $L(x^*, \lambda^*, \mu^*) \geq L(x^*, \lambda^*, \mu)$. And, using these 2 conditions we can say that (x^*, λ^*, μ^*) is a Lagrangian saddle point. So, this was the first part of the theorem. Now, the second part says that if we are given a Lagrangian saddle point in the x^* is in interior then the KKT conditions are satisfied. So, in other words we have to show that this hold.

(Refer Slide Time: 29:11)

Proof.(continued)

(b) (x^*, λ^*, μ^*) is a Lagrangian saddle point, where x^* is primal feasible, $x^* \in \text{int}(X)$ and λ^* is dual feasible. Therefore,

$$\begin{aligned} h_j(x^*) &\leq 0 \quad \forall j \\ e_i(x^*) &= 0 \quad \forall i \end{aligned} \quad \text{and} \quad \lambda_j^* \geq 0 \quad \forall j \quad \dots (8)$$

and

$$\mathcal{L}(x^*, \lambda, \mu) \leq \mathcal{L}(x^*, \lambda^*, \mu^*).$$

Shrinivasa Shivakumar - Nonlinear Optimization

So, we assume that (x^*, λ^*, μ^*) is saddle point and x^* is primal feasible. So, that means $h_j(x^*) \leq 0$, $e_i(x^*) = 0$, for all j 's and i then x^* belongs to interior of the set X .

This is the assumption that we are making and λ^* is dual feasible. Now, x^* is primal feasible. So, the feasibility conditions for the primal are satisfied λ^* is dual feasible. So, feasibility conditions for the dual are satisfied. Remember that the Lagrangian multipliers corresponding to the equality constraints are unrestricted in sign. Now, (x^*, λ^*, μ^*) is also Lagrangian saddle point. And, therefore one of the conditions of the saddle point is $L(x^*, \lambda^*, \mu) \leq L(x^*, \lambda^*, \mu^*)$. Now, if you expand this so, the and cancelling the $f(x^*)$ term; what we get is something like this. Now, using the same logic that we use in the previous proof we will we can show that $\lambda_j h_j(x^*) = 0$. And, therefore 1 of the KKT conditions is satisfied.

So, λ_j^* is greater than or equal to 0 because it is dual feasible; primal feasibility is satisfied x^* belongs to the interior (X). And, we also shown the complimentary slackness condition. Now, $L(x^*, \lambda^*, \mu^*)$ is less than or equal to $L(x^*, \lambda^*, \mu^*)$ because of the saddle point conditions. And, therefore x^* is obtained by minimizing the right side function $L(x^*, \lambda^*, \mu^*)$ with respect to x belongs to X . So, the x^* is nothing but argmin mean of x and the objective function is the Lagrangian where λ^*, μ^* are kept fixed.

(Refer Slide Time: 31:25)

Proof.(continued)

$$\therefore x^* = \underset{x \in X}{\operatorname{argmin}} \mathcal{L}(x, \lambda^*, \mu^*)$$

Note that,

$$\mathcal{L}(x, \lambda^*, \mu^*) = f(x) + \sum_{j=1}^l \lambda_j^* h_j(x) + \sum_{i=1}^m \mu_i^* e_i(x).$$

$\mathcal{L}(x, \lambda^*, \mu^*)$ is a *convex* function of x (since f and h_j 's are convex functions, e_i 's are affine functions and $\lambda_j^* \geq 0$). Further, $x^* \in \operatorname{int}(X)$.

$$\therefore \nabla_x \mathcal{L}(x^*, \lambda^*, \mu^*) = \mathbf{0} \quad \dots (10)$$

Therefore, from (8), (9) and (10), we see that (x^*, λ^*, μ^*) is a KKT point. \square

NPTTEL

Now, $L(x^*, \lambda^*, \mu^*)$ this quantity if we expand it so, we have $f(x)$ plus $\sum \lambda_j^* h_j(x)$ plus $\sum \mu_i^* e_i(x)$. Now, $f(x)$ is a convex function, $h_j(x)$ is a convex function, λ_j^* are nonnegative, $e_i(x)$ is an affine function. That is the problem that we are considering and μ_i^* are unrestricted in sign. So, since $e_i(x)$ is affine function $f(x)$ is convex and $h_j(x)$ is also a convex function λ_j^* nonnegative; this function is a convex function. So, $L(x^*, \lambda^*, \mu^*)$ is a convex function.

And, x^* is the minimum of that convex function over the set x and we have assume that x^* lies in the interior. So, the minimum of a convex function lies in the interior means that the gradient of the convex function L should vanish at x^* . So, in other words gradient of L evaluated with respect to x and evaluated at x^*, λ^*, μ^* is equal to 0. And, this was 1 of the KKT conditions that we wanted to prove

because we had already proven the complimentary slackness conditions. And, we knew that λ_j^* is we assume that λ_j^* are dual feasible. So, they are nonnegative and x^* is primal feasible. And, therefore all the conditions KKT conditions are satisfied. And, therefore $x^* \lambda^* \mu^*$ is a KKT point.

And, this was possible because of the assumption that x^* belongs to the interior of the set x and L is the convex function over the convex set x . So, this theorem has important implication. And, that this theorem gives us an idea about how to write the dual problem of a given convex programming problem?

(Refer Slide Time: 34:01)

Consider the convex programming problem (CP):

$$\begin{aligned} \min \quad & f(x) \\ \text{s.t.} \quad & h_j(x) \leq 0, \quad j = 1, \dots, l \\ & e_i(x) = 0, \quad e_i(x) = a_i^T x - b_i, \quad i = 1, \dots, m \\ & x \in \mathbb{R}^n \end{aligned}$$

where f and h_j 's are continuously differentiable convex functions. Assume that Slater's condition holds.

$$\mathcal{L}(x, \lambda, \mu) = f(x) + \sum_{j=1}^l \lambda_j h_j(x) + \sum_{i=1}^m \mu_i e_i(x)$$

Dual Problem : $\max_{\lambda \geq 0, \mu} \min_{x \in \mathbb{R}^n} \mathcal{L}(x, \lambda, \mu)$

which is the **Wolfe Dual** of CP:

$$\begin{aligned} \max_{x, \lambda, \mu} \quad & \mathcal{L}(x, \lambda, \mu) \\ \text{s.t.} \quad & \nabla_x \mathcal{L}(x, \lambda, \mu) = 0 \\ & \lambda \geq 0 \end{aligned}$$

NPTL Shrish Shekhar Numerical Optimization

So, let us consider a convex programming problem; where f is a convex function. The objective function is convex the constraint the inequality constraints are $h_j(x)$ less than or equal to 0. And, the function $h_j(x)$ corresponding to these inequality constraints is also a convex function; the equality constraints are given by $a_i^T x - b_i$ equal to 0. And, let us consider the set x to be entire set \mathbb{R}^n .

Let us also assume the differentiability of f and h and they are also convex. Let us assume that the constraint set finally that we get is also such that it has nonempty interior. So, which means that Slater's condition holds. So, the Lagrangian which is a convex function (x) is $f(x)$ plus sigma $\lambda_j h_j(x)$ plus sigma $\mu_i e_i(x)$. And, the dual problem is a max min problem; where we minimize the Lagrangian with respect to x belongs to \mathbb{R}^n . And, then that function is maximize with respect to λ 's which are

nonnegative and μ which are unrestricted in sign. Now, if you look at this problem minimize x belongs to \mathbb{R}^n $L(x, \lambda, \mu)$.

Since, L is a convex function which we saw earlier. So, the minimum at the minimum of this gradient of the Lagrangian with respect to x should vanish. Therefore, the dual problem becomes maximum maximize $L(x, \lambda, \mu)$ subject to the constraint that the gradient of the Lagrangian evaluated with respect to x vanishes; and λ 's are dual feasible. So, this problem is called the Wolfe dual problem. Wolfe was the first person to show that for convex programming problems under this constraint qualification condition. I can write the dual in a simple form which is maximize the Lagrangian subject to the constraint at the gradient of the Lagrangian with respect to the primal variable vanishes.

And, the λ 's the Lagrangian multipliers are associated with the inequality constraint of the type $h_j(x) \leq 0$ are nonnegative. Now, these 2 problems the original CP and the dual problem CP under the assumption of constraint qualification or Slater's condition have the same optimal solution. So, in other words these 2 problems are equivalent to each other. So, one can either solve this problem or this problem and I would get the same optimal solution or in other words there is no duality gap.

But then I may wonder that this was the problem with respect to x ; here we have introduced more variables λ and μ . And, therefore this problem may be more difficult to solve compared to the original problem. But as we will see some examples you will realize that the dual problem is many a times here the Wolfe dual problem is many a times easier to solve compared to the primal problem. Although there is no rule that every time one has to solve the dual problem; but sometimes the it becomes easier to solve the dual problem than the primal. Because some of these variables get eliminated and some of the constraints also get eliminated. And, we are left with the simple problem than the original primal problem. So, we will look at some examples.

(Refer Slide Time: 38:15)

Example:

$$\begin{aligned} \min & (x-2)^2 \\ \text{s.t.} & 2x+1 \leq 0 \\ & x \in [-1, 1] \end{aligned}$$

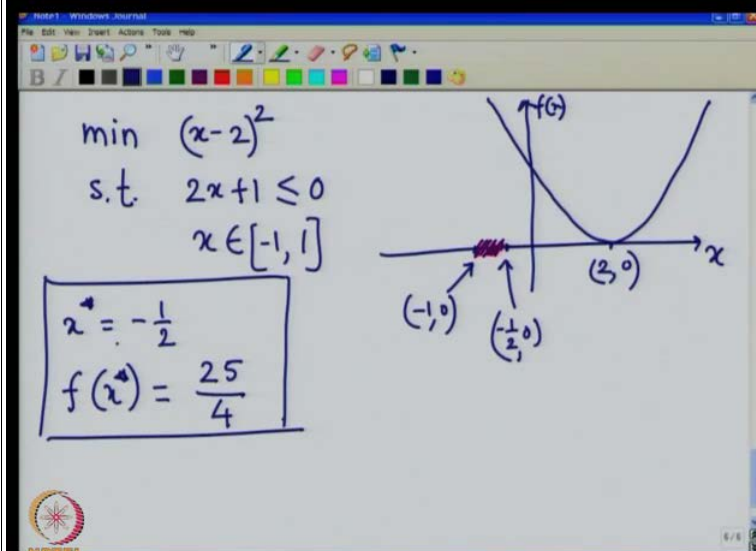

- Convex Programming Problem
- Slater's condition holds

Shreshth Shrivastava Numerical Optimization

So, this is an example to minimize a 1 dimensional function x minus 2 square subject to the constraint that $2x$ plus 1 less than or equal to 0 and x belongs to minus 1 to 1. So, this interval minus 1 to 1 becomes our constraint set x which is the constraint $h(x)$ less than or equal to 0 and this is the objective function. Now, you will see that the objective function is the convex function. This constraint set is a convex set and this constraint set is also convex set. So, the intersection of the convex sets is also convex set. So, we have a convex programming problem and this also satisfies Slater's condition. Now, let us solve this problem.

(Refer Slide Time 39:29)

$$\begin{aligned} \min & (x-2)^2 \\ \text{s.t.} & 2x+1 \leq 0 \\ & x \in [-1, 1] \end{aligned}$$

$$\boxed{\begin{aligned} x^* &= -\frac{1}{2} \\ f(x^*) &= \frac{25}{4} \end{aligned}}$$

The graph shows a parabola $f(x) = (x-2)^2$ with its vertex at $(2, 0)$. The feasible region is the interval $x \in [-1, 1]$, which is shaded in red. The minimum value of the function over this interval is at $x = -1/2$, where $f(x) = 25/4$. The point $(-1, 0)$ is also marked on the x-axis.

Shreshth Shrivastava Numerical Optimization

So, we have the problem minimize $x^2 - 2x$ subject to $2x + 1 \leq 0$ and $x \in [-1, 1]$. Now, let us see the graph of the function. So, the objective function is a function like this which has 0 at this point; the function value 0 at this point. Now, let us look at the constraints. So, the first constraint says that x is less than or equal to minus half. And, that would be somewhere here and x belongs to minus 1 to 1. So, in other words we are interested in this constraint set which is the interval from minus 1 to half.

So, we are interested in finding the minimum of this function over this interval which is shown here by shaded lines. Now, it is clear from this figure that minimum of the function will occur at $x^* = -\frac{1}{2}$. And, the corresponding value of the objective function $f(x)^*$ will be $-\frac{1}{4} - 2 \cdot (-\frac{1}{2}) = \frac{3}{4}$. So, this is our primal objective function and this is the solution to this problem. Now, let us write down the dual problem. And, see how the dual can be solved?

(Refer Slide Time 42:09)

The image shows a handwritten derivation of the dual function in a Notepad window. The text is as follows:

$$\text{Dual function:}$$

$$\theta(\lambda) = \min_{x \in [-1, 1]} (x-2)^2 + \lambda(2x+1)$$

Differentiating w.r.t. x
& equating to 0,

$$2(x-2) + 2\lambda = 0$$

$$\therefore x^* = -\lambda + 2 \quad \text{if } \lambda \in [1, 3]$$

$$\therefore \theta(\lambda) = \lambda^2 - 2\lambda^2 + 5\lambda = -\lambda^2 + 5\lambda \quad \text{if } \lambda \in [1, 3]$$

So, let us look at the dual function. So, dual function is a function $\theta(\lambda)$ which minimizes $x^2 - 2x$ which is in the interval minus 1 to 1 $x^2 - 2x$ plus $\lambda(2x + 1)$. That is the objective function and λ into the constraint and the constraint this $2x + 1$. Now, this function is a quadratic function in x . In fact it is convex because the coefficient of x^2 is positive here. So, we differentiate this function with respect to x and equate it to 0. So, differentiating with respect to x and equating to 0, what we get is $2(x - 2) + 2\lambda = 0$.

2 plus 2 lambda is equal to 0 and from that we can get x star. And, therefore x star to be minus lambda plus 2.

Now, remember that x has to be in the interval minus 1 to 1. So, in order that x has to be in the interval minus 1 to 1. So, which means that x star also has to be in this interval we have to set a range for lambda. So, the lambda should belong to since x star belongs to minus 1 minus 1 to 1 lambda should belong to the interval 1 to 3. So, this will make sure that x star also lies in this interval. And, if we substitute this x star here what we get is so therefore, theta lambda theta lambda will be equal to substitute this value here. So, what we get is lambda square and then minus 2 lambda square plus 5 lambda. And, this is nothing but minus lambda square plus 5 lambda. If lambda belongs to the interval 1 to 3 so we have got theta lambda. So, now the dual problem.

(Refer Slide Time 45:25)

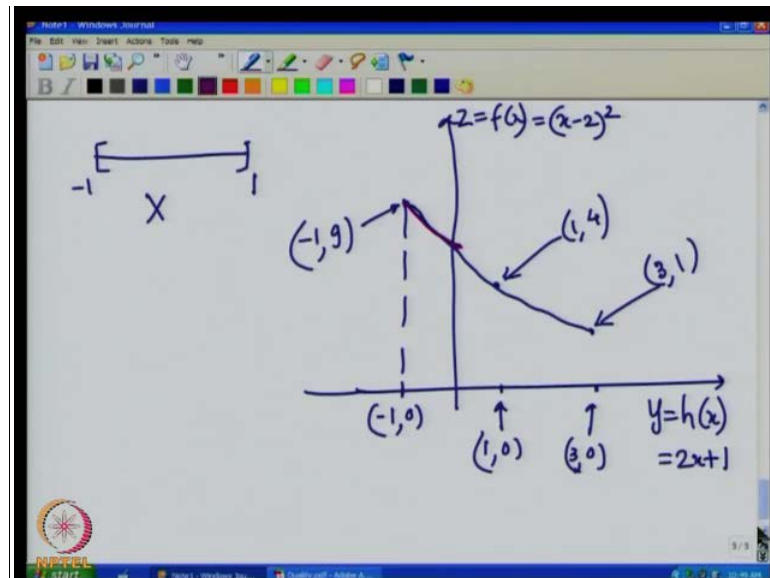

The image shows a whiteboard with handwritten mathematical work. At the top, it says "Dual Problem:". Below that, the optimization problem is written as:
$$\max_{\lambda \in [1, 3]} Q(\lambda) \equiv \max_{\text{s.t. } \lambda \in [1, 3]} -\lambda^2 + 5\lambda$$
Then, the derivative is set to zero:
$$-2\lambda + 5 = 0 \Rightarrow \lambda = \frac{5}{2}$$
Finally, the optimal value is calculated and boxed:
$$\therefore d^* = \frac{-25}{4} + \frac{25}{2} = \frac{25}{4}$$
The whiteboard also shows a toolbar at the top and a logo for NPTEL in the bottom left corner.

The dual problem is maximize theta lambda with respect to lambda which is in the interval 1 to 3, and this nothing but maximize minus lambda square plus 5 lambda; subject to lambda belongs to 1 to 3. Now, this is a concave function. So, again we differentiate this function with respect to lambda equate it to 0. And, what we get is minus 2 lambda plus 5 equal to 0 and which gives lambda is equal to 5 by 2.

So, therefore, the dual objective function value d star which should be we plug-in this 5 by 2 in the objective function. And, what we get is minus 25 by 4 plus 25 by 2 and which is nothing but 25 by 4. Now, if we compare this dual objective function value with the

primal objective function value that we got which is nothing but $f(x)$ star. We see that this dual objective function value and primal objective function values are the same. Now, with respect to the $y-z$ space what happens? So, let us look at that.

(Refer Slide Time 47:21)

So, this is the $y-z$ space that we have. So, z is nothing but $f(x)$ and y is nothing but $h(x)$. Now, $h(x)$ is nothing but $2x + 1$ and $f(x)$ is nothing but the given objective function which is x minus 2 square. So, set x is the interval minus 1 to 1. Now, this interval we take each value of x from this interval and map it to the $y-z$ space. So, we get a curve like this. So, in other words when x equal to minus 1. So, this that is the quantity which is here minus 1. And, then when x equal to minus 1 what we get is 9. So, this point which corresponds to (No Audio From 49:01 to 49:09) so this point is minus 1, 9. When x equal to 0 y is 1. So, this is this quantity this point in the $y-z$ space; and when x is 0 this is 4. So, this is 1 4; and when x is 1 y is 3 and z is 1. So, we get a function like this and what we are interested in is y less than or equal to 0.

So, we are interested in only this part of the function. Now, if we take a line which supports this feasible set from below. Then, that line will have slope which is minus 5 by 2. And, moreover as we saw earlier that the optimal primal and dual objective function values are same. And, therefore there is no duality gap.

(Refer Slide Time 50:57)

Example:

$$\begin{aligned} \min \quad & (x-2)^2 \\ \text{s.t.} \quad & 2x+1 \leq 0 \\ & x \in [-1, 1] \end{aligned}$$

- Convex Programming Problem
- Slater's condition holds
- $x^* = -\frac{1}{2}$, $p^* = f(x^*) = \frac{25}{4}$
- Dual function: $\theta(\lambda) = \min_{x \in [-1, 1]} (x-2)^2 + \lambda(2x+1)$

The Wolfe dual problem is:

$$\begin{aligned} \max \quad & -\lambda^2 + 5\lambda \\ \text{s.t.} \quad & \lambda \in [1, 3] \end{aligned}$$

Solution: $\lambda^* = \frac{5}{2}$

Optimal Dual Objective Value, $d^* = \frac{25}{4} = p^*$

Shrish Shekhar, Numerical Optimization

So, the dual function is minimize x minus 2 square plus lambda 2 x plus 1. And, therefore the Wolfe dual problem is maximize minus lambda square plus 5 lambda and lambda belongs to the close interval 1 to 3. And, therefore by solving this we get lambda star to be 5 by 2. And, the optimal objective function and for the dual problem; which is 25 by 4 is same as the optimal objective function value for the primal problem. Now, look at another example.

(Refer Slide Time 51:33)

Example:

Consider the problem:

$$\begin{aligned} \min \quad & x_1^2 + x_2^2 + \dots + x_n^2 \\ \text{s.t.} \quad & x_1 + x_2 + \dots + x_n = 1 \end{aligned}$$

- Convex programming problem
- Slater's condition holds
- $\mathbf{x}^* = (\frac{1}{n}, \dots, \frac{1}{n})^T$, $f(\mathbf{x}^*) = \frac{1}{n}$
- $\mathcal{L}(\mathbf{x}, \mu) = x_1^2 + \dots + x_n^2 + \mu(x_1 + \dots + x_n - 1)$
- $\nabla_{\mathbf{x}} \mathcal{L}(\mathbf{x}, \mu) = \mathbf{0} \Rightarrow x_i = -\frac{\mu}{2} \forall i$

Wolfe dual problem:

$$\left. \begin{aligned} \max \quad & \mathcal{L}(\mathbf{x}, \mu) \\ \text{s.t.} \quad & \nabla_{\mathbf{x}} \mathcal{L}(\mathbf{x}, \mu) = \mathbf{0} \end{aligned} \right\} \equiv \max_{\mu \in \mathbb{R}} \frac{n}{4} \mu^2 - \mu$$

Solution to the dual problem: $\mu^* = -\frac{2}{n} \Rightarrow x_i^* = \frac{1}{n} \forall i$

Shrish Shekhar, Numerical Optimization

So, we have a problem to minimize $\|x\|^2$ subject to the constraint that $x_1 + x_2 + \dots + x_n = 1$. This is a convex programming problem because the objective function is convex the constraint set is affine. So, Slater's conditions are automatically satisfied. Now, we can see that the solution to this problem is that all values of the coordinates are the same and they are $1/n$. And, the optimal objective function value is $1/n$.

Now, let us look at the Lagrangian. So, Lagrangian is nothing but the objective function plus μ times the constraint; this μ is associated with this equality constraint. Now, we can write the Wolfe dual of this problem; so one of the conditions that is used in the Wolfe dual is that the gradient of the Lagrangian with respect to the primal variable is 0. And, this implies that $x_i = -\mu/2$. Now, if we plug-in $x_i = -\mu/2$ in this Lagrangian. Then, we can write the dual problem Wolfe dual problem as maximize the Lagrangian with respect to the constraint that the gradient of the Lagrangian with respect to x vanishes.

Now, note that μ is associated with the equality constraint. Therefore, there are no sign restrictions on μ . Now, by plugging-in in this value of x_i which is equal to $-\mu/2$; in this Lagrangian we get a function which is $-n\mu^2/4 - \mu$. Now, what is the advantage of writing the Wolfe dual? So, you will see that the Wolfe dual problem is a 1 dimensional optimization problem in this case. In fact it is an unconstrained optimization problem. So, the original n dimensional constraint optimization problem which had some nice properties that like it is a convex programming problem and Slater's condition are satisfied. So, such a n dimensional optimization problem we were able to convert it to a 1 dimensional unconstrained optimization problem.

And, not only is that because of the condition because of the results that we saw earlier for such problems the duality gap is 0. Because the KKT point is a Lagrangian saddle point and therefore, the duality gap is 0. We can solve this problem and get a solution to this problem. Now, this is an unconstrained optimization problem in μ . So, if we differentiate the objective function is convex in terms of μ . So, if we differentiate this objective function with respect to μ and equate it to 0; what we get is $\mu^* = -2/n$. Now, if you plug-in this value of μ^* in this what we get is $x^* = 1/n$.

And, that is same as this. So, this is a very important example in the sense that it gives us some idea about the advantage of solving the dual problem. In some practical situations the original problem could be an infinite dimension problem; where the norm is defined in that infinite dimensional space. And, solving an infinite dimensional problem is very difficult but in that case if we can convert the problem into a dual problem. It may so happen like in this case that the dual problem is still with respect to number of variables in dual problem is still very small and manageable. And, in that process we will not lose anything because the optimal primal and dual objective function values are same. Because of the existence of Lagrangian saddle point or for the convex programming problems the KKT point and the Lagrangian saddle points are the same. If the Slater's condition qualification holds.

So, from this example we can see that there is some advantage in solving the in writing the dual problem of the convex programming problem. Of course, most of this results for convex programming problem. For general non-linear programming problem but dual problem may not be equal to the primal problem and there could be a duality gap. And, therefore, when 1 applies duality ideas 1 has to be careful about the convexity and the constraint qualification conditions that we discussed today. So, we will see some examples in the next class. In the last class we were discussing about Wolfe dual. And, in particular we consider this problem that we want to minimize $x_1^2 + x_2^2 + \dots + x_n^2$ subject to the constraint that $x_1 + x_2 + \dots + x_n = 1$.

So, this was the problem that we were considering last time. And, we saw that this is also a convex programming problem and Slater's condition holds good. And, we usually see that the solution is a point where every coordinate is $1/n$ and the optimal objective function value is $1/n$. So, to write the Wolfe dual we need a Lagrangian. So, which is defined as the objective function plus μ time the constraint function; and the gradient of the Lagrangian with respect to x equal to 0 implies $x_i = -\mu/2$. So, plugging-in in this value of x_i in this Lagrangian we can write the Wolfe dual as maximize Lagrangian function; subject to the constraint that the gradient Lagrangian with respect to x is 0.

And, using this value of x_i which is $-\mu/2$ we can write the Wolfe dual as max of $-\mu/4 - \mu^2/4$. So, you will see that the dual problem here is unconstrained problem in terms of only 1 variable. the primal problem had n variables and

1 equality constraint the dual problem has a only 1 variable and it is a unconstraint problem. This problem is much easier to solve and as we saw last time μ^* is -2 by n and that gives x^* to be 1 by n which is same as what we saw earlier. So, many a times the dual problem is easier to solve than the primal problem. Also note that if we have a very large value of n then solving this primal will be difficult. Instead it will be easy to solve this dual problem. Now, let us look at another program.

(Refer Slide Time 59:40)

Example: Consider the *Linear Program (LP)*,

$$\begin{aligned} \min \quad & c^T x \\ \text{s.t.} \quad & Ax = b \\ & x \geq 0 \end{aligned}$$

where $A \in \mathbb{R}^{m \times n}$ and $\text{rank}(A) = m < n$.

- Convex programming problem
- Slater's condition holds
- $\mathcal{L}(x, \lambda, \mu) = c^T x + \mu^T (b - Ax) - \lambda^T x$
- $\nabla_x \mathcal{L}(x, \lambda, \mu) = 0 \Rightarrow c - A^T \mu - \lambda = 0$

Wolfe dual problem (Dual-LP):

$$\left. \begin{aligned} \max \quad & \mathcal{L}(x, \lambda, \mu) \\ \text{s.t.} \quad & \nabla_x \mathcal{L}(x, \lambda, \mu) = 0 \\ & \lambda \geq 0 \end{aligned} \right\} \equiv \begin{aligned} \max \quad & b^T \mu \\ \text{s.t.} \quad & A^T \mu \leq c \end{aligned}$$

NPTEL Shirish Shrivastava Numerical Optimization

This program is popularly known as linear program. We will discuss about linear problem sometime later but the problem formulation is like this. We want to minimize a function c transpose x ; subject to the Subject to the constraint x equal to b x greater than or equal to 0 ; where A is m by n matrix, and the rank of the matrix A is m which is less than n . The reason why this is called the linear program is that the objective function is linear and the constraints are linear in terms of the variables. Now, we can clearly see that this constraint set is a convex set and the objective function is also a convex function. So, minimizing a convex function convex constraint set is a convex programming problem.

Also, let us assume that the feasible set that we have is a nonempty set and moreover it is also a non singleton set. So, which means that there exist a point which lies in the interior of the constraint set. So, that implies that the Slater is condition holds. Now, with these 2 properties that the linear program is convex linear problem and assuming that the Slater

is condition holds; we can write the Wolfe dual of this problem. So, to write the Wolfe dual we need a Lagrangian. Now, there are some equality constraints and some inequality constraints. So, there will be a Lagrangian multipliers corresponding to these equality constraints which we are going to call them as μ . And, the Lagrangian multipliers corresponding to the inequality constraints; we are going to call them as λ .

So, the Lagrangian is the objective function plus μ transpose b minus Ax minus λ transpose x . And, the gradient of the Lagrangian with respect to x equal to 0 implies that c minus A transpose μ minus λ equal to 0. We need this condition when we write the Wolfe dual. So, that is why we have calculated beforehand, and then we are in a position to write the Wolfe dual. So, Wolfe dual of this is the formulation which is given here is maximize the Lagrangian subject to the constraint; that the gradient of the Lagrangian with respect to x is 0. And, then the Lagrangian multipliers corresponding to the inequality constraints are non negative.

So, if you consider this Lagrangian and consider the fact that the we need to satisfy this constraint that the gradient of the Lagrangian should vanish. So, c minus a transpose will be λ minus equal to 0. So, let us substitute this in the Lagrangian expression and what we will get is only the term involving μ and b . Because the other terms c transpose x minus μ transpose Ax minus λ transpose Ax will get cancelled because of this condition. So, the Wolfe dual of this problem is maximize b transpose μ subject to the constraint; that A transpose μ less than or equal to c .

So, this condition is arrived at by using this expression. So, we have this constraint that the gradient of the Lagrangian should vanish. So, which means that a minus a transpose μ minus λ equal to 0. Therefore, c minus μ equal to λ and λ is are nonnegative. So, c minus a transpose μ is greater than or equal to 0 or in other words a transpose μ is less than or equal to c . Now, this Wolfe dual you just only the variable μ , the variable λ does not appear anywhere in this dual.

So, you can see that is in the original problem the matrix of A size is m by n . So, the number of μ is that we here will be equal to m . So, this becomes a m dimensional optimization problem. And, moreover the variables μ is are unconstrained; unlike the original primal variables are which a non negativity constraint in them. Also, you will

see that there are no terms in the dual which involve lambda. So, the number of constraints in this problem, the number equality constraints in this original linear program is equal to the number of variables in the Wolfe dual. Therefore, if m is the very much less than n; then it may be a good idea to solve this problem instead of the original linear program. Now, let us take this dual problem and see what happens if we write the dual of this problem? So, let us take.

(Refer Slide Time: 1:05:40)

The image shows a whiteboard with handwritten mathematical derivations. At the top, a maximization problem is written: $\max b^T \mu$ subject to $A^T \mu \leq c$. This is equated to a minimization problem: $\min -b^T \mu$ subject to $A^T \mu \leq c$. Below this, the Lagrangian function is defined as $L_D = -b^T \mu + \alpha^T (A^T \mu - c)$. The dual problem is then written as $\max L_D$ subject to $\nabla_{\mu} L_D = 0$ and $\alpha > 0$. This is further simplified to $\max -b^T \mu + \alpha^T (A^T \mu - c)$ subject to $-b + A\alpha = 0$ and $\alpha > 0$.

So, we have maximize b transpose μ subject to the constraint A transpose μ less than or equal to c . So, we want to write down the dual of this problem. So, this problem let us first bring it to the minimization form. And this problem is nothing but minimize minus b transpose μ subject to A transpose μ less than or equal to c . So, let us 1st write down the dual of the problem which is given in this box and then use the negative sign. So, let us look at only this problem 1st. Now, to write the dual we need to write the Lagrangian. So, let us first write down the Lagrangian of this we will call it as L_D because d stands for the dual.

So, Lagrangian of this dual problem that we are going to write and that is nothing but minus b transpose μ plus α transpose A transpose μ minus c this is the Lagrangian. And note that this is also a linear programming problem. So, it is also a convex programming problem and let us assume that the Slater is constraint qualification holds. So, we can write the Wolfe dual of this. So, Wolfe dual of this problem will be maximize

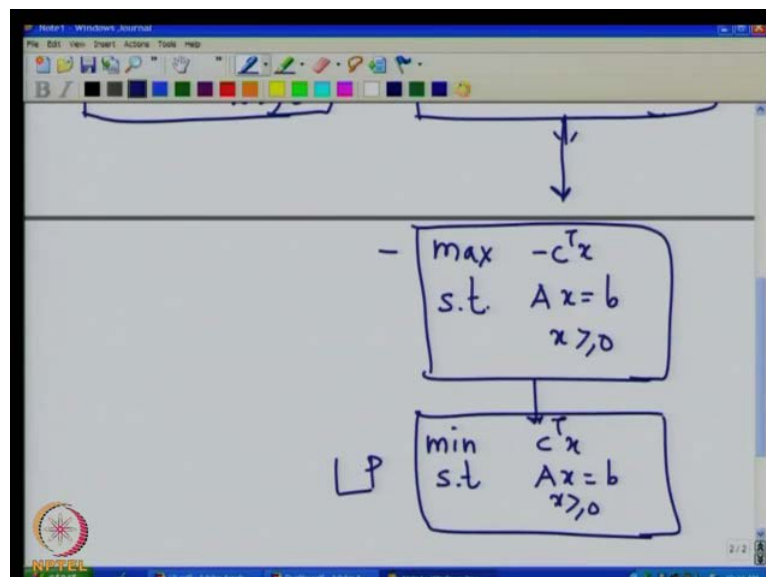

LD subject to the constraint that gradient of LD with respect to the primal variable which is μ is equal to 0; and the Lagrangian multipliers corresponding to the inequality constraints are nonnegative.

So, here x are the Lagrangian multipliers. So, x greater than or equal to 0 or which is same as maximize minus $b^T \mu$ plus $x^T A^T \mu$ minus $c^T x$ constraint qualification holds. So, we can write the Wolfe dual of this. So, Wolfe dual of this problem will be maximize LD subject to the constraint that gradient of LD with respect to the primal variable which is μ is equal to 0; and the Lagrangian multipliers corresponding to the inequality constraints are nonnegative.

So, here x are the Lagrangian multipliers. So, x greater than or equal to 0 or which is same as maximize minus $b^T \mu$ plus $x^T A^T \mu$ minus $c^T x$ subject. So, let us calculate the gradient of LD with respect to μ . So, which will be minus b plus Ax equal to 0 and x greater than or equal to 0.

So, let us take this condition what we have here minus b plus Ax equal to 0 which is same as Ax plus b . And if we substitute this condition in the objective function these 2 terms gets cancelled.

(Refer Slide Time: 1:09:54)

And, what we are left with is minus $c^T x$ where maximize minus $c^T x$ subject to Ax equal to b x greater than or equal to 0. So, the this problem which is the

dual of the problem which is given in the box is. So, the dual of this problem we can write this as maximize minus $c^T x$ subject to Ax equal to b x greater than or equal to 0.

And, remember that there was a minus sign which we had not considered. So, we will consider that now so, we have the minus sign. So, here also we will use the minus sign and we will carry that minus sign here. And, now even we consider the equivalent problem from the negative of max of this quantity is same as minimize $c^T x$ subject to Ax equal to b x greater than or equal to 0. And, this was nothing but the linear program that we started with. So, if you write down the dual of the linear program which is this. And, the if we rewrite the dual of this dual it is same as the original linear program. So, this is where interesting property associated with linear programs. Now, so for we were able to write the dual problem in terms of the Lagrangian multipliers associated with equality and the inequality constraints; but that may not always be the case.

(Refer Slide Time: 1:11:49)

Example: Consider the *Quadratic Program*,

$$\begin{aligned} \min \quad & \frac{1}{2}x^T Hx + c^T x \\ \text{s.t.} \quad & Ax \geq b \end{aligned}$$

where $H \in \mathbb{R}^{n \times n}$ is a symmetric positive semi-definite matrix and $A \in \mathbb{R}^{m \times n}$, $\text{rank}(A) = m$.

$$\mathcal{L}(x, \lambda) = \frac{1}{2}x^T Hx + c^T x + \lambda^T (b - Ax)$$

$$\nabla_x \mathcal{L}(x, \lambda) = 0 \Rightarrow Hx + c - A^T \lambda = 0$$

Therefore, the **Wolfe dual problem** is,

$$\begin{aligned} \max \quad & \frac{1}{2}x^T Hx + c^T x + \lambda^T (b - Ax) \\ \text{s.t.} \quad & Hx - A^T \lambda = -c \\ & \lambda \geq 0. \end{aligned}$$

The dual problem cannot be given explicitly in terms of dual variables.

Shrikant Shrivastava Numerical Optimization

Let us consider a simple example. Let us consider a quadratic program to minimize $x^T Hx + c^T x$ subject to the constraint that Ax equal to b . Now, the H matrix is a n by n positive symmetric semi definite matrix and A is n by m matrix and the rank of A is m . Now, we assume that the Slater is constraint qualification holds; this is a convex programming problem. So, we can write the Lagrangian as the objective function

plus $\lambda^T (b - Ax)$. Now, the gradient of the Lagrangian with respect to x equal to 0 implies that $Hx + c - A^T \lambda = 0$.

And, therefore Wolfe dual of this original quadratic program is like this where we maximize half of $x^T H x + c^T x + \lambda^T (b - Ax)$; subject to the constraint that $Hx + c - A^T \lambda = 0$ and λ is nonnegative. Now, you will see here that the number of variables in this dual problem is more than the number of variables that we have in the original primal problem. Here, the number of variables where n associated with the variable x or here the number of variables will be $n + m$ associated with x and λ . So, in this case we really do not gain anything by writing the Wolfe dual. Because we have simply increase the number of variables and the problem also does not get simplified. Because we still have the quadratic programming problem with very linear constraints; same as what we had in the primal problem where the objective function was quadratic and the constraints were linear.

So, we do not gain we do not really gain anything in this case. So, this is an example where the dual problem cannot be given explicitly in terms of dual variables. Here, the variables associated with the dual problem are both x as well as λ this has to be kept in mind. But things can be simpler if we assume that the matrix H is positive definite matrix instead of the semi definite matrix. Because if H is positive definite then H is invertible. So, we can write x in terms of λ is by using the fact that H is invertible. And, then I can write the dual problem in terms of only the dual variables which are λ .

(Refer Slide Time: 1:15:03)

Example: Consider the *Quadratic Program*,

$$\begin{aligned} \min \quad & \frac{1}{2} \mathbf{x}^T \mathbf{H} \mathbf{x} + \mathbf{c}^T \mathbf{x} \\ \text{s.t.} \quad & \mathbf{A} \mathbf{x} \geq \mathbf{b} \end{aligned}$$

where $\mathbf{H} \in \mathbb{R}^{n \times n}$ is a symmetric **positive definite** matrix.

$$\mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}) = \frac{1}{2} \mathbf{x}^T \mathbf{H} \mathbf{x} + \mathbf{c}^T \mathbf{x} + \boldsymbol{\lambda}^T (\mathbf{b} - \mathbf{A} \mathbf{x})$$

$$\nabla_{\mathbf{x}} \mathcal{L}(\mathbf{x}, \boldsymbol{\lambda}) = 0 \Rightarrow \mathbf{H} \mathbf{x} + \mathbf{c} - \mathbf{A}^T \boldsymbol{\lambda} = \mathbf{0}$$

Therefore, the **Wolfe dual problem** is,

$$\begin{aligned} \max \quad & \frac{1}{2} \mathbf{x}^T \mathbf{H} \mathbf{x} + \mathbf{c}^T \mathbf{x} + \boldsymbol{\lambda}^T (\mathbf{b} - \mathbf{A} \mathbf{x}) \\ \text{s.t.} \quad & \mathbf{H} \mathbf{x} + \mathbf{c} - \mathbf{A}^T \boldsymbol{\lambda} = \mathbf{0} \\ & \boldsymbol{\lambda} \geq \mathbf{0}. \end{aligned}$$

Using $\mathbf{x} = \mathbf{H}^{-1}(\mathbf{A}^T \boldsymbol{\lambda} - \mathbf{c})$, the dual problem is,

$$\max_{\boldsymbol{\lambda} \geq \mathbf{0}} \quad -\frac{1}{2} \boldsymbol{\lambda}^T \mathbf{A} \mathbf{H}^{-1} \mathbf{A}^T \boldsymbol{\lambda} + (\mathbf{A} \mathbf{H}^{-1} \mathbf{c} + \mathbf{b})^T \boldsymbol{\lambda}$$

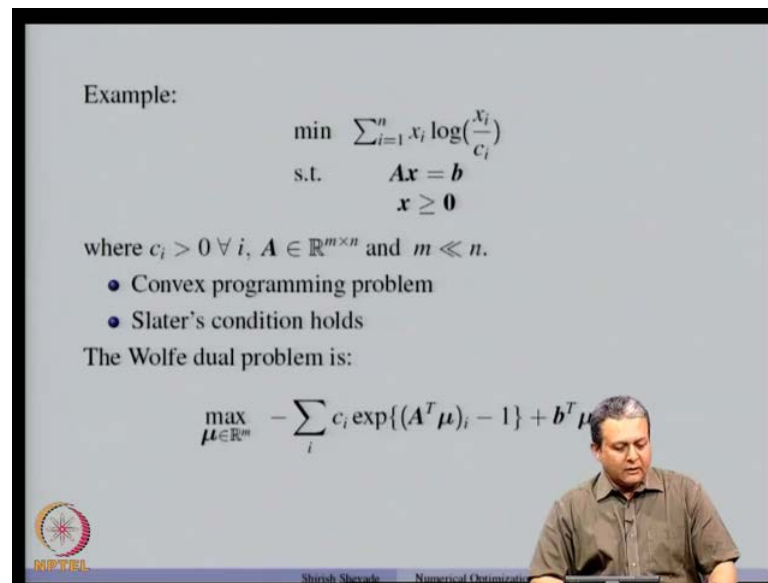

Shreshth Shrivastava Numerical Optimization

So, let us see how to do that? So, as in the previous case we write the Lagrangian and then said that the gradient of the Lagrangian with respect to \mathbf{x} to 0; which gives us this equation $\mathbf{H} \mathbf{x} + \mathbf{c} - \mathbf{A}^T \boldsymbol{\lambda} = \mathbf{0}$.

And, then we can write the Wolfe dual by using \mathbf{x} equal to $\mathbf{H}^{-1}(\mathbf{A}^T \boldsymbol{\lambda} - \mathbf{c})$. So, we use this equation and write \mathbf{x} in terms of $\boldsymbol{\lambda}$. And, then the dual problem becomes maximize $\boldsymbol{\lambda}$ with respect to $\boldsymbol{\lambda}$; the quantity minus half $\boldsymbol{\lambda}^T \mathbf{A} \mathbf{H}^{-1} \mathbf{A}^T \boldsymbol{\lambda}$ plus $(\mathbf{A} \mathbf{H}^{-1} \mathbf{c} + \mathbf{b})^T \boldsymbol{\lambda}$. So, you will see that by using this transformation we were able to eliminate \mathbf{x} from the dual problem. And, this dual problem is now in terms of only the dual variables which are $\boldsymbol{\lambda}$. And, typically these will be less in number compared to the number of variables in the original primal problem.

Further this problem has the simple constraint of the type $\boldsymbol{\lambda} \geq \mathbf{0}$ compared to the constraint of the type $\mathbf{A} \mathbf{x} \geq \mathbf{b}$ in the original primal problem. So, this problem will be easier to solve compared to the original primal problem. So, this an example where we 1st saw that the dual problem cannot be written explicitly in terms of dual variables. But then if the $(())$ matrix in the original quadratic program is symmetric positive definite matrix. Then, one can write the primal variables in terms of the dual variable by using the fact that \mathbf{H} is invertible. And, then 1 can write the dual problem only in terms of dual variables.

(Refer Slide Time: 1:17:06)

Example:

$$\begin{aligned} \min \quad & \sum_{i=1}^n x_i \log\left(\frac{x_i}{c_i}\right) \\ \text{s.t.} \quad & \mathbf{Ax} = \mathbf{b} \\ & \mathbf{x} \geq \mathbf{0} \end{aligned}$$

where $c_i > 0 \forall i$, $\mathbf{A} \in \mathbb{R}^{m \times n}$ and $m \ll n$.

- Convex programming problem
- Slater's condition holds

The Wolfe dual problem is:

$$\max_{\boldsymbol{\mu} \in \mathbb{R}^m} - \sum_i c_i \exp\{(A^T \boldsymbol{\mu})_i - 1\} + \mathbf{b}^T \boldsymbol{\mu}$$

NPTEL

Let us see 1 more example where we minimize $\sum x_i \log(x_i/c_i)$; where c_i is a positive constant and the constraints are $\mathbf{Ax} = \mathbf{b}$, $\mathbf{x} \geq \mathbf{0}$; and \mathbf{A} is n by m matrix where m is much less than n . Now, you can verify that the objective function is a convex function of \mathbf{x} . Now, we have already seen that the constraint of this type $\mathbf{x} = \mathbf{b}$, $\mathbf{x} \geq \mathbf{0}$ which we saw in the linear program case these constraints form a convex set. So, this is an example of a convex programming problem. And assuming that the Slater's condition holds; one can write the Wolfe dual of this problem. So, it turns out that the Wolfe dual of this problem is very easy to write.

And, you will see that the Wolfe dual is a maximization problem with respect to $\boldsymbol{\mu}$ and the $\boldsymbol{\mu}$ is unrestricted in sign. So, the dual of this problem is an unconstrained optimization problem which is easier to solve. So, I will leave it as an exercise to write the dual of this problem and compare that with the 1 which is given here. Now, before we conclude our discussion on duality theory; I would like to make 1 important remark about the dual problem. We have already seen that in many cases the dual problem is easier to solve than the primal problem. But there is 1 important property of dual problems which makes them very attractive. So, let us see that property.

(Refer Slide Time: 1:19:09)

Consider the problem (NLP):

$$\begin{aligned} \min \quad & f(\mathbf{x}) \\ \text{s.t.} \quad & h_j(\mathbf{x}) \leq 0, \quad j = 1, \dots, l \\ & e_i(\mathbf{x}) = 0, \quad i = 1, \dots, m \\ & \mathbf{x} \in X \text{ where } X \text{ is a compact set.} \end{aligned}$$

- Dual Function:

$$\theta(\boldsymbol{\lambda}, \boldsymbol{\mu}) = \min_{\mathbf{x} \in X} f(\mathbf{x}) + \sum_{j=1}^l \lambda_j h_j(\mathbf{x}) + \sum_{i=1}^m \mu_i e_i(\mathbf{x})$$
- Dual function is a pointwise minimum of a family of affine functions of $(\boldsymbol{\lambda}, \boldsymbol{\mu})$.
 $\therefore \theta(\boldsymbol{\lambda}, \boldsymbol{\mu})$ is a *concave* function.
- $$\begin{aligned} \max \quad & \theta(\boldsymbol{\lambda}, \boldsymbol{\mu}) \\ \text{s.t.} \quad & \boldsymbol{\lambda} \geq \mathbf{0} \end{aligned}$$

Therefore, the dual problem is a convex programming problem
even if the primal problem is not!

MPTEL Shreshth Shrivastava Numerical Optimization

So, let us consider a general non-linear programming problem of the type minimize $f(\mathbf{x})$ subject to the constraint that $h_j(\mathbf{x}) \leq 0$ and $e_i(\mathbf{x}) = 0$; where \mathbf{x} is a compact set and \mathbf{x} belongs to the compact set. So, \mathbf{x} lies in the intersection of the set set of constraints which are represented as $h_j(\mathbf{x}) \leq 0$, $e_i(\mathbf{x}) = 0$ and then the compact set X . Now, let us look at the dual function which was defined as $\theta(\boldsymbol{\lambda}, \boldsymbol{\mu})$ to be minimize $\min_{\mathbf{x} \in X} f(\mathbf{x}) + \sum_{j=1}^l \lambda_j h_j(\mathbf{x}) + \sum_{i=1}^m \mu_i e_i(\mathbf{x})$. Note that as i mentioned earlier truly speaking this is should be Infimum of $\min_{\mathbf{x} \in X} f(\mathbf{x}) + \sum_{j=1}^l \lambda_j h_j(\mathbf{x}) + \sum_{i=1}^m \mu_i e_i(\mathbf{x})$. But we assume that the minimum exists so, if the minimum does not exist I has to write the Infimum.

Now, the important point that the we should note that this dual function $\theta(\boldsymbol{\lambda}, \boldsymbol{\mu})$ is a point wise minimum of family of affine functions of $\boldsymbol{\lambda}$ and $\boldsymbol{\mu}$. So, the dual function is a function of $\boldsymbol{\lambda}$ and $\boldsymbol{\mu}$ and it is obtained by a point wise minimum of different affine functions. And, we already know that such a function is a concave function. So, the point wise minimum of family of affine functions is a concave function. Therefore, the dual function is a concave function. And, the dual problem which is maximize $\theta(\boldsymbol{\lambda}, \boldsymbol{\mu})$ subject to $\boldsymbol{\lambda} \geq \mathbf{0}$.

So, we maximize the concave function subject to this convex set $\boldsymbol{\lambda} \geq \mathbf{0}$. And, maximization of a concave function can be written as minimization of a convex corresponding convex function and which is a convex programming problem. So,

irrespective of what the primal problem is or what is what the nature of the problem is the dual problem is always a convex programming problem. And, therefore it becomes very attractive to solve this dual problem. Because there is no question of local minima as far as dual problems are concerned. So, therefore many applications typically are based on the dual problems because which are convex programming problems. And, then the solution of the primal problem can be obtained by after obtaining solution of the dual problem. So, with this we conclude our discussion on duality theory.

Thank you.
