Module No. #01
Lecture No. #05
Analysis of Linear Time Invariant Dynamical Systems

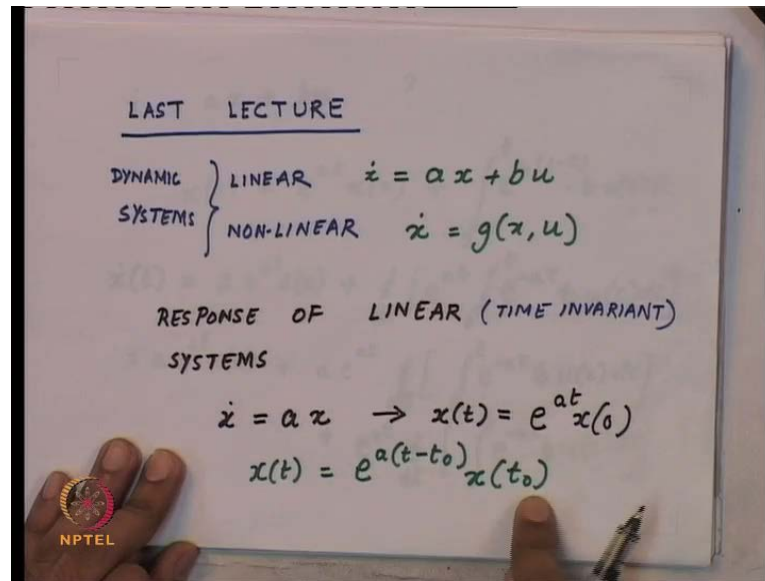

In the previous lecture, we studied the response of certain non-linear system as well as the linear system. In fact, the response which was analyzed was not actually derived I mean none of the you know response of the states. In fact, the speed and the rotor angle in that example, which we did was not derived from first principles I in the linear systems case, we actually kind of guessed the solution. In the non-linear case we guessed how the response would probably be for large disturbances, we did not actually again work out the solution. In fact, it is not possible to do so, in case of a non-linear system.

So, in this particular lecture, we will try to derive the response of linear. In fact, linear time invariant systems, what we shall see is that we can very well characterize the response of linear time invariant system. So, we can say everything about the system you can write down the response of the system. And therefore, you can. In fact, you know go into depth of how the system behaves during transient.

So, this is a very important class of system. In fact, it is a good idea to learn linear systems. So, as to get a kind of feel of how systems behave most systems in the real world are non-linear. But, we can analyze the small disturbance around an equilibrium using linearise analysis like we did in the previous class.

So, in this particular lecture which we have titled as analysis of linear time invariant dynamical systems, what I will do is we shall write down try to find out the response for it is class this linear time invariant set of equations.

(Refer Slide Time: 02:12)

So, let us just review what we did in the previous lecture we considered linear and non-linear systems the general form of a linear system would be like this. In fact, I have written it down as a simple scalar system in the sense that this is just a single variable, we shall generalize this of course. Non-linear systems generally this function on the right hand side is not linear is not a constant coefficient into the state.

So, that is why these systems as I mentioned last time is difficult to write down the response and therefore, analyzing the system becomes a bit tough. Later on, in the course we will of course, learn how to analyze how non-linear as well, but, the analysis tools will be centered around numerical you know solutions of these equations.

But, today I shall show you that for a general linear system of this kind we can actually write down the solution, response of linear time invariant systems, we studied last time was given by, if the system is given by derivative of x with respect to time is equal to ax then this response is simply this. It depends on the initial condition of course, one can verify by taking the derivative of this that it actually satisfies this equation.

So, this is the solution of this set of equations this equation. In fact, if we know the initial condition at a time other than time t is equal to 0 , the solution is this you can easily verify this from by substituting t is equal to t_0 . In that case you will get $x(t_0)$ is equal to $x(t_0)$.

Which is consistent also the derivative of this will satisfy this equation, just one small point that did not actually define time variant system I just told you that this the time invariant system. In fact, there are some systems in which \dot{x} is equal to a , which is the function explicit function of time into x this is also linear system. But, this is a time varying system.

In fact, we will come across some time variant systems later on in our course linear time invariant systems. These normally again are difficult to analyze unlike this system in general. But, of course, there are some special situations in which this also can be analyzed quite easily.

(Refer Slide Time: 04:38)

$$\dot{x} = ax + bu \quad ?$$

$$x(t) = e^{at}x(0) + \int_0^t e^{a(t-\tau)} \cdot b u(\tau) d\tau$$

$$\dot{x}(t) = a e^{at}x(0) + \frac{d}{dt} \left[e^{at} \int_0^t e^{-a\tau} b u(\tau) d\tau \right]$$

$$= a e^{at}x(0) + a e^{at} \int_0^t e^{-a\tau} b u(\tau) d\tau + e^{at} \frac{d}{dt} \left[\int_0^t e^{-a\tau} b u(\tau) d\tau \right]$$

So, more of that later in the course, when we come to synchronous machine modeling. One question which I left you with in the previous class was if the I know the response of \dot{x} is equal to a x , what is the response of \dot{x} is equal to a x plus b u . It turns out that the response is this I will not derive this, but, this is how the response looks like. It is e raise this is whole term which we have seen and in additional convolution term out here. It is an integration of e raise to a t minus τ b u τ d τ remember τ is the variable here in the integration.

So, the integrations carried out with respect to the variable τ you can verify that. In fact, this is indeed the solution this is some something I just wrote down because, if you take \dot{x} of t you take the derivative of this it will be a e raise to a t x 0 plus d by d t of

this term. Now, derivative of this term using the product rule would be a e raise to a t that is derivative of the first term into this plus e raise to a t into the derivative of this.

(Refer Slide Time: 06:11)

$$\begin{aligned} \therefore \dot{x}(t) &= a \left[e^{at} x(0) + \int_0^t e^{a(t-\tau)} b u(\tau) d\tau \right] \\ &\quad + e^{at} \cdot e^{-at} b u(t) - \underline{\underline{\pi}} \\ &= a x + b u \end{aligned}$$

ALSO VERIFY THAT

$$\begin{aligned} x(t) \Big|_{t=0} &= e^{0 \cdot t} x(0) \\ &= x(0) \end{aligned}$$

So, that yields \dot{x} is equal to $a x$ plus $b u$. In fact, a is taken out common out of that plus this second term. So, this is the first term and this is the second term. So, you add these two up. The second term of course, is e^{at} into e^{-at} into $b u(t)$, see remember look at this derivative this final value is t . And if you take the derivative of this with respect to t just the integrand is basically obtained at time t , at the time t .

So, basically you will get this which is x plus $b u$. So, what I wanted to show you that this is indeed a solution of this. So, just a minor point here that in case you have got a linear system with an input you can still get a , you can still write down the answer. If you know u the behavior of u of t you can actually write down this answer.

(Refer Slide Time: 07:22)

The image shows a handwritten derivation on a piece of paper. At the top, the differential equation is written as $\dot{x} = ax + bu$ with a question mark. Below it, the solution is given as $x(t) = e^{at}x(0) + \int_0^t e^{a(t-\tau)} \cdot bu(\tau) d\tau$. The next line shows the derivative of this solution: $\dot{x}(t) = a e^{at}x(0) + \frac{d}{dt} [e^{at} \int_0^t e^{-a\tau} bu(\tau) d\tau]$. The final line shows the result of applying the product rule: $\dot{x}(t) = \{ a e^{at}x(0) + a e^{at} \int_0^t e^{-a\tau} bu(\tau) d\tau + e^{at} \frac{d}{dt} [\int_0^t e^{-a\tau} bu(\tau) d\tau] \}$. An NPTEL logo is visible in the bottom left corner of the paper.

So, having an input poses no particular or major problem as far as linear time invariant systems are concerned, we can also verify of course. That if I evaluate x of t at τ using this formula, using this formula you plug in t is equal to 0 here, you will get $x(0)$ because this term becomes equal to 1. And if you put the upper limit of the integration also $x(0)$ this term will become 0.

(Refer Slide Time: 07:53)

The image shows handwritten notes on a piece of paper. At the top, the title "RESPONSE OF HIGHER ORDER COUPLED SYSTEMS" is written and underlined. Below the title, the differential equation $\dot{x} = Ax$ is written. An example is given as $\text{eg: } \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$. Below the matrices, arrows point from the terms \dot{x} , A , and x to their respective positions in the equation. An NPTEL logo is visible in the bottom left corner of the paper.

So, it is just its consistent x of t at t is equal to 0 is x of 0. So, as I mentioned some time back, we have kind of verified that this is in fact, the solution of this. So, this was one

problem which I had mentioned last time. Now, let us get back to the original problem which we had set out to solve in the last class that is the response of higher order linear time invariant, but, coupled systems.

(Refer Slide Time: 08:04)

$$\begin{cases} \dot{x}_1 = a_{11}x_1 \\ \dot{x}_2 = a_{22}x_2 \end{cases} \quad \left\{ \begin{array}{l} x_1 = e^{a_{11}t} x_1(0) \\ x_2 = e^{a_{22}t} x_2(0) \end{array} \right.$$
$$\begin{cases} \dot{x}_1 = a_{11}x_1 + a_{12}x_2 \\ \dot{x}_2 = a_{21}x_1 + a_{22}x_2 \end{cases}$$

TRANSFORMATION

If you recall in the previous class, we had given you this example \dot{x}_1 is equation $a_{11}x_1$, \dot{x}_2 is equal to $a_{22}x_2$ this is the second order system, but, it is not coupled. So, you get a very simple solution here, it is a very simple solution you just take the individual solutions for the states.

But, if you get a two slightly more complicated scenario where there is some coupling this is the second order coupled system you can of course, have third order and tenth order hundredth order systems also. But, we will limit ourselves to a simple situation, this is the second order coupled system.

(Refer Slide Time: 08:39)

RESPONSE OF HIGHER ORDER
COUPLED SYSTEMS

$$\dot{x} = Ax$$

eg:
$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

↑ ↑ ↑
 \dot{x} A x

So, we write this second order coupled system as \dot{x} is equal to Ax , where A is a matrix this A matrix has terms a_{11} a_{12} a_{21} a_{22} . So, this x is in fact, made out of two components it is a vector, it is still a linear system but, a coupled system. Now, how do you solve this system I mentioned in the, I gave you a very simple example in the previous class. In which I could really get the response by using the idea of a transformation.

Now, a transformation is the extremely important idea in engineering analysis. In fact, you must have come across various kinds of transformation like Laplace transformation. In fact, taking a logarithm of a product of two terms, then adding the two logs of the individual terms. And then taking the antilog is actually a kind of a transformation approach to do a multiplication.

So, you are transforming it into new variables doing an operation in the new variables and getting back to the old variable. So, this is the basic idea of any transformation what we shall actually now, learn in this particular system is how we can use a linear transformation.

In fact, this is a very simple kind of transformation we are going to study here, how you use a linear transformation. To transform these variables two new variables in which the dynamical equations are very easy to solve. So, that is what we will try to do.

(Refer Slide Time: 10:12)

TRANSFORMATIONS

$$\begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}$$

↑ P ↑ y

∴

$$P \dot{y} = A P y$$
$$\therefore \dot{y} = P^{-1} A P y \quad \left. \vphantom{\dot{y}} \right\} \text{DYNAMICAL EQNS OF NEW VARIABLE}$$

So, suppose I if I got this coupled linear system. Let us, define a transformation of variables this is a linear transformation of variables I will just read it out x_1 and x_2 are related to y_1 and y_2 by this transformation, that is x_1 is equal to $p_{11} y_1$ plus p_{12} into y_2 , x_2 is equal to $p_{21} y_1$ plus p_{22} into y_2 . So, this is the transformation of variables. So, what I wish to achieve will become very clear in sometime.

So, I substitute for x in this equation. So, what I will have is p of y dot, remember p is a constant matrix in this particular case we shall of course, learn later on some very interesting transformations which are time variant. But, right now we are talking about linear time invariant systems and we shall use a time transformation which is not time dependent, it is just a constant matrix.

So, if you have got $p y$ dot it will be equal to $a p y$ that is because of substituted for x here as well as x here p is not a function of time. So, your derivative is simply $p y$ dot. So, in terms of the new variables y dot is equal to p inverse $a p$ into y . So this, what I achieved in the new variable. So, these are the dynamical equations of the new variable. (No audio from 11:27 to 11:36) The whole point in doing a transformation of course is that if this system is simpler I can solve for this system. And then somehow get back to x_1 and x_2 .

So, what I intend to do is solve for y and get back now of course, if this is the coupled matrix. Suppose, this is has got non 0 terms here here here and here. Obviously, we

are not really doing, we are not really simplifying the problem at all I mean you are back to the old problem.

(Refer Slide Time: 12:25)

$$P^{-1} A P = \Lambda = \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix}$$

$$\dot{y} = P^{-1} A P y = \Lambda y$$

$$y = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} e^{\lambda_1 t} & 0 \\ 0 & e^{\lambda_2 t} \end{bmatrix} \begin{bmatrix} y_1(0) \\ y_2(0) \end{bmatrix}$$

$$x = P y = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} \begin{bmatrix} e^{\lambda_1 t} & 0 \\ 0 & e^{\lambda_2 t} \end{bmatrix} \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}^{-1} x(0)$$

has to exist ←

But, a very nice situation occurs if p inverse a p is diagonal. So, if I chosen my p in a certain way now that way of course, will try to derive a bit later. But, if I chosen my p in such a way such that this is diagonal, that is p inverse $A P$ is a diagonal matrix, that is it is made out of terms $\lambda_1 \lambda_2 0 0$, which still do not know what this p is what this λ_1 and λ_2 are. But, let us assume you have this p which will take you to this form.

So, what you have is y will be equal to, simply equal to e raise to $\lambda_1 0$ that the coupling, there will be complete decoupling between y_1 and y_2 why is this. So, basically we have got to this form in some sense they have got a complete decoupling the solution becomes very simple.

(Refer Slide Time: 13:25)

The image shows a whiteboard with handwritten mathematical equations. At the top, a system of two decoupled first-order differential equations is written in matrix form:
$$\begin{bmatrix} \dot{y}_1 \\ \dot{y}_2 \end{bmatrix} = \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}$$
 Below this, the general solutions for each equation are given:
$$y_1 = e^{\lambda_1 t} y_1(0), \quad y_2 = e^{\lambda_2 t} y_2(0).$$
 An arrow points from the matrix in the first equation to the expression $P^{-1}AP$ written below it, indicating that the matrix is diagonalized. In the bottom left corner of the whiteboard, there is a small circular logo with the text "NPTEL" below it.

So, the point is if your dynamical equations are \dot{y} is equal to $P^{-1}AP y$, which is nothing, but, y_1 and y_2 get completely decoupled. In fact, I will just rewrite this here, you will have y_1 and y_2 . (No audio from 13:27 to 13:34) this is $P^{-1}AP$. Suppose, it is possible to have $P^{-1}AP$, which will give you this. So, the solution becomes very very simple it becomes simply y_1 is equal to $e^{\lambda_1 t} y_1(0)$ and y_2 is equal to $e^{\lambda_2 t} y_2(0)$ because, there is a complete decoupling.

So, this is what. In fact, I have got here I have written it down in matrix form this is the solution. So, if I manage to get $P^{-1}AP$ to be diagonal, then you will find that your solution is very simple. So, you have got your solution in terms of y of course, you have to get the final solution of x . So, how do I get x from y is $x = P y$. So, my solution of x will be simply this P into y . Now, y consist of $y_1(0)$ and $y_2(0)$. In fact, $y(0)$ is nothing, but, $P^{-1}x(0)$ because x is equal to $P y$.

So, the point is we will just circle this actually follows from this. So, $y_1(0)$ is actually $P^{-1}x(0)$. So, this is this and this is in fact, this whole term here is actually this. So, one of the we of course, come across one important feature here, that if we are going to get P^{-1} its inverse should exist. So, this P matrix has to be invertible.

So, the transformation x is equal to $P y$ should be invertible or in other words in layman terms, what you would say is that you can go from x to y , but, you should also be able to come from y to x and vice versa, if you know y you get x and if you know x you

should be able to get y . If that is true then you can use this transformation and get this solution.

(Refer Slide Time: 15:51)

$$\dot{y} = P^{-1} A P y = \hat{\Lambda} \dot{y}$$

$$P^{-1} A P = \hat{\Lambda} = \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix}$$

$$y = \begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} e^{\lambda_1 t} & 0 \\ 0 & e^{\lambda_2 t} \end{bmatrix} \begin{bmatrix} y_1(0) \\ y_2(0) \end{bmatrix}$$

$$y(0) = P^{-1} x(0)$$

$$x = P y = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} \begin{bmatrix} e^{\lambda_1 t} & 0 \\ 0 & e^{\lambda_2 t} \end{bmatrix} \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}^{-1} \begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix}$$

has to exist ←

Of course, one important point which I have actually not discussed here is this presumes that for any A you are going to get some P which will diagonalise this matrix, this is in general not true. In fact, there will be situations where you cannot diagonalise a matrix A using any such P . So, this is one important point which you should just keep at the back of your mind. This is not always possible you cannot always get a P such that you can diagonalise this, this will become clear when we actually derive the expression for P .

(Refer Slide Time: 16:53)

The image shows a whiteboard with handwritten mathematical equations. The first equation is a vector equation for $x(t)$ in terms of initial conditions $x(0)$ and a matrix exponential. The second equation is a similar vector equation with a different matrix exponential. Below these, the text '2 'modes' or patterns' is written. The final equation shows the relationship between the modal matrix Q and the eigenvector matrix P .

$$\begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} = \begin{bmatrix} p_{11} \\ p_{21} \end{bmatrix} e^{\lambda_1 t} \begin{bmatrix} q_{11} & q_{12} \end{bmatrix} \begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix} + \begin{bmatrix} p_{12} \\ p_{22} \end{bmatrix} e^{\lambda_2 t} \begin{bmatrix} q_{21} & q_{22} \end{bmatrix} \begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix}$$

2 'modes' or patterns

$$\begin{bmatrix} q_{11} & q_{12} \\ q_{21} & q_{22} \end{bmatrix} = \begin{bmatrix} p_{11} & p_{12} \\ p_{21} & p_{22} \end{bmatrix}^{-1}$$

NPTEL

So, what is the solution of x ? So, if you look at x this is what I get. So, I just expand this if I expand this. This is what I will get p_{11} it is just expanding that term here. So, you if you look at this carefully I just expand this. So, what I will get is $p_{11} p_{21} e^{\lambda_1 t}$ into $q_{11} q_{12}$, where $q_{11} q_{12}$ is in fact, this row matrix is in fact, the first row of p inverse. So, what you will get is by expanding this you will get this.

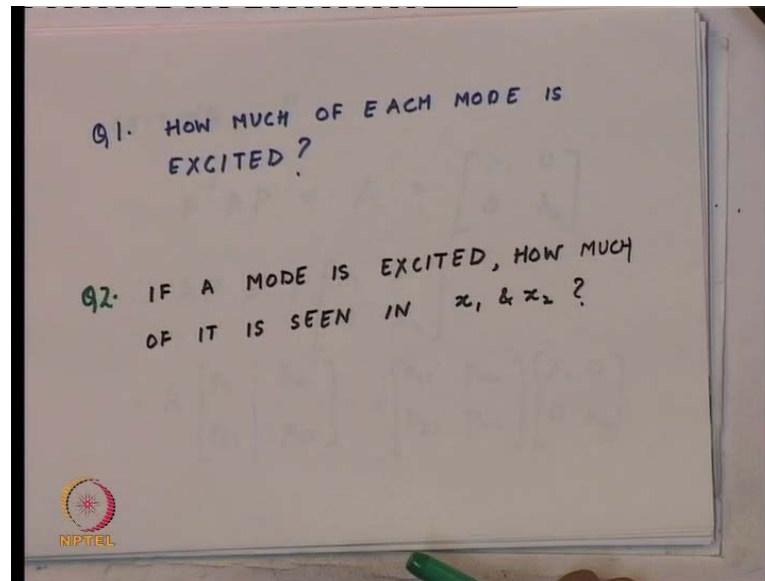

So, what you find it in a second order system in which that A matrix is diagonalizable, what you will see is that your response is consisting of two terms and if you look at a time varying part of these terms. In fact, they are telling you something. In fact, they are telling you two modes are patterns exist in the response.

So, if you look at the response of x_1 in general as long as p_{11} is not equal to 0, x_1 will contain $e^{\lambda_1 t}$ and $e^{\lambda_2 t}$ kind of term $e^{\lambda_1 t}$ $e^{\lambda_2 t}$ kind of terms also. That is of course, provided p_{11} and p_{12} are non 0.

And also you will find that of course, this also presumes that this product here of this row matrix and this column is non 0. If this product becomes 0 then of course, this whole term will not exist. So, you will, this term whole term will not exist, in case this product here becomes equal to 0. Similarly, if this product becomes equal to 0 this pattern will not exist. So, this you know response is consisting of two patterns. So, x_1 consist of two patterns $e^{\lambda_1 t}$ $e^{\lambda_2 t}$ it will have two kinds of terms.

So, this very loosely speaking this particular thing is called a mode. So, this is one mode this is another mode. So, 1 thing you just remember in case of linear systems linear time invariant system, your response is a super position of modes. Modes are terms which have got this $e^{\lambda t}$ kind of response. Remember in this particular solution q_1 and q_2 is in fact, defined in this fashion it is the inverse of the p matrix.

(Refer Slide Time: 19:32)

So, this q is in fact, the inverse of the p matrix and these are in fact terms of this. So, we can directly ask a question that if you have got an a matrix which is diagonalizable your really having modes. In fact, if it is a second order system you have a got a two modes corresponding to λ_1 and λ_2 of course, I will retreat here. That we are assuming that the A matrix is diagonalise diagonalizable by some transformation P inverse $A P$.

So, we this is an assumption we will make, we will relax subject later. So, the question once we get this response is how much of this term is visible in x_1 ? How much of this term is existing in x_2 .

(Refer Slide Time: 20:18)

$$\begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} = \begin{bmatrix} P_{11} \\ P_{21} \end{bmatrix} e^{\lambda_1 t} \begin{bmatrix} q_{11} & q_{12} \\ q_{21} & q_{22} \end{bmatrix} \begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix} + \begin{bmatrix} P_{12} \\ P_{22} \end{bmatrix} e^{\lambda_2 t} \begin{bmatrix} q_{21} & q_{22} \end{bmatrix} \begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix}$$

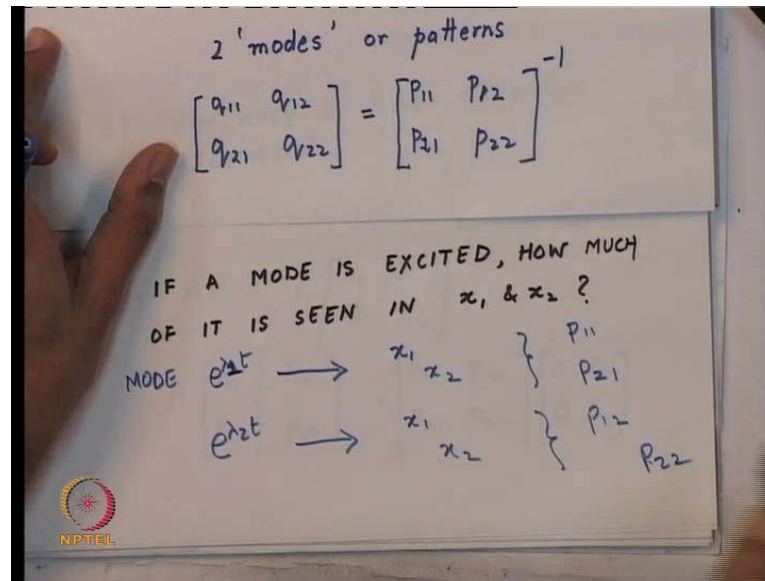

2 'modes' or patterns

$$\begin{bmatrix} q_{11} & q_{12} \\ q_{21} & q_{22} \end{bmatrix} = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix}^{-1}$$

If you look at this particular response of the system this is a number. This is a row matrix which is in this case 2 into 1 this is 1 into 2. So, what you will get is this is a number, this number is common to these two states. So, the two states for the two states these this particular number is common, but, you notice that p_{11} and p_{21} in general can be different in general it could they could be different. So, the amount of a mode if it is excited visible in x_1 and x_2 is defined by this p_{11} and p_{21} .

So, for example, if p_{21} is very small, we would say that this particular mode is not observable in x_1 . Similarly, if p_{12} very small, we said that this particular mode is not observable in x_2 . But, in general you will see that p_{11} and p_{21} are non 0, I mean for most systems which you will encounter.

(Refer Slide Time: 21:23)

So, the first question which rather the second question which is asked here, if a mode is excited how much of it is seen in x_1 and x_2 . So, if the mode corresponding to the Eigen, corresponding to $e^{\lambda_2 t}$ for the mode, $e^{\lambda_1 t}$ sorry, x_1 and x_2 are excited in the are seen in the ratio p_{11} and p_{21} , for the mode $e^{\lambda_2 t}$ the relative magnitudes of this term as seen in x_1 and x_2 are in the ratio p_{12} and p_{22} .

So, this p_{11} and p_{22} in fact, tell you how much of a particular mode is observable in a particular state. Remember in a coupled system there is no 1 to 1 correspondence between a mode and a state in general, in a particular the response of a particular state you will see both these terms appearing that two modes. The first question which I have asked here is how much of each mode is excited that depends on this product.

So, for example, if this product here turns out to be 0 this mode is not excited at all and will not be seen in either of these states, got what I am saying. So, similarly, if this product is 0 this and this it turns out to be 0, in that case you will not see this particular part or this pattern in this response.

So, this an important point which you should note, that the components of the inverse of this p matrix and the initial conditions determine, the extent to which a pattern or a mode is excited, if a mode is excited the amount it is observable in a particular state depends on this p_{11} and p_{21} .

(Refer Slide time: 23:39)

RESPONSE OF HIGHER ORDER
COUPLED SYSTEMS

$$\dot{x} = A x$$

eg:
$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

\uparrow \uparrow \uparrow
 \dot{x} A x

So, before we move ahead let us just get back to where we were for a moment, we are starting off with a coupled system. This was our coupled system, we defined a transformation, we assume that this transformation would simply things in the sense that the equations in the new variables would be easy to solve. So, we have got p inverse A P is diagonal. This is assume that you have a P which will make you diagonal, if a diagonal y 1 and y 2 equations get decoupled the solution becomes very very simple.

Y 1 is equal to this, y 2 is equal to e raise to lambda 2 into y 2 to get back the original variables x you have to retransform this and get back to the original variable. So, you have to use the inverse transformation here. So, it is p e raise to the this particular matrix into p inverse into the initial conditions. So, the generalized response of course, can be written in this fashion, the components of p, the columns of p in some sense the columns of p determine the relative observability of a certain mode. The inverse components or the inverse of p and the initial conditions determine how to what extend the mode is excited.

(Refer Slide Time: 25:07)

GETTING P

$$P^{-1}AP = \Lambda = \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix}$$
$$\therefore AP = P \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix}$$
$$\therefore A \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} = \begin{bmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{bmatrix} \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix}$$

So, the product of this will determine the overall strength of this particular mode is that ok. So, the whole question now boils down to how do you get this p remember p is such that p inverse A P is a diagonal matrix. So, what we have is just premultiplied by p you will get A P is equal to this. Suppose, p is of course, a matrix i kind of partition it into two columns, these are two columns when if you carry out this product you will get effectively two equations. If you just equate this matrix which comes here, with this matrix will in fact, get two equations this, this is, the first column of this left hand side will become a p 11, a into this column the second column becomes a into this column.

(Refer Slide Time: 26:10)

$$A \begin{bmatrix} P_{11} \\ P_{21} \end{bmatrix} = \lambda_1 \begin{bmatrix} P_{11} \\ P_{21} \end{bmatrix} \quad \checkmark$$
$$\propto A \begin{bmatrix} P_{12} \\ P_{22} \end{bmatrix} = \lambda_2 \begin{bmatrix} P_{12} \\ P_{22} \end{bmatrix} \quad \checkmark$$

Eigenvalues & right eigenvectors.

So, if we actually work it out, you will actually get two equations the two equations. In fact, you must have done a course in mathematics in your undergraduate years, you would realize that this lambda 1 and lambda 2 are nothing but, what you have learned is called the Eigen values of the matrix a. And the columns of t are the corresponding Eigen vectors. So, this p 11 p 21 is in fact, the right Eigen vector corresponding to this Eigen value lambda 1. Of course, we still have not got what this lambda, lambda 1 lambda 2 and this matrix p are.

(Refer Slide Time: 27:08)

Handwritten notes on a whiteboard:

$$\therefore (A - \lambda I) \begin{Bmatrix} p_{11} \\ p_{21} \end{Bmatrix} = 0$$

↑
column of P.

$\begin{Bmatrix} p_{11} \\ p_{21} \end{Bmatrix}$

Trivial $\rightarrow \begin{Bmatrix} p_{11} \\ p_{21} \end{Bmatrix} = 0 \rightarrow$ NOT ACCEPTABLE

↑
if $(A - \lambda I)$ is nonsingular

$\therefore \det(A - \lambda I) = 0$ characteristic equation.

NPTEL

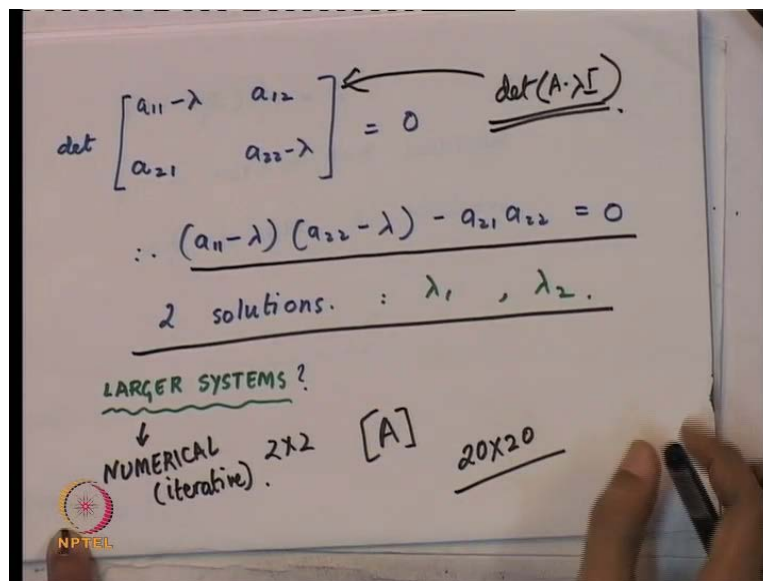

So, our next step is find out what these things are. So, if you look at this particular equation either lambda 1 or lambda 2 equation, you will find that you get this on to the right hand side for both lambda 1 and lambda 2, you will get an equation of this kind where p is nothing, but, a column of p. So, for example, I can p 11, p 1 will be p 11 p 21. So, p 1 is the right diagonal vector corresponding to the Eigen value lambda 1. This is nothing, but, p 1.

So, what you have here is. So, now, the question comes are we in a position to get what lambda or what are the Eigen values and the Eigen vector this is true for every Eigen value and Eigen vector and the corresponding every Eigen and the corresponding Eigen vector. Now, obviously, if a minus lambda i is in fact, invertible that is this is non singular one of the solutions, we can get for this column of p is 0, it is a 0 vector. In fact, I should write it this way for 2 by 2 systems this p will be 0.

But, this is not acceptable, why is it not acceptable? Because, I have told you that a transformation should be such that p inverse has to exist. So, we cannot have one column or both columns equal to zero then you cannot take out inverse and you cannot get the solution finally, in terms of x .

So, you really cannot this particular trivial solution is not of any use. So, this particular solution is not of any use to us what we should look for is solutions in which p is non 0. In fact, the only way you can have p non 0 is to have this singular. So, this is singular it is possible to have solutions of p , this column p which are non 0. In fact, this is also, this is a vector this column vector. So, this is an important condition which you should have in order to obtain non trivial solutions for p . So, in fact, if you look at this equation this itself in fact, aids you to obtain the Eigen values and Eigen vectors of the system.

(Refer Slide Time: 29:25)

So, if you look at for example, this particular system. So, I have done this is nothing, but, determinant the left hand side is nothing, but, determinant of a minus lambda i. So, this is what I have really done here. So, determinant of a minus lambda is equal to 0. So, in this 2 by 2 system, we will get this particular equation and it has got two solutions which you can actually solve for lambda 1 and lambda 2. So, if I know a_{11} a_{22} a_{12} and a_{21} that is the a matrix I can get what lambda 1 and lambda 2 are going to be.

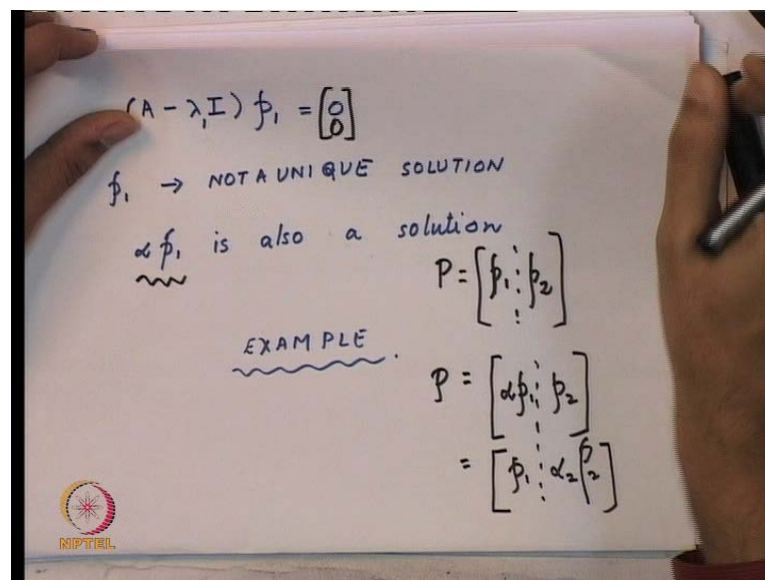

So, actually you can solve for lambda 1 and lambda 2 in this particular case of course, we have only considered 2 into 2 system this a matrix is a 2 into 2 system. If you have

got say a 20 by 20 system that is containing twenty states which are coupled together using a 20 by 20 state matrix or the same matrix. In that case you will get this a polynomial of this kind of order 20 when you apply this determinant of a minus lambda is equal to 0. But, remember it may not be easy to solve for this lambda 1 and lambda 2 that way.

See if you are going to second order solution this is quadratic you can get values of lambda 1 and lambda 2 from these. If you have got forth order system you get a quatic equation in lambda once you actually evaluate this determinant. But, beyond a point you cannot actually solve you cannot get the answer directly for the various lambda. So, for larger systems you will use some kind of numerical techniques to obtain the Eigen values and the Eigen vectors.

So, this is just a caution here, that although for the second order system I can actually solve this quadratic to get lambda 1 lambda 2 in a large system. You have to think of some special numerical techniques in order to get lambda 1 and lambda 2 numerical and the iterative techniques to obtain, the Eigen values and Eigen vectors.

(Refer Slide Time: 31:42)

So, now we are at a point where we can actually tell you how to proceed. If you have got an a matrix compute this the Eigen values of the a matrix. Once you get the Eigen values of the a matrix you can compute, what p the columns of the p matrix are. In fact, they will be the right diagonal vectors corresponding to the Eigen values.

So, if you look at this particular equation which defines what p is for example, if I want to find out what is p you will do $(A - \lambda I)v = 0$. Since, by definition λ is a value for which this determinant becomes 0 after all we found out λ by taking the fact that determinant of $(A - \lambda I)$ is equal to 0. This you cannot get the value of p this is of course, again I should write it as a vector, you cannot get the value of p by simply taking the inverse because this is not going to be $(\)^{-1}$.

So, what you have to do is you have to you cannot of course, get a unique solution for p . So, you will have to actually assume one component of p to be say 1 and get the other component from this equation. Now, this may be a bit unclear at this particular point of time, we will do a simple example in which we will try to tell you how to get this p once you have got the Eigen values.

Remember one thing that if you know p then αp is also a solution. So, if I get a p then αp is also a solution. So, the Eigen vectors are not unique you can always form P matrix. Suppose, your P matrix you have found from the columns p_1 and p_2 .

Then this also is an Eigen vector matrix and this also is. (No audio from 33:34 to 33:40)
So, what we see here is that there is no uniqueness as far as this p is concerned. So, Eigen vectors in some sense are direction vectors the magnitude of it is not unique. So, just remember this point whenever we are going to solve this that is not going to be a unique value of p . So, the best way to actually understand this you have done a lot of manipulations the simple arithmetic type manipulations a simple way to understand it is using an example.

(Refer Slide Time: 34:22)

Handwritten equations on a whiteboard:

$$\left. \begin{aligned} \dot{x}_1 &= x_1 + 0.5x_2 \\ \dot{x}_2 &= 0.5x_1 + x_2 \end{aligned} \right\}$$
$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} 1 & 0.5 \\ 0.5 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$
$$\rightarrow \dot{x}_1 - \dot{x}_2 = 0.5x_1 - 0.5x_2$$
$$\rightarrow \dot{x}_1 + \dot{x}_2 = 1.5x_1 + 1.5x_2$$

The NPTEL logo is visible in the bottom left corner of the whiteboard image.

So, if you recall in the previous class we had done a simple example for a coupled system. So, if you recall this is what the system was \dot{x}_1 is equal to x_1 plus $0.5x_2$ \dot{x}_2 is equal to $0.5x_1$ plus x_2 and this was my system.

(Refer Slide Time: 34:40)

Handwritten equations on a whiteboard:

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} = \begin{bmatrix} 1 & 0.5 \\ 0.5 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

\uparrow
 A

$$\det \begin{bmatrix} 1-\lambda & 0.5 \\ 0.5 & 1 \end{bmatrix} = \det(A - \lambda I)$$
$$= 0$$

The NPTEL logo is visible in the bottom left corner of the whiteboard image.

So, I will just rewrite this.

(No audio from 34:38 to 34:58)

This is my A matrix now, how do I define the Eigen values of this matrix determinant of a minus lambda i. So, lambda i is nothing, but. So, this is equal to determinant of A minus lambda I. I in fact, is the I did not mention it before, it is the identity matrix.

(Refer Slide Time: 35:38)

$$\det \begin{bmatrix} 1-\lambda & 0.5 \\ 0.5 & 1-\lambda \end{bmatrix} = \det(A - \lambda I)$$

$$= 0$$

$$(1-\lambda)^2 - 0.5 \times 0.5 = 0$$

$$\lambda^2 - 2\lambda + 1 - 0.25 = 0$$

$$\lambda^2 - 2\lambda + 0.75 = 0$$

So, this should be equal to 0. So, this what it should be. So, what we have is when you take out this determinant, you will get 1 minus lambda square minus 0.5 into 0.5 is equal to 0. So, we will get lambda square minus 2 lambda plus 1 minus 0.25 is equal to 0. So, this is something lambda square minus 2 lambda.

(Refer Slide Time: 36:16)

$$\lambda^2 - 2\lambda + 0.75 = 0$$

$$\Rightarrow (\lambda - 0.5)(\lambda - 1.5) = 0$$

$$\lambda_1 = 0.5$$

$$\lambda_2 = 1.5$$

$$\begin{bmatrix} 1-0.5 & 0.5 \\ 0.5 & 1-0.5 \end{bmatrix} \vec{p}_1 = 0$$

$$\uparrow (A - \lambda_1 I)$$

So, we have got lambda square minus 2 lambda, that implies we can guess that the solution is (No audio from 36:27 to 36:35) sorry right 0.5 yeah so, this is the solution. So, your two Eigen values are. So, for a second order system you have got a two Eigen values which is this. Now, once you have got these Eigen values you have to take out the Eigen vectors.

So, what are the Eigen vectors by definition, let us take out the Eigen vector p 1 that is corresponding to this lambda 1. So, what you will have is A is this A minus lambda I is nothing, but. So, this is nothing, but, A minus lambda I of course, this is singular you will get 0.5 0.5 0.5 here.

(Refer Slide Time: 37:40)

$$\begin{bmatrix} 0.5 & 0.5 \\ 0.5 & 0.5 \end{bmatrix} p_1 = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

↑
'P'

$$\begin{bmatrix} 0.5 & 0.5 \\ 0.5 & 0.5 \end{bmatrix} \begin{bmatrix} p_{11} \\ p_{21} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

let $p_{11} = 1$

$$0.5 \times 1 + 0.5 p_{21} = 0$$

$$\Rightarrow p_{21} = -1$$

So, what we have here is.

So, we can get the value of p 1, but, the by if we cannot of course, invert this is not possible to invert this matrix because it is singular. So, how to get the value of p 1 remember that p 1 is nothing, but, p 11 it is a column of the matrix P. So, the point is now how do you get the value of p 11 and p 21? You cannot get it unless you fix some 1 particular variable. So, for example, I can fix p let us try do try to do this, let us fix p 11 there is no unique solution of p 11 or p this p 1. So, there is no way I can actually get this p 11 and p 21 uniquely.

So, what I will do is that I will fix this particular value here, let us just try it out. So, I will fix this value of p_{11} . So, we could just as well have fixed the value of p_{21} . But, I have chosen the value of p_{11} . So, if you take p_{11} as 1 then you will get 0.5 into 1 plus 0.5 into p_{21} is equal to 0 , which also means that p_{21} should be equal to minus 1 .

(Refer Slide Time: 39:35)

Handwritten work on a whiteboard:

$$p_1 = \begin{bmatrix} 1 \\ -1 \end{bmatrix} \rightarrow \lambda_1 = 0.5$$

$$\begin{bmatrix} 0.5 & 0.5 \\ 0.5 & 0.5 \end{bmatrix} \begin{bmatrix} p_{11} \\ p_{21} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1-1.5 & 0.5 \\ 0.5 & 1-1.5 \end{bmatrix} \begin{bmatrix} p_{12} \\ p_{22} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$\uparrow A - \lambda_2 I$

So, what we have got is p_{11} is equal to 1 and minus 1 . So, 1 and minus 1 this is 1 Eigen vector corresponding to the Eigen value λ_1 is equal to 0.5 . I can of course, make this 2 and minus 2 , that is also acceptable you will find that 2 minus 2 also satisfies this equation.

So, there is nothing unique about the Eigen vector as you can always multiply it by constant and still is an Eigen vector. What about p_2 ? p_2 is.

(No audio from 40:05 to 40:28)

So, this is nothing, but, a minus $\lambda_2 I$. Again we cannot get unique solutions of p_{21} and p_{12} and p_{22} . So, what we will do is we will just freeze p_{12} at 1 in that case you will get.

(No audio from 40:45 to 41:03)

So, what we have is, the Eigen vector corresponding to the Eigen value 1.5 is in fact, 1 sorry and both are plus 1 .

(Refer Slide Time: 41:27)

$$\begin{bmatrix} x_1(t) \\ x_2(t) \end{bmatrix} = \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{+0.5t} k_1 + \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{t} k_2$$

\uparrow β_1 \uparrow β_2

$$k_1 = \begin{bmatrix} q_{11} & q_{12} \end{bmatrix} \begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix}$$

So, what we have is the general solution this particular system is going to be.

(No audio from 41:27 to 41:50)

This is the first Eigen value there is something else to be written here, we will just do that presently there is one term I will call it k_1 .

(No audio from 42:00 to 42:19)

(Refer Slide Time: 42:40)

$$k_2 = \begin{bmatrix} q_{21} & q_{22} \end{bmatrix} \begin{bmatrix} x_1(0) \\ x_2(0) \end{bmatrix}$$
$$P = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \quad PP^{-1} = \frac{1}{2} \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}$$
$$P^{-1} = \frac{1}{2} \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix} \Rightarrow \begin{bmatrix} q_{11} & q_{12} \\ q_{21} & q_{22} \end{bmatrix}$$

k 1 is nothing, but.

(No audio from 42:24 to 42:39)

And k 2 is (No audio from 42:41 to 42:51) now, this q 11 in fact, is the row of, the inverse of the p matrix or p matrix is made out of the columns p 1 and p 2. So, what are the columns p 1 and p 2 1 minus 1 1 and 1. So, p inverse is equal to half of we take out a determinant (No audio from 43:20 to 43:29) right. Just check whether it is we can just do p p inverse that will be 1 into 1 this is 1 into minus 1 it will come 0. So, this cannot be here this has to be here. So, 1 into 1 that will be 1 that 1 so, this is 2 this is 0 0 is 2. So, p inverse is indeed this, this is nothing but, (No audio from 44:07 to 44:14) the q matrix. So, what we have here is for the final solution.

(Refer Slide Time: 44:26)

$$\begin{bmatrix} z_1(t) \\ z_2(t) \end{bmatrix} = \begin{bmatrix} 1 \\ -1 \end{bmatrix} e^{0.5t} \frac{1}{2} \begin{bmatrix} 1 & -1 \end{bmatrix} \begin{bmatrix} z_1(0) \\ z_2(0) \end{bmatrix} + \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{1.5t} \frac{1}{2} \begin{bmatrix} 1 & 1 \end{bmatrix} \begin{bmatrix} z_1(0) \\ z_2(0) \end{bmatrix}$$

Let me just write it down is nothing but.

(No audio from 44:23 to 44:43)

Into this is the q matrix. So, what we will have is 1 minus 1 into half. So, I just have to put half here.

(No audio from 45:01 to 45:25)

So, this is the solution, the complete solution for this system actually it seems very painful sometimes. But, the point is that you can actually get it fairly, if you follow a

systematic procedure you can get the solution of this equation these, this dynamical system.

Now, just before you proceed let us just try out what we were discussing some time back. If I have got if you look at this particular solution let us not look at it just as a mathematical quantity just look what it says. It says that your solution is a you are going to have two components to this solution this and this. The first this is an unstable system incidentally because, it if there is any non zero initial condition you will find that there are terms which will grow with time, this is growing with time, this is positive. So, it will grow with time.

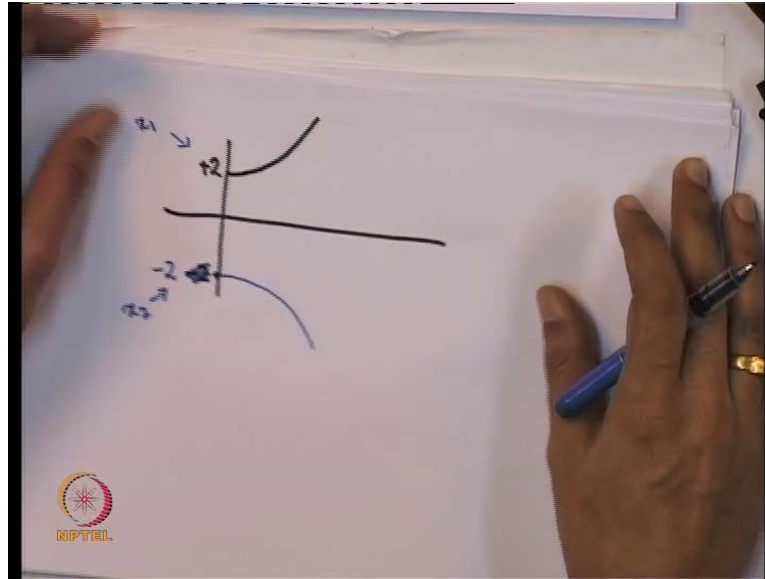

If you look at this 1 and minus 1 into this you will find that certain sets of initial conditions can be made to selectively excite certain modes. For example, if I chose my, (No audio from 46:39 to 46:47) in that case you will find at in fact, it is practically proportional to this particular transpose of this row vector. In that case the product of this is non zero will get the answer to be two this if you look at this product it will turn out to be 2. This particular product will turn out to be 0.

So, if I have got this set of initial conditions I will end up exciting only this mode. Similarly, if you have got a set of initial conditions two. You will end up exciting this mode, but, not excite this mode.

So, this is the important point, the second point which you will notice is given the fact that. Suppose, this mode is excited in that case if you look at for this mode there is certain pattern to how much of the mode is visible in x_1 and x_2 . So, if x_1 is a positive quantity x_2 becomes a negative quantity if only this, if you look at only this mode. So, this particular mode has got this characteristic. If it is excited the component corresponding to that mode the observability, you know the amount or the nature of the mode in x_1 and x_2 is a bit difference in the sense that if it is plus 1 here it is minus 1 here.

So, if only the if you give these initial conditions. For example so, that only this mode is excited your response is going to look like this.

(Refer Slide Time: 48:33)

So, you start from plus 2. So, I will give it two different colors may be I will call this is minus 2 this is x_2 , this is x_1 , you will find that this will grow like this whereas, this grow like this.

So, the characteristic here if you look is exactly you know if only this mode is excited x_1 and x_2 always appear in this ratio 1 is to minus 1. Of course, if you have got both modes excited then of course, it is you cannot say that x_1 and x_2 are going to be in a ratio of 1 and minus 1 etcetera. Then it is going to be a combination though you will have to actually evaluate this response and you cannot say that in general. But, if you look at this mode only and assume that only this mode is excited then x_1 and x_2 and this ration.

(Refer Slide Time: 49:48)

ISSUES

$$A = \begin{bmatrix} 0 & 1 \\ 0 & 1 \end{bmatrix} \rightarrow \text{eigenvalues?}$$
$$\det(A - \lambda I) = (1 - \lambda)^2 = 0$$
$$\lambda_1 = 1, \lambda_2 = 1$$

So, that is the significance of the Eigen vector. Now, one small point which we will try to conclude this particular lecture look at this particular system. This particular system has got 1 1 0 and 1 the Eigen values of this are easy to find out. If you do A minus λI you will get. So, that now, the problem is that if you have got both the Eigen values here in this particular case 1 and 1 it turns out this particular matrix cannot be diagonalised. So, this is one problem which we are going to face.

So, remember that whatever I have talked the general response of a linear system in terms of mode justified. It is the continent of the fact that the system can be diagonalised there are systems which cannot be diagonalised so, this one of them. So, if you look at this particular system the response of it is not going to be of the form which I told you.

(Refer Slide Time: 50:54)

$$\begin{aligned}\dot{x}_1(t) &= x_1(t) + x_2(t) \\ \dot{x}_2(t) &= x_2(t) \\ x_2(t) &= e^{\lambda t} x_2(0) \\ \dot{x}_1(t) &= \underbrace{x_1(t)}_{ax} + \underbrace{e^t x_2(0)}_{bu}.\end{aligned}$$

For example, look at this. So, I am just rewriting this system (No audio from 50:58 to 51:05) this is what this particular if you have got \dot{x} is equal to Ax with A as this effectively your dynamical system is this. It is a coupled dynamical system.

So, your x_2 I am sorry, this should be \dot{x}_2 should be will be equal to e raise to λ , λ is 1 . So, this is 1 into t x_2 of 0 and x_1 from this equation you will get. So, from this equation you get this from this equation you are getting this. (No audio from 51:47 to 51:54) So, this you can treat as ax and this as bu , this is just u .

(Refer Slide Time: 52:10)

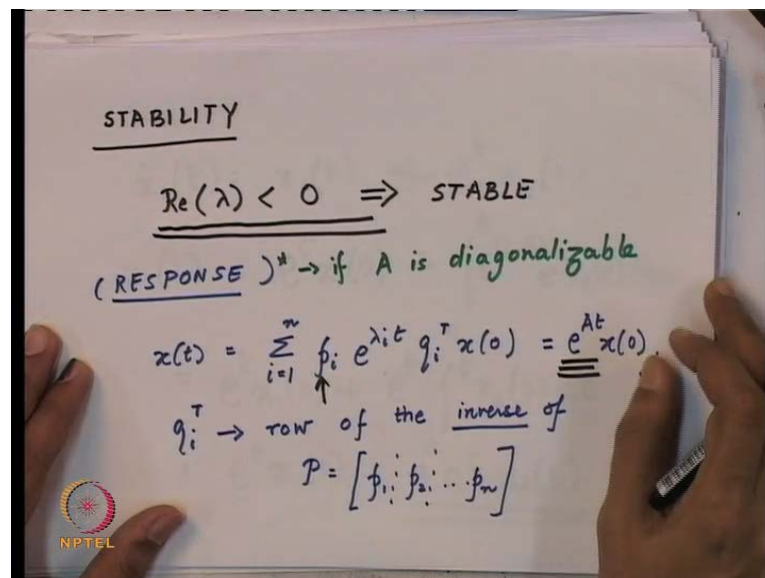

$$\begin{aligned}\dot{x}_1(t) &= x_1(t) + e^t x_2(0) \\ x_1(t) &= e^t x_1(0) + \int_0^t e^{(t-\tau)} e^{\tau} x_2(0) d\tau \\ &= e^t x_1(0) + e^t \int_0^t x_2(0) d\tau \\ &= e^t x_1(0) + \underline{\underline{t e^t x_2(0)}}.\end{aligned}$$

So, what you will get is $x(1) = t$ is equal to x , I will just rewrite this, plus e raised to $2t$ times 2 of 0 . So, what is the solution of this you have done this before a is equal to 1 here. So, you will get e raised to t times 1 of 0 plus 0 to t e raised to t minus τ into b u .

So, b u is nothing, but, this so, you will get e raised to u of τ is nothing, but, e raised to τ times 2 of 0 d τ . So, you will get e raised to t times 1 0 plus e raised to t 0 to t times 2 of 0 d τ . So, you will get e raised to t times 1 0 plus if you evaluate this you will get t e raised to t times 2 of 0 . So, the response earlier you are getting just e raised to something terms, if your matrix is not diagonalizable you start getting terms of this kind in the response.

So, this is one example in which you cannot diagonalise this system the Eigen values are equal and in fact, you will not be able to get p_1 and p_2 , which are linearly independent if p_1 and p_2 are linearly independent P cannot be inverted.

(Refer Slide Time: 53:53)

So, that is why you cannot get a response in the form you want. So, let us conclude this particular lecture by just looking at what we have learnt, the response of a linear system $\dot{x} = Ax$ is equal to $x(t) = e^{At} x(0)$. If A is diagonalizable is given by $x(t) = \sum_{i=1}^n p_i e^{\lambda_i t} q_i^T x(0)$, the summation this is the general response for a n th order system.

Summation of this term where p_i are the Eigen values corresponding to p_i is the Eigen value, Eigen vector corresponding to the i th Eigen value λ_i is the i th Eigen

vector, i th Eigen value λ_i is nothing, but, the row of the inverse of the right Eigen vector matrix this is often written in the form $e^{\lambda_i t}$ of x .

So, this particular if you come across this somewhere in the text book this is what it really mean you have to expand it in this form. Stability of this system can be just got by looking at the real part of the Eigen value of λ . So, this is basically what we see, this we have seen some very simple examples in this particular class second order example what we will do in the next class. We will do a few numerical examples we did one today, we will do a few more in which λ for example, are complex in that case what response does one expect. And then we will go on to analyzing some systems and bring out some general modeling principles.

So, this is what we will do in the next few lectures. So, once we do this of course, we will go onto numerical integration and then we will study a bit about modeling. So, although you may get a bit lost in all this mathematical manipulations just stay on and we will come onto some real nice pal system examples as well.
