**Differential Relations**

Hello good morning. Welcome back. So, in the last few classes we discussed about the Forward and Inverse Kinematics of manipulator. So, this forward and inverse basically is a position relationship so we were trying to see how we can relate the joint positions to the tool position or if we know the tool position how can we get the joint position or if we know the joint position how can we get the tool position.

So that was the forward and inverse kinematic relationships. But in most of the robot applications we are not only interested in position, but we are interested in the velocity relationship also.

(Refer Slide Time: 00:57)

## Differential Relations

Dr. T. Asokan  
IIT Madras  
[asok@iitm.ac.in](mailto:asok@iitm.ac.in)

For example, if you have a robot and the tool tip is given like this. So we want this to move to this position and this position we just want this to have a particular velocity also. So we want this to move from here to here with a particular velocity in the Cartesian space or we want to say the tool configuration we want to have a velocity. So, we want this to be move from this position A to B with a particular velocity.

As a constant velocity or velocity profile defined by the user we want this to move and if that is the case we need to move the joints also so this joint also need to have some velocity to get the Cartesian velocity. So, if we have an  $\dot{X}$  we want to  $\dot{X}$  we need to know what is the  $\dot{\theta}$  corresponding to that and then how can this be related that is the velocity relationship or differential relationship.

So, how this  $\dot{\theta}$  the joint velocity and the Cartesian velocity  $\dot{X}$  are related is known as the differential relationship or differential kinematics in manipulator kinetics or in the manipulator analysis we call this as the differential kinematics. So, we will try to see how we can develop this relationship once we have the position relationship how can we convert or derive the differential relationship for manipulator so that is going to be the discussion we are going to have.

(Refer Slide Time: 02:37)

The slide is titled "Differential Motion and Statics". It contains a list of topics:

- Tool configuration and Joint Space velocity
- Jacobian
  - Tool configuration Jacobian
  - Manipulator Jacobian
- Singularity
  - Boundary Singularity
  - Interior Singularity
- Generalised inverse
- Pseudo Inverse
- Statics
- Examples

Handwritten notes on the slide include:

- A red circle containing the equations:
 
$$\dot{X} = f(\dot{\theta})$$

$$\dot{\theta} = f^{-1}(\dot{X})$$
- A red asterisk next to the title.
- A red circle around the equations.

The slide also features the NPTEL logo, a small image of a person, and the text "Introduction to Robotics" and "19" at the bottom.

So, we will talk about the tool configuration and joint space velocity. So, joint space velocity is basically the  $\dot{\theta}$  and then the  $\dot{\theta}$  and tool configuration velocity is the  $\dot{X}$ . So, you have  $\dot{\theta}$  and  $\dot{X}$ . What is the relationship between  $\dot{\theta}$  and  $\dot{X}$  is the one which we will see that is the tool configuration velocity and joint space velocity. When I say  $\dot{X}$  it shows that it is  $xyz$  as well as the angular velocities linear and angular velocity in the Cartesian space.

And when we have when we develop this relationship we will see that this two are related to a matrix and then that is basically we called as Jacobian of the manipulator or Jacobian matrix. So, we will talk about the tool configuration Jacobian as a velocity relationship and

then we we can mentioned this as the manipulator Jacobian which is the generalized form of this Jacobian which can be used for other applications also.

Not only velocity relationship we can use it for the force relationship also. Now when we go through this and when we know that you need to get  $\dot{x}$  from  $\dot{\theta}$  we can actually get the  $\dot{x}$  from  $\dot{\theta}$  if we know  $\dot{\theta}$  we will be able to get  $\dot{x}$  dots because  $\dot{\theta}$  is what we can control so we will be able to get  $\dot{x}$  dots. The other way is also possible that  $\dot{\theta}$  can be represented as a function of  $\dot{x}$  dots.

And we call this as a inverse relationship and when we have this kind of relationship and we will see that in some situation or within the workspace of the manipulator there may be many points where we cannot move the manipulator because of some constraints and that we call it as the singularity in the workspace. So, we will talk about the singularity and how they are actually related to the tool configuration and space joints space velocity and also we will try to understand.

And then when we talk about singularity, there are two types basically the boundary singularity and the interior singularity which we will discuss and we will talk about something called generalized inverse because when we try to find out this inverse relationship for the velocity we will find some difficulty in getting the inverse of a matrix then we will use something called generalized inverse to solve this problem.

And finally we will that is pseudo inverse is one form of the generalized inverse and finally we will talk about the statics also where we will be using the relationship that we developed in the differential kinematics to solve for the static analysis of manipulators. So, this is going to be the discussion that we are going to have of course we will solve the examples as the discuss in all this topics.

Differential relationship

• Robot path planning problem is formulated in tool-configuration space

• Robot motion is controlled at the joint space

$x = w(q)$ ,  $x$  = tool configuration vector,  
 $w$  = tool-configuration function and  $q$  = joint variables

Differential relationship

$\dot{x} = J(q)\dot{q}$ ,  $J(q)$  is a  $6 \times n$  matrix and is called the Jacobian matrix or Jacobian

$J_{ij}(q) = \frac{\partial v_i(q)}{\partial q_j}$ ,  $1 \leq k \leq 6$ ,  $1 \leq j \leq n$

$X = FK(\theta)$   
 $\theta = IK(X)$

$\dot{X} = J(q)\dot{q}$

Introduction to Robotics 20

So, I already mentioned about the differential relationship so we have theta that is the joint parameters or the joint positions and then you have this position of the tool tip which has got the position vector and the orientation also. So you have the position and orientation of the tool in the Cartesian space that is known as the tip location Cartesian space and then you have the tip location in joint space.

So, the tip location in joint space is represented by the corresponding joint angles which give you the tip location and as we know that they are related through the forward kinematics so F is forward kinematics of theta and theta is the inverse kinematics of X. So if we know X, we can apply inverse kinematics and get the theta and if you know theta, you will be able to get the X using the forward kinematics so that is the relationship we have.

Now what we are interested in this getting the  $\dot{X}$  and theta dots. So, the the reason why we need to do is to the robot path planning and problem is formulated in tool configuration space because you are interested in the velocity of the tool and most of our problem will be formulated as velocity of tool or end effector and the robot motion is controlled at the joint space.

So always the motion is controlled at the joint space we cannot control the tip directly though we want the tip to have a particular velocity we cannot comment that the velocity directly we need to comment the joint velocity. So, we can control the theta dots and then we need to get the  $\dot{x}$  dots. So, what kind of relationship exist between these two is important for us to comment theta dots.

So, how do we actually comment theta dots to get a  $\dot{x}$  dot or for a given for a desired  $\dot{X}$  dot so I have a desired  $\dot{x}$  dots I want to know what theta dot will give actually give me this  $\dot{X}$  dots. So that is the relationship we are interested so that I can move theta or move the joint with a particular velocity so that I will get to decide  $\dot{X}$  dot at the end effect. So this can actually be obtained if you represent  $x$  as  $wq$  where  $w$  is the relationship between  $q$ ,  $q$  is the joint variable.

$$x = w(q); \quad x = \text{tool configuration vector,}$$

$$w = \text{tool-configuration function and } q = \text{joint variables}$$

So we will refer theta in case theta, theta is angle, but we refer  $q$  as a joint variable where it is theta or  $d$  for prismatic or rotary joint we can use  $q$  as the joint variable and then we can say that  $x$  is  $wq$  that is the function of  $q$  instead of FK with that axis  $wq$  where  $w$  is the tool configuration function and  $q$  is a joint variable. Now we can actually  $\dot{x}$  dot if you want to write we will be able to write  $\dot{x}$  dots as a function of  $\dot{q}$  dot.

And the relation between this  $\dot{x}$  dot and  $\dot{q}$  dot this is theta dot, theta dot and  $\dot{x}$  dots so this can be written as  $\dot{x}$  dot is equal to  $J \dot{q}$  dot. So, we will be able to write this  $\dot{x}$  dot as the function can be written as  $J \dot{q}$  dots where  $J$  is known as the Jacobian and it can be obtained by taking the partial derivative of  $w$  with respect to  $q$ . So if we have  $X$  is  $wq$  so we have  $x$  is equal to  $wq$  so we can write it as  $\dot{x}$  dot is equal to partial derivative of  $w \dot{q}$  dots.

Differenti al relationship

$\dot{x} = J(q)\dot{q}$ ;  $J(q)$  is a  $6 \times n$  matrix and is called the Jacobian matrix

or Jacobian

$$J_{kj}(q) = \frac{\partial w_k(q)}{\partial q_j} \quad 1 \leq k \leq 6, \quad 1 \leq j \leq n$$

So, that is the relationship that you can get. So when X is equal to wq, we will be able to write x dot is equal to partial derivative of w with respect to q, q dots so that is the relationship that we can see. So, we will be able to write x dot is equal to J q q dots where J is the matrix which relates the joint velocity and Cartesian velocity and this matrix is known as the Jacobian matrix of the manipulator or we call the tool configuration Jacobian.

$$\begin{array}{c}
 \begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \\ \omega_x \\ \omega_y \\ \omega_z \end{bmatrix} \\
 6 \times 1
 \end{array}
 =
 \begin{array}{c}
 \begin{bmatrix}
 \frac{\partial w_1}{\partial q_1} & \frac{\partial w_1}{\partial q_2} & \frac{\partial w_1}{\partial q_3} & \dots & \frac{\partial w_1}{\partial q_n} \\
 \frac{\partial w_2}{\partial q_1} & \frac{\partial w_2}{\partial q_2} & \frac{\partial w_2}{\partial q_3} & \dots & \frac{\partial w_2}{\partial q_n} \\
 \frac{\partial w_3}{\partial q_1} & \frac{\partial w_3}{\partial q_2} & \frac{\partial w_3}{\partial q_3} & \dots & \frac{\partial w_3}{\partial q_n} \\
 \frac{\partial w_4}{\partial q_1} & \frac{\partial w_4}{\partial q_2} & \frac{\partial w_4}{\partial q_3} & \dots & \frac{\partial w_4}{\partial q_n} \\
 \frac{\partial w_5}{\partial q_1} & \frac{\partial w_5}{\partial q_2} & \frac{\partial w_5}{\partial q_3} & \dots & \frac{\partial w_5}{\partial q_n} \\
 \frac{\partial w_6}{\partial q_1} & \frac{\partial w_6}{\partial q_2} & \frac{\partial w_6}{\partial q_3} & \dots & \frac{\partial w_6}{\partial q_n}
 \end{bmatrix} \\
 6 \times n
 \end{array}
 \begin{array}{c}
 \begin{bmatrix} \dot{q}_1 \\ \dot{q}_2 \\ \dot{q}_3 \\ \vdots \\ \dot{q}_n \end{bmatrix} \\
 n \times 1
 \end{array}$$

Because it relates the tool configuration velocity to the joint velocity so we call it as the tool configuration Jacobian and the elements of J so now J will be 6 by n matrix because n is the number of degrees of freedom and we have 3 linear velocity and 3 angular velocity so this will be 6 and it will be a 6 by n matrix and this element of J  $J_{kj}$  is given as partial derivative of  $w_k$  with respect to  $q_j$  so that is basically the elements of Jacobian.

So, once we have the forward relationship  $x = wq$  so that is basically the forward kinematic relationship. We can take the partial derivative of that relationship with respect to the joint variables and that will give you the Jacobian matrix and then  $\dot{x}$  will be Jacobian multiplied by  $\dot{q}$  so that is the relationship velocity relationship that you can derive from the forward kinematics.

$$\dot{x} = [J(\theta)]\dot{\theta}$$

$$\dot{\theta} = [J(\theta)]^{-1}\dot{x}$$

So, J is the Jacobian which relates the tool configuration velocity to the joint velocity. So, this is the relationship  $\dot{x}$  is J  $\dot{q}$  dots so if you know  $\dot{q}$  dots, you can actually get the  $\dot{x}$  dots by simply multiplying  $\dot{q}$  dot with J so that is Jacobian. So, k is 1 to 6 and then j is 1 to n, n is the number of degrees of freedom.

(Refer Slide Time: 11:31)

The slide shows the derivation of the Jacobian matrix for a rotary manipulator. It starts with the equation  $X = wq$ , where  $X$  is a  $6 \times 1$  vector of linear and angular velocities, and  $q$  is an  $n \times 1$  vector of joint positions. The Jacobian matrix  $J$  is defined as the matrix of partial derivatives of the elements of  $X$  with respect to the elements of  $q$ . The matrix is shown as:

$$\begin{bmatrix} \frac{\partial w_1}{\partial q_1} & \frac{\partial w_1}{\partial q_2} & \frac{\partial w_1}{\partial q_3} & \dots & \frac{\partial w_1}{\partial q_n} \\ \frac{\partial w_2}{\partial q_1} & \frac{\partial w_2}{\partial q_2} & \frac{\partial w_2}{\partial q_3} & \dots & \frac{\partial w_2}{\partial q_n} \\ \frac{\partial w_3}{\partial q_1} & \frac{\partial w_3}{\partial q_2} & \frac{\partial w_3}{\partial q_3} & \dots & \frac{\partial w_3}{\partial q_n} \\ \frac{\partial w_4}{\partial q_1} & \frac{\partial w_4}{\partial q_2} & \frac{\partial w_4}{\partial q_3} & \dots & \frac{\partial w_4}{\partial q_n} \\ \frac{\partial w_5}{\partial q_1} & \frac{\partial w_5}{\partial q_2} & \frac{\partial w_5}{\partial q_3} & \dots & \frac{\partial w_5}{\partial q_n} \\ \frac{\partial w_6}{\partial q_1} & \frac{\partial w_6}{\partial q_2} & \frac{\partial w_6}{\partial q_3} & \dots & \frac{\partial w_6}{\partial q_n} \end{bmatrix} \begin{bmatrix} q_1 \\ q_2 \\ q_3 \\ \vdots \\ q_n \end{bmatrix}$$

For a rotary manipulator, the Jacobian matrix is used to relate the joint velocities to the tool configuration velocities:

$$\dot{x} = [J(\theta)]\dot{\theta}$$

$$\dot{\theta} = [J(\theta)]^{-1}\dot{x}$$

The slide also includes the NPTEL logo and the text "Introduction to Robotics" and "21".

So, this can be written in the matrix form as like this, so if your  $X$  is  $wq$  we will be able to write down the J elements as like this. So, you have this  $\dot{x}$  as  $\dot{x}$  dot  $\dot{y}$  dot and  $\dot{z}$  dots these are the three linear velocities in x direction, y direction and z direction in Cartesian space and then you have this  $\omega_x$ ,  $\omega_y$ ,  $\omega_z$  which is the angular velocity with respect to x, y and z axis.

So, these are the 3 linear and 3 angular velocities and then you get this element by taking the partial derivative of  $w_1$  with respect to  $q_1$ ,  $q_2$  to  $q_n$ . So,  $w_1$  is the relationship for  $x$   $P_x$  is function of so we write only the position of  $x$  we know it is a function of  $q$  so we consider this  $w_1$  we write it as  $w_1(q)$  then you take the partial derivative of  $w_1$  with respect to  $q_1$ ,  $q_2$ ,  $q_3$ ,  $q_n$  you will get the first row of the Jacobian that is what the x velocity.

And for y velocity you take the second relationship  $P_y$  relationship so you will be having end relation  $P_y$  is equal to  $w_2(q)$  then you take the partial derivative this  $w_2$  with respect to  $q_1$ ,  $q_2$  etcetera. So, this is the way how you will get the Jacobian elements the elements of the

Jacobian matrix. Now you can see this, this is the 6 by 1 vector 3 linear velocity and 3 angular velocity.

And this is an  $n$  by 1 vector because you have  $n$  joints and therefore there will be  $n$  joint velocities so it is a  $n$  by 1 vector and then this would be a 6 by  $n$  matrix. So, it may not be a square matrix it will be Jacobian will be matrix depending on the dimension of  $n$ , depending on the  $n$ , the dimension of matrix will be 6 by  $n$ . So, for a 7 degree of freedom it will be 6 by 7, for a 5 degree of freedom it will be 6 by 5, for a 6 degree of freedom it will be a 6 by 6 matrix.

So, this is the Jacobian how we get the Jacobian. So, we will take few examples to see how the Jacobian can be developed for any manipulator. So, first we look only the linear velocity parts and then later on I will explain how the angular velocity can be calculated and angular velocity part can be calculated. So, the for the rotary manipulator it will be  $J \dot{\theta}$ ,  $\dot{\theta}$  and you can actually get the inverse also.

Suppose you have this  $\dot{x}$  Known then we can get the  $\dot{\theta}$ . So, if  $\dot{\theta}$  that is a joint velocities are none we can easily calculate the  $\dot{x}$  using the  $J \dot{\theta}$ ,  $\dot{\theta}$ . Now the other case you know what is Cartesian velocity you want to find out the corresponding  $\dot{\theta}$  for a given  $\dot{x}$  what is the  $\dot{\theta}$  can be obtained by getting the inverse of Jacobian.

We take the  $J^{-1} \dot{x}$ . So, in the workspace suppose you have the workspace this is the work space and you want this to move from here to here A to B in the workspace, we can specify what is the velocity you want this want this tool tip to move from A to B if we can specify these velocity we can find out what is the corresponding joint angles, joint velocities using this relationship  $J^{-1} \dot{x}$ .

So, that is the inverse relationship for the velocity so  $\dot{x}$  is  $J \dot{\theta}$  and  $\dot{\theta}$  is  $J^{-1} \dot{x}$ . Although, it is a direct problem of getting  $\dot{\theta}$  and  $\dot{x}$  that will create lot of issues when we start computing the  $\dot{\theta}$  for a corresponding  $\dot{x}$ . We will be discussing that what are the issues, but one issue is that the  $J^{-1}$  so we have to get an inverse of  $J$ .

And one problem immediate problem is that when it is non square matrix how do we take the inverse? So, 5 degree of freedom robots so for a 5 degree of freedom robot this will be 6 by 5

matrix and how do we get the inverse of 6 by 5 matrix and we know that the inverse need to be calculate the inverse we had to have a square matrix and then only we will be able to get the inverse.

But in this case when it is 6 by 5 what we will do does it mean that for this relationship is applicable only for the 6 degree of freedom robots or other robot also can actually use the same relationship that is one immediate problem and another problem is that this J even if it is a square matrix as you know not all matrices can be inverted again depending on the type of matrix and its properties you may find sometime that it cannot be inverted.

Because of its rank, its rank is not equal or there is some problem with the matrix condition number then you would be able to get the inverse. So, these are the two major problem that we will face when we go for the calculation of theta dot from x dots. So, we will discuss that issue later so first let us see how do we get the J for a manipulator, how do we first calculate the Jacobian for a manipulator we will see then later on we will discuss about the problems associated with the inverting of Jacobian.

(Refer Slide Time: 17:28)

Calculation of Jacobian

- Get the Forward Kinematics relationship,  $\mathbf{X} = \mathbf{w}(\theta)$
- Differentiate  $\mathbf{X}$  wrt  $\theta$

Example: Planar 1R robot

The end effector position is given by

$$P_x = r \cos \theta$$

$$P_y = r \sin \theta$$

End effector velocity is given by

$$\dot{P}_x = \dot{x} = -r \sin \theta \cdot \dot{\theta}$$

$$\dot{P}_y = \dot{y} = r \cos \theta \cdot \dot{\theta}$$

$$\begin{bmatrix} \dot{x} \\ \dot{y} \end{bmatrix} = \begin{bmatrix} -r \sin \theta \\ r \cos \theta \end{bmatrix} \dot{\theta}$$

We will take a very simple example initially to see how to calculate the Jacobian. So, we know that these differentiation with respect to theta so we will take a very simple manipulator of a one degree of freedom so we will take a one degree of freedom single link manipulator planar manipulator to make it very simple. So, we will we know that this is the P, I mean this is the tip and this is theta.

The end effector position is given by

$$P_x = r \cos \theta$$
$$P_y = r \sin \theta$$

So, you have only one degree of freedom. So, we can easily write  $P_x$  and  $P_y$  so  $P_x$  is equal to something and  $P_y$  is equal to something so that is giving  $x$  is equal to something multiplied by  $\theta$  and  $y$  is equal to something multiplied by  $\theta$  so this is we will be able to write  $\dot{x}$  is something multiplied by  $\dot{\theta}$  and these elements are basically you will get that this partial derivative of  $P_x$  with respect to  $\theta$ .

And partial derivative of  $P_y$  with respect to  $\theta$  so that will be the element here, partial derivative of  $x$  and partial derivative of  $y$  with respect to  $\theta$ . So this would be the two elements in this case and yes you know it is only  $\dot{x}$  and of course  $\dot{x}$  means  $\dot{x}$  and  $\dot{y}$  in this case  $\dot{P}_x$   $\dot{P}_y$ . So, this is the way how we can actually get it. Now if I do this, we know that  $P_x$  is equal to  $r \cos \theta$   $P_y$  is equal to  $r \sin \theta$ .

$$\begin{aligned} \dot{P}_x = \dot{x} &= -r \sin \theta \cdot \dot{\theta} \\ \dot{P}_y = \dot{y} &= r \cos \theta \cdot \dot{\theta} \end{aligned} \quad \Rightarrow \quad \begin{bmatrix} \dot{x} \\ \dot{y} \end{bmatrix} = \begin{bmatrix} -r \sin \theta \\ r \cos \theta \end{bmatrix} \begin{bmatrix} \dot{\theta} \end{bmatrix}$$

And then to get the Jacobian we take the partial derivative and find out what is the Jacobian that you are getting. So, take the partial derivative of  $P_x$  with respect to  $\theta$  it will be minus  $r \sin \theta$ ,  $\dot{P}_x$  will be minus  $r \sin \theta \cdot \dot{\theta}$  and  $P_y$  will be  $r \cos \theta \cdot \dot{\theta}$ . Now if we write it as a matrix we will get it as  $\begin{bmatrix} \dot{x} \\ \dot{y} \end{bmatrix}$  when I say  $\dot{x}$   $\dot{y}$   $\dot{P}_x$   $\dot{P}_y$  is minus  $r \sin \theta$   $r \cos \theta$   $\dot{\theta}$ .

So, that is the relationship we get and this is for the Jacobian for the single degree of freedom manipulator, it is minus  $r \sin \theta$   $r \cos \theta$ . So, you are talking only about the linear velocity for the time being we will discuss the angular velocity later. So, this is the  $\dot{x}$  and  $\dot{y}$  for this manipulator. So, this is the principle to be followed whether it is a 6 degree of freedom or 7 degree of freedom we will follow the same principle and then start calculating the Jacobian that is what we do in this case.

(Refer Slide Time: 19:54)

Example: 3R Planar Manipulator

$$Px = l_1 C_1 + l_2 C_{12}$$

$$Py = l_1 S_1 + l_2 S_{12}$$

$$Pz = d_3$$

$$\begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \end{bmatrix} = \begin{bmatrix} \frac{\partial p_x}{\partial \theta_1} & \frac{\partial p_x}{\partial \theta_2} & \frac{\partial p_x}{\partial \theta_3} \\ \frac{\partial p_y}{\partial \theta_1} & \frac{\partial p_y}{\partial \theta_2} & \frac{\partial p_y}{\partial \theta_3} \\ \frac{\partial p_z}{\partial \theta_1} & \frac{\partial p_z}{\partial \theta_2} & \frac{\partial p_z}{\partial \theta_3} \end{bmatrix} \begin{bmatrix} \dot{\theta}_1 \\ \dot{\theta}_2 \\ \dot{\theta}_3 \end{bmatrix}$$

$$J = \begin{bmatrix} -l_1 S_1 - l_2 S_{12} & -l_2 S_{12} & 0 \\ l_1 C_1 + l_2 C_{12} & l_2 C_{12} & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

So, let us take the 3R planar manipulator. Again it is only planar we are talking about we will see how can we get the Jacobian. So, look at these so this is the planar manipulator which we already discussed during the forward and inverse kinematic analysis. So, we know what is Px and Py and Pz also we know. So, we have the relationship for Px, Py, Pz because if this is taken as l1, l2 and theta 1, theta 2 etcetera and this is theta 3 we will be able to get it.

$$Px = l_1 C_1 + l_2 C_{12}$$

$$Py = l_1 S_1 + l_2 S_{12}$$

$$Pz = d_3$$

So, the relationship is obtained from the forward kinematics like this Px is l1 C1 plus l2 C12 and Py is l1 S1 plus S12 and Pz is d3 so, that is the relationship. Now what we want to I mean if you want to get Px dots what we need to do is to take the partial derivative of Px with respect to theta 1 and so if you write it like this we will get it as x dot is Px with respect to theta 1, theta 2 and theta 3 and Pz theta 1, theta 2, theta 3.

$$\begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{z} \end{bmatrix} = \begin{bmatrix} \frac{\partial p_x}{\partial \theta_1} & \frac{\partial p_x}{\partial \theta_2} & \frac{\partial p_x}{\partial \theta_3} \\ \frac{\partial p_y}{\partial \theta_1} & \frac{\partial p_y}{\partial \theta_2} & \frac{\partial p_y}{\partial \theta_3} \\ \frac{\partial p_z}{\partial \theta_1} & \frac{\partial p_z}{\partial \theta_2} & \frac{\partial p_z}{\partial \theta_3} \end{bmatrix} \begin{bmatrix} \dot{\theta}_1 \\ \dot{\theta}_2 \\ \dot{\theta}_3 \end{bmatrix}$$

3 X 1      3 X 3      3 X 1

That is the way how we get x dot, y dot and z dots. So, we can see this is 3 by 1 vector, 3 by 3 matrix and it is a 3 by 1 vector. Now, we take Px with respect to theta 1 it is l1 C1 plus l2 C12 so we will be getting this as minus l1 S1 minus l2 S12 and this would be minus l2 S12 and this is l1 C1 plus l2 C12 l2 C12 and this should be 0 because Px with respect to theta 3 Py with respect to theta 3 and Pz with respect to theta 3 are 0.

So this will be the Jacobian for the linear velocity of the manipulator so this is how you can get the Jacobian for manipulators so whether it is a 3 degree of freedom or 5 degree of freedom use the same principle because get the relationship from your forward kinematics Px relationship or X relationship and then take the partial derivative get the matrix so you will be getting the Jacobian for this manipulator.

(Refer Slide Time: 22:08)

Example: Four Axis SCARA Manipulator (Adept 1)

$$Px = l_1 C_1 + l_2 C_{12}$$

$$Py = l_1 S_1 + l_2 S_{12}$$

$$Pz = d_1 - q_3 - d_4$$

$$J = \begin{bmatrix} \frac{\partial P_x}{\partial \theta_1} & \frac{\partial P_x}{\partial \theta_2} & \frac{\partial P_x}{\partial q_3} & \frac{\partial P_x}{\partial \theta_4} \\ \frac{\partial P_y}{\partial \theta_1} & \frac{\partial P_y}{\partial \theta_2} & \frac{\partial P_y}{\partial q_3} & \frac{\partial P_y}{\partial \theta_4} \\ \frac{\partial P_z}{\partial \theta_1} & \frac{\partial P_z}{\partial \theta_2} & \frac{\partial P_z}{\partial q_3} & \frac{\partial P_z}{\partial \theta_4} \end{bmatrix} = \begin{bmatrix} -l_1 S_1 - l_2 S_{12} & -l_2 S_{12} & 0 & 0 \\ l_1 C_1 + l_2 C_{12} & l_2 C_{12} & 0 & 0 \\ 0 & 0 & -1 & 0 \end{bmatrix}$$

Introduction to Robotics 24

There is another example again 4 axis manipulator which is SCARA manipulator 4 axis. So just to ensure that you are thorough with this process, so I am just showing one more example again you will be getting Px like this if you do a forward kinematics you would be getting Px as l1 C1 plus l2 C1 minus 2 then Py is l1 S1 plus l2 S1 minus 2 and Pz is d1 minus q3 minus d4.

$$T_{base}^{tool} = \begin{bmatrix} C_{123} & -S_{123} & 0 & l_1 C_1 + l_2 C_{12} \\ S_{123} & C_{123} & 0 & l_1 S_1 + l_2 S_{12} \\ 0 & 0 & 1 & d_3 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

So, in this case it is a linear joint so you have one linear joint that is why it is known as q3 it is the variable joint 3 the last one is basically a, the third one is a prismatic joints that is why q3 is a variable and d4 is a constant. Again the same principle you apply the take the partial derivative with respect to theta 1, theta 2 and q3 and theta 4. So, here you have Px with respect to theta 1, theta 2, theta 3, q3 and theta 4 same Py Pz also.

$$J = \begin{bmatrix} -l_1 S_1 - l_2 S_{12} & -l_2 S_{12} & 0 \\ l_1 C_1 + l_2 C_{12} & l_2 C_{12} & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

So, these are the joint velocities theta 1 dot, theta 2 dot, q3 dot and theta 4 dots and if you do this partial derivative we will be getting it as this so Jacobian will be this matrix minus l1 S1 minus l2 S1 minus 2 minus l2 S1 minus 2 like that. So, you will be able to get the linear part of the Jacobian by taking the partial derivative like this. I hope you understood this method.

(Refer Slide Time: 24:02)

### Singularities

The joint space velocity is given as  $\dot{\theta} = [J(\theta)]^{-1} \dot{x}$

One of the potential problems with solving for joint space velocity is the non-existence of inverse. The Jacobian may not be invertible for all the values of  $\theta$ .

At certain points in joint space, Jacobian loses its rank; i.e. there is a reduction in no. of independent rows and columns. The points at which the Jacobian loses rank are called Joint space Singularities.

**NOTE:** The Jacobian Matrix  $J(q)$  is of full rank as long as  $q$  is not a joint space singularity.

Manipulator dexterity,  $dex(q) = \det[J^T J]$   $n \leq 6$

For the general case  $n \leq 6$ , the tool Jacobian matrix is less than full rank if and only if the  $n \times n$  matrix  $J^T J$  is singular.

For redundant manipulators ( $n > 6$ ), determinant of the  $6 \times 6$  matrix,  $J^T J$  must be used.

A manipulator is at joint space singularity if and only if  $dex(q) = 0$ .

Boundary singularity occurs when the tool tip is on the surface of the work envelope.

Introduction to Robotics 25

So, let us briefly talk about the issues with Jacobian when we try to do the inverse. So, as I mentioned you can do the theta dots by taking the Jacobian inverse if you know x dots we will be able to calculate theta dot by taking the inverse of the Jacobian J inverse, but many cases you will be having difficulty in calculating the J inverse because J is a function of theta. So, the Jacobian is a function of theta as you saw in the previous cases.

$$\dot{\theta} = [J(\theta)]^{-1} \dot{x}$$

You can see this is a function of theta as theta value changes, the Jacobian matrix also changes. So, for any different position of that tool tip you have different matrix the elements of matrix changes so your Jacobian matrix also changes so, it is not fixed for a manipulator as the position changes your J also varies and there maybe some position in the workspace that this J become non invertible.

That is when that is moving or when the theta value changes, there may be a situation where the Jacobian may not be invertible for all the values of theta. Assuming that J is a square matrix for the time being in that case also when the matrix the manipulator is moving in the workspace, then you will see that at some for some values of theta, the Jacobian may not be invertible that is because the Jacobian loses its rank.

So, if it s 6 by 6 matrix then the rank of the Jacobian will actually come down to 5 at some point then you would not be able to invert it. So, that kind of situation will be common in manipulator or workspace and that kind of situations are known as the singularity. So, at certain points in joint space Jacobian loses its rank. Therefore, some values of theta the Jacobian loses its rank.

And there is a reduction in number of independent rows and columns in the Jacobian. So, initially it was a 6 by 6 matrix, but then after sometime it actually become matrix is still 6 by 6, but the independent rows or columns reduced reduces because of the position of theta and its loses rank it becomes 5 that situation then such situation are called as joint space singularities and you would not be able to invert the Jacobian at that point.

And when you are not able to invert you would not be able to find the theta dots because you have an x dots and at that particular configuration of the manipulator that particular joint positions you find that J inverse is not existing and therefore you will find it theta dot cannot be calculated. For any values of x dot you would not be able to find theta dot for any theta dots you would not be able to get an x dot.

So, if you look at from the other point you want to move the joint, you want to command the joint at very high velocity, but still you are not able to get the desired x dots this situation is known as the joints space singularities and this is common because the Jacobian since it is a function of theta as the theta takes a particular set of value, then for that particular set of value we will see that this relationship is not possible to be evaluated or any value of theta dot you would not be able to get x dots.

Or to get an  $\dot{x}$  desired  $\dot{x}$ , the  $\dot{\theta}$  should be infinite that is the way how you can look at it. If you want to have an  $\dot{x}$  then you need to have an infinite velocity at the joint to get this  $\dot{x}$  such situations are known as joint space singularities or that position of that manipulator is known as singular point or a singular point in the workspace. It can be multiple points need not be a single point.

It can be multiple points or as it reaches that point you will find that the manipulators the Jacobian loses its rank. So, this situation is the joint space singularity. So, the Jacobian matrix  $J_q$  is of full rank as long as  $q$  is not a joint space singularity. So, the  $J_q$  will be of full rank as long as the  $q$  is not a joint space singularity. When this is singular the joint space at singularity then  $J_q$  loses its rank.

And this can actually measured by something called dexterity measure. So, how close the manipulator is to a singular point can be measured by the term dexterity. So, we would define dexterity as the determinant of  $J^T J$  or  $J J^T$  depending on the value of  $n$  is less than or equal to 6 or more than 6. So, this is used to get the dexterity measure if it is greater than 6 then use  $J J^T$ .

So, either  $J^T J$  or  $J J^T$  you find out the determinant of  $J J^T$  and that is known as that will give you the dexterity of the manipulator and for the general, case the tool Jacobian matrix is less than full rank if then only  $n$  by  $n$  matrix  $J$  is singular and for redundant manipulators determinant of 6 by 6 matrix must be used  $n$  is less than 6 or more than 6 and you have to use  $J^T J$  or  $J J^T$ .

$$\text{dex}(q) = \det[J^T J] \quad n \leq 6$$

Now a manipulator is a joint space singularity if and only if dexterity is 0. So, when the dexterity is 0, that is the determinant is 0, for  $J^T J$  or  $J J^T$ , then we call this as the singularity or that space singularity dexterity will be 0. So, when manipulator is starting from one point which is not a singular point or the dexterity is very high then this value will be having a very high value.

Then as it moves towards the singular point you will be getting it as 0. So, as it moves to the singular point it will start coming down very small values and then finally at the singular point you will be getting a dexterity value as 0. So, this is actually a measure of singular

space I mean this dexterity that is, if you have a manipulator workspace like this, then there may be a singular points somewhere here.

Assume that there is a singular point here that is a point the dexterity will be 0 and in other places you will see that as it moves here the dexterity will start coming down to 0. So, it may be having some values dexterity here, but as it moves towards this you will see that it actually comes down to 0. So, neighborhood of this will be having very small value of dexterity and again you will find difficulty in moving the manipulator in this area.

This whole area you will find difficulty because the dexterity has come down and therefore, this will have a difficulty in getting the inverse so the theta dot will keep on increasing as it as it goes close to this area. For getting at different constant velocity if you want this to move with a constant velocity along this path, then you will find it as it passes here this area you will be having difficulty in getting the desired velocity.

And it has to pass through this, then you will decide somewhere here it will stop and you would not be able to pass through that point. So, that is the way how the dexterity measure is used to find out the dexterous workspace of the manipulator. So, any manipulator will be having dexterous workspace, but the dexterity is very high and other spaces where actually dexterity is low we will try to avoid going towards to going that space.

So, the manipulator when you design the manipulator we look at the dexterous workspace and ensure that most of our operations will be done within dexterous workspace when we try to avoid the other workspace for normal operations and if you want to move some other point we also try to avoid the dexterous space and then move or we will plan a path in such a way that the singular space is avoided and then robot is moving to the target.

That is the importance of knowing the dexterity of the manipulator and then as  $J$  is a function of theta you would be able to find out the dexterity I mean dexterity at every point in the workspace and you can make a plot of the dexterous workspace. So, that is the singularity then there is something called boundary singularity. A boundary singularity occurs when the tool tip is on the surface of the work envelop.

That is when you have a workspace, when you have a workplace like this, and the tool tip has already reached here the tool tip has already reached this position then we call as this will not be the right representation. So, the tool tip has already reached this point now this is also a

kind of singularity because if you want to move it in this direction you would not be able to move if you want to give a direction velocity in this direction, then you would not be able to move.

You have actually reached the maximum of that you can reach and then again you have a velocity in this direction you would not be able to give, but you can actually move in this other directions you can move in this direction or this direction, but you cannot move in this direction. So, that is the kind of singularity and that we call it as the boundary singularity of the manipulator.

But we can have it insight that is a interior singularity and when it is at the boundary we call it as boundary singularity and boundary singularity exist for our manipulator you cannot have velocities in particular direction when the manipulators has already reached the boundary. So, that is boundary singularity and the other one is the interior singularity.

(Refer Slide Time: 35:05)

Boundary Singularity of SCARA

$$J = \begin{bmatrix} -l_2 S_1 - l_2 S_{1,2} & -l_2 S_{1,2} & 0 & 0 \\ l_1 C_1 + l_2 C_{1,2} & l_2 C_{1,2} & 0 & 0 \\ 0 & 0 & -1 & 0 \end{bmatrix}$$

$$\text{dex} = \det(J^T J) = (-l_1 S_1 - l_2 S_{1,2})(-l_2 C_{1,2}) - l_2 S_{1,2}(l_1 C_1 + l_2 C_{1,2})$$

$$= l_1 l_2 (S_1 C_{1,2} - C_1 S_{1,2})$$

$$= l_1 l_2 S_2$$

$\text{dex}() = 0$  iff  $S_2 = 0$ ;  $\Rightarrow \theta_2 = 0, \pi$

When  $\theta_2 = 0$ , the arm is fully stretched and the tip is on the surface of the work envelope.

Interior Singularity: Potentially troublesome; formed when two or more axes form a straight line. The effects of rotation about one axis may be cancelled due to a counteracting rotation about the other axis.

Tool configuration may remain the same even though the robot moves in joint space.

Introduction to Robotics 26

Just to tell you to explain you how the boundary singularity is calculated so look at this manipulator for the manipulator where you have a Jacobian like this. So, we saw this Jacobian for the manipulator. Now if you have a Jacobian like this we can find out what is the boundary singularity of this manipulator. What we need to do is find out the dexterity and then see when the dexterity will be 0.

So, we can identify this dexterity as like this it determinant  $J^T J$  and then find out this is the dexterity in terms of the joint angles. So, we will see that  $l_1 l_2 S_2$  is the dexterity

and this will be 0 when  $S_2$  is 0. So, when your  $\sin \theta_2$  is 0 you will be getting dexterity as 0 and that will be the boundary singularity. You can see that when  $\theta_2$  is 0 or  $\pi$  the manipulator will be singular.

So, this is the case for the SCARA robots so we can see that when it is fully extended then it is at the boundary and  $\theta_2$  is 0 it is at the boundary so it is a singular configuration. Similarly, when it is fully closed then it is  $\theta_2$  is  $\pi$  again inside the boundary so again boundary singularity. So, you will see that this  $\theta_2$  is equal to 0 or  $\pi$  is a boundary singularity for the manipulator.

$$J = \begin{bmatrix} -l_1 S_1 - l_2 S_{1-2} & -l_2 S_{1-2} & 0 & 0 \\ l_1 C_1 + l_2 C_{1-2} & l_2 C_{1-2} & 0 & 0 \\ 0 & 0 & -1 & 0 \end{bmatrix}$$

So, this is how we get the boundary singularity of any manipulator. We can actually find out the manipulator boundary similarities by finding out the dexterity when it actually becomes 0 then you will be able to find out the boundary singularities. So, whenever  $\theta_2$  is 0 it is actually a 0 or  $\pi$  then you will be boundary singularity. That is about the boundary singularity and the interior singularity as I mentioned it can actually happen.

It is very troublesome so boundary singularity is not a problem, but interior singularity is a issue. It is formed when two or more axes formed a straight line the effect of rotation about one axis may be cancelled due to counteracting rotation about the other axis. So, this kind of singularities can happen when you have one rotation happening, but other rotations of the joints actually counteracts.

And therefore, even if the joints are moving your tool tip is not moving. So, you have a joint velocity, but you do not see any ovement at the tip of the Cartesian velocity becomes 0 when your joint velocity is still axis that kind of situation also known as the interior singularities. So, the tool configuration may remain same even though the robot moves in joint space.

$$\begin{aligned} dex &= \det(J^T J) = (-l_1 S_1 - l_2 S_{1-2}) \cdot (-l_2 C_{1-2}) - l_2 S_{1-2} (l_1 C_1 + l_2 C_{1-2}) \\ &= l_1 l_2 (S_1 C_{1-2} - C_1 S_{1-2}) \\ &= l_1 l_2 S_2 \end{aligned}$$

$$dex() = 0 \text{ iff } S_2 = 0; \implies \theta_2 = 0, \pi$$

So, the joint space the robot is actually moving, but the tool configuration space no movement is taking place. So, that kind of situations are known as interior singularity.

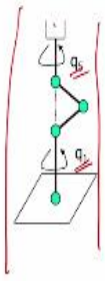

(Refer Slide Time: 38:05)

Example: Microbot-AlphaII

Consider the following locus of points in Joint space  
 $q(\beta) = [q_1, -\beta, 2\beta - \pi, -\beta, q_5]$   $0 < \beta < \pi/2$

If  $a_2 = a_3$  and  $a_4 = 0$ , then  $J(q)$  loses full rank along the line  $q = q(\beta)$  and  $q(\beta)$  represents interior singularities for the articulated robot.

Exercise: For the 3 axis planar robot, show that if  $a_2 = a_1$ , then  $q = [q_1, \pi, q_3]$  is a locus of singularities. Which axes are collinear in this case?

Introduction to Robotics 27

So, let us take this example for the micro robot alpha and then see how the interior singularity happens in this case. So, we can see this configuration of the robots where the robots has actually reached the configuration like this. So, now this the robot joints are actually positioned like this and you will see that this  $q_5$  that is the joint angles are like this  $q_1$  minus  $\beta$   $2\beta$  minus  $\pi$  minus  $\beta$  and  $q_5$ .

So, this is  $q_1$  and this is  $q_5$  so this is  $q_1$  and  $q_5$  and other joints are like minus  $\beta$   $2\beta$  minus  $\pi$  and minus  $\beta$ . So, other 2, 3 joint angles are like this where  $\beta$  is less than  $\pi$  by 2 between 0 and  $\pi$  by 2 and then this situation you will see that even if  $q_1$  is having making an angle and then  $q_5$  is making a opposite rotation then this will actually remains same. There will not be any change in the position and orientation of the end factor even if  $q_1$  and  $q_5$  are making motion that kind of situation is known as interior singularity.

Provided  $a_3$  is equal to  $a_2$  and  $a_4$  is equal to 0 then  $J(q)$  loses full rank along the line  $q$   $\beta$  and  $q$   $\beta$  represents the interior singularities of the articulated robots. So, this kind of situations will arise when it actually aligns in a particular way and I mean the joint angles and the parameter are aligned such a way that you have this situation where the tool tip is not moving even if the joints are moving.

So, that is basically known as the interior singularity so this particular robot has got an interior singularity like this. So, this is an exercise for you for the three axes planar robot show that if  $a_2$  is equal to  $a_1$  and then  $q_1$  pi  $q_3$  is a locus of singularities which axes are collinear in this case? So, try to see how this interior singularity happens and which are the axes that are collinear in this case it is a planar robots and  $a_2$  is equal to  $a_1$ .

So, we will be able to see the situation why it is getting locus of singularities. So, that is the singularities in the manipulator.

(Refer Slide Time: 40:35)

### Generalised Inverses

$\theta = [J(\theta)]^{-1} x$ 

Inverse is not defined when the no. of axes n is arbitrary.

Generalised Inverse: If A is an  $m \times n$  matrix, then an  $n \times m$  matrix X is a generalised inverse of A if and only if it satisfies at least property 1 or 2 of the following list of properties:

1.  $AXA = A$
2.  $XAX = X$
3.  $(AX)^T = AX$
4.  $(XA)^T = XA$

Most well known generalised Inverse is Moore-Penrose Inverse or **Pseudo Inverse ( $A^+$ )** which satisfies all 4 properties. If A is of full rank then,

$$A^+ = A^T (AA^T)^{-1} \quad m \leq n$$

$$= A^{-1} \quad m = n$$

$$= (A^T A)^{-1} A^T \quad m \geq n$$

$J = J(JJ^T)^{-1}$

Introduction to Robotics 28

Now, so we mentioned that whenever there is a J is not invertible because of the position of joints or the joint space values are joint variables are in such a way that the matrix loses its rank. So, that is one situation where actually you can get singularity. Another problem with this inverse J inverse is that when it is non square matrix you will not be able to get the inverse.

So, when it is 6 by 5 matrix, you would not be able to get the inverse of J. So, how do we actually solve this? So, one is that the J loses its rank you do not have an inverse and the other one is J is not a square matrix you do not get a inverse. So, that is the situation where you encounter in the manipulator which are having degrees of freedom other than 6. So, in this case what we need to do is to get an inverse through some other means.

And that is known as the generalized inverse. So, a non-square matrix can be inverted and we can use something called generalized inverse in this case. So, this is defined as a generalized

inverse is defined as if A is an m by n matrix, so if A is m by n matrix, then n by m matrix X is a generalized inverse of A if and only if it satisfies at least property one or two of the following list of properties. So if A is an m by n matrix then we can have X as a m by n matrix as the inverse of A.

1.  $AXA=A$
2.  $XAX=X$
3.  $(AX)^T=AX$
4.  $(XA)^T=XA$

Provided it satisfies at least one or two of this property that is AXA is equal to A and XAX is equal to X. So, if we can actually have a matrix like that X is like that AXA is A and XAX is X then we say X is a generalized inverse of A if it satisfies property one or two of the this that is one or two it satisfies AXA or XAX then we call it as a generalized inverse and therefore once we have that X as a generalized inverse I mean we can have X as a generalized inverse, then we will be able to get the J.

If J is m by n we can find a m by n matrix it satisfy this condition then we will get that as a inverse that is known as the generalized inverse of non square matrix. Now very commonly used generalized inverse is known as Moore Penrose Inverse, Moore Penrose Inverse is known as it is very commonly used generalized inverse and sometimes it is known as the pseudo inverse or we call it as A plus.

$$\begin{aligned}
 A^+ &= A^T (AA^T)^{-1} \quad m \leq n \\
 &= A^{-1} \quad m = n \\
 &= (A^T A)^{-1} A^T \quad m \geq n
 \end{aligned}$$

So, A plus is known as the inverse of pseudo inverse of A so instead of writing A inverse we write it as A plus where it is a pseudo inverse and it satisfies all properties if all properties listed here. So, it actually satisfies all these properties AXA is equal to A XAX is equal to X AX transpose is equal to AX and XA transpose is equal to XA. So, this Moore Penrose Inverse or the pseudo inverse will satisfy all this condition.

And therefore A plus will be a inverse of pseudo inverse of A where A is a non square matrix and how do we get this if A is of full rank condition is that if A is of full rank so it is a rank 5

or rank 7 we will be able to get it as is a full rank then we will see  $A^+$  is given as  $A^T(AA^T)^{-1}A$ . If  $m$  is less than or equal to  $n$  of course if  $m$  is equal to  $n$  then it is  $A^{-1}$  only.

$A^+$  will be  $A^{-1}$  if it is a square matrix it will be same, but if it is  $m$  is greater than  $n$  then  $A^+$  is  $A^T(AA^T)^{-1}A$  or  $A(A^T A)^{-1}A^T$  multiplied by  $A^T$ . So, this is the way how you get the pseudo inverse  $A^+$  so pseudo inverse  $A^+$  can be obtained as either  $A^T(AA^T)^{-1}A$  or  $A(A^T A)^{-1}A^T$  and  $m$  is greater than  $n$ .

So, now you can see what we are doing is we are actually converting this as a square matrix. So  $AA^T$  becomes a square matrix now because  $A$  is not square matrix so  $A^T$  becomes a square matrix and you find the inverse and multiply when you multiply with  $A^T$  or again here you convert that into a square matrix and get the inverse and then multiply with  $A^T$ .

So, this way you will be able to get the pseudo inverse of the manipulator so that is known as  $A^+$ . I hope you got the point so even if the Jacobian is not a square matrix we will be able to get the inverse using the Moore Penrose inverse method or is known as the pseudo inverse so you have  $J$  then  $J^T$  so if you have this inverse is  $J^+$  would be  $J^T(JJ^T)^{-1}J$  if  $m$  is less than or equal to  $n$ . So, that is the way how you get the  $J^+$ .

So, we can always use  $J^+$  and then get the  $\dot{\theta}$  and get the values here. So, non zero matrix is not an issue we will be able to solve it using the pseudo inverse that is the generalized inverse and how we use it for calculating the joint velocities if we know the Cartesian velocity or the tool velocity.

(Refer Slide Time: 47:04)

### Example:

Find the pseudo Inverse of

$$A = \begin{bmatrix} 1 & 0 & 2 \\ 1 & -1 & 0 \end{bmatrix}$$

The rank of A is 2.

$$A^+ = A^T (AA^T)^{-1} \rightarrow A^+ = \frac{1}{9} \begin{bmatrix} 1 & 4 \\ 1 & -5 \\ 4 & -2 \end{bmatrix}$$

#### Resolved Motion Rate Control:

If  $x(t)$  be a differentiable tool configuration trajectory which lies inside the work envelope and which does not go through any workspace singularities, and  $J(q)$  is the  $6 \times n$  tool-configuration Jacobian matrix where  $n \leq 6$ , then the joint space trajectory  $q(t)$  corresponding to  $x(t)$  can be obtained by solving the following non-linear differential equation:

$$\dot{q} = [J(q)^T J(q)]^{-1} J^T(q) \dot{x}$$

Introduced by Whitney in 1969, this method is known as Resolved motion rate Control. The motion in tool-configuration is resolved into joint space components.

### Manipulator Jacobian

#### Analysis of manipulator in static equilibrium

Manipulator Jacobian

So this is just an example for the pseudo inverse. Suppose you have a matrix A it is 2 by 3 matrix. So, m by n m is 2 and n is 3 and the rank is A is 2 it is a full rank that is the rank of the matrix is 2. Now if you want to get the pseudo inverse we use the principle of converting this into a square matrix and then getting the inverse and multiplying with A transpose. So, we will be getting it as A plus is A transpose AA transpose inverse.

$$A^+ = A^T (AA^T)^{-1}$$

So, when you say AA transpose it is 2 by 3 multiplied by 3 by 2 so it will be a 2 by 2 matrix you get the inverse and multiply with A transpose you will be getting it as a 3 by 2 matrix as the inverse. So, A plus will be A will be 2 by 3 and A plus will be a 3 by 2 matrix. So, we

will be getting this as the A plus which is the inverse so it is a 3 by 2 matrix and this is the pseudo inverse of A.

$$A^+ = \frac{1}{9} \begin{bmatrix} 1 & 4 \\ 1 & -5 \\ 4 & -2 \end{bmatrix}$$

So, this is the way how we get the pseudo inverse and then once you have you can use it for getting the doing the calculation of velocities in the case of Jacobian and getting the joint velocities. What is the application of this particular method? So, this is known as the resolved motion rate controlled you will be learning this later. So, in resolved motion rate control you want this manipulator to go with a particular velocity in the Cartesian space.

So, I have Cartesian space and I will say that from this point to this point it should have a particular x dot and y dot. I will say this as x dot and y dot or I will say it should have a constant velocity in one. So, if I have this x dot y dot q1 I want to control the robots and then I want to sent the commands to joint to move so that you will get an x dot and y dot. So, I need to control the joints so I need to control the joint.

So, I would say what should be the joint velocities and that can actually be obtained by J plus x dot. So, I can say that the joint velocity to be calculated based on this and then I comment that velocity I will be getting the robot motion control and that is known as the resolved motion rate controlled. So, if xt be a differentiable tool configuration trajectory which lies inside the workspace and which does not go through any workspace singularities.

$$\begin{aligned} \dot{q} &= [J(q)^T J(q)]^{-1} J^T(q) \dot{x} \\ &= J(q)^+ \dot{x} \end{aligned}$$

And J q is the 6 by n tool configuration Jacobian matrix where n is less than or equal to 6, then the joint space velocity, joint space trajectory qt corresponding to xt can be obtained by solving the non linear differential equation that is you can actually get it q dots is equal to J transpose J inverse J transpose x dots or J q x dot will be q dot so q dot will be J q x dots. So, the trajectory for the joint trajectory can be obtained using this relationship.

And then you move the joints as per the velocity that you calculated. So, this is basically the resolved motion rate control. So, this was introduced by Whitney in 1969 and known as the

resolved motion rate control. The motion and tool configuration is resolved into joint space components that is the resolved motion rate controlled. So, this is the way how we can use the Jacobian.

And its inverse to get the joint trajectory and control the joint manipulator joints in order to get a desired Cartesian velocity and the tool tip. So, that is all for today. We will stop here now we will see how we can actually use the Jacobian or how to compute the Jacobian in both for the linear and angular velocity and how it define a manipulator Jacobian in order to use it for other application apart from the velocity application we can use it for force application also. So, we will see that in the next class. Thank you.
