**Exercise No 21**  
**Algebraic Topological Method (ATM-III)**

We are now going to look into interesting problems that he also saw in the case of finite element method but you are going to use algebraic topological method solve this problem and in the case of finite element method we have done the problem using a 2D approximation we have not done a 3D problem we have done a 2D problem the case of algebraic topology have to go to a 3D problem because we need certain parameters 3D nature I will explain this as we go but now let's look into the problem itself see how this problem is structured sun and how this problem is going to be replicated using Matlab program that we are going to plan  
(Refer Slide Time: 01: 00)

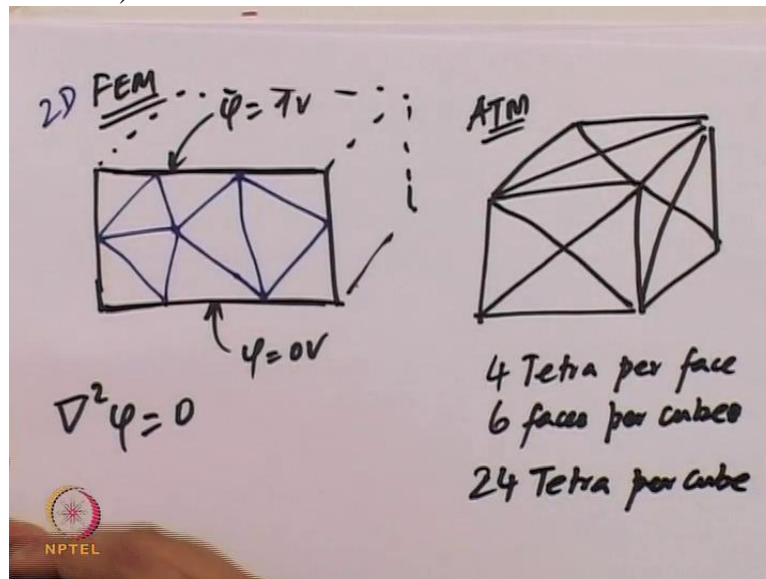

so let's start with the problem so we had this parallel plate capacitor which was in the case of the finite element method basically a 2D approximation and you said that of potential is 1 volte and the bottom potential is going to be zero volt so for us

to this problem in the case of algebraic topology so this is the FEM problem that we saw but in order to do it in the algebraic topological method we need to go to the 3rd dimension the third dimension is let's say this is done in this manner when we are kind of closely discretizing this grid so let's say this is our problem in the case of 2D FEM so this is a 2D problem and in the case of ATM as I said the essential I need to go to the i second dimension because parameters and this parameter will be so if this is a for you to compare this was definitely long but you only took the part of a cross section and we solved it in a FEM

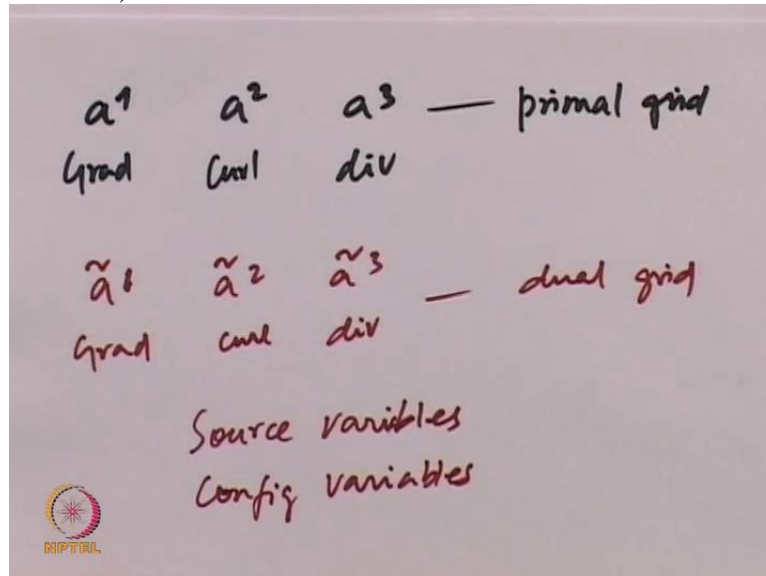

method so this was basically Laplace Equation that we solved these are the boundary condition that we have enforced.

(Refer Slide Time: 02: 47)

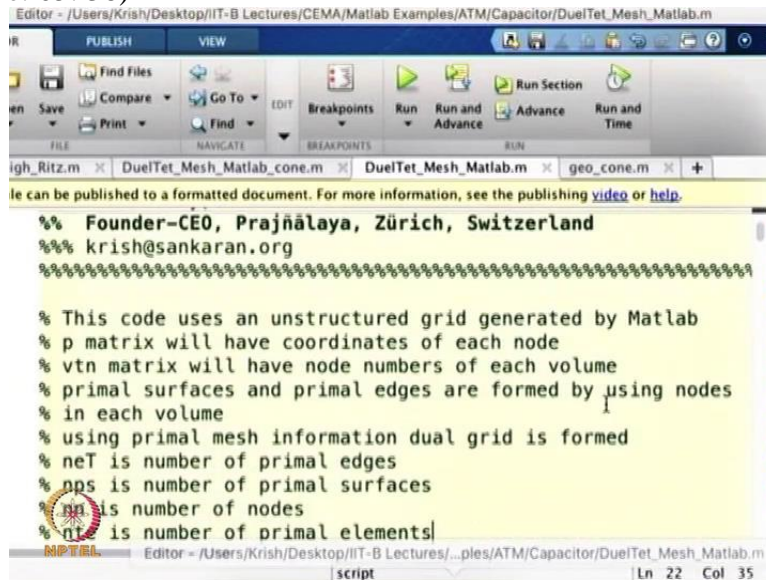

The case of algebraic topological method our discretisation is going to be tetrahedral. So each phase will have certain number of tetrahedral and you can basically see triangle is a side of a tetrahedral so you can imagine there will be 4 triangles per face and there are totally going to be 1,2,3,4,5,6. So there are going to be 4 tetrahedral per face and there are totally 6 faces for cube so we are going to have totally 24 Tetrahedron there is going to be a larger number of elements in the case of the algebraic topological method our elements are the 3D elements they are the tetrahedral we cannot solve the problem only using 2D approximation like the way we did finite element but we need to go to the 3rd dimension and the reason will be obvious when we go into the program itself so remember algebraic topological we set certain parameters

(Refer Slide Time: 04: 23)

And those parameters are going to be the  $a_1$   $a_2$   $a_3$  these are all in the primal grid the gradient  $a_2$  will be the curl  $a_3$  will be the divergence these are all in the Primal grade and we will have also the dual grade  $\tilde{a}_1$   $\tilde{a}_2$   $\tilde{a}_3$  and these are the gradient and divergence in the dual grade and what we have done here is we have set two grids when to have types of variables one will be the source variable another will be the configuration variables and the source variable will be on 1 grid send the configuration variables are going to be on the other grid

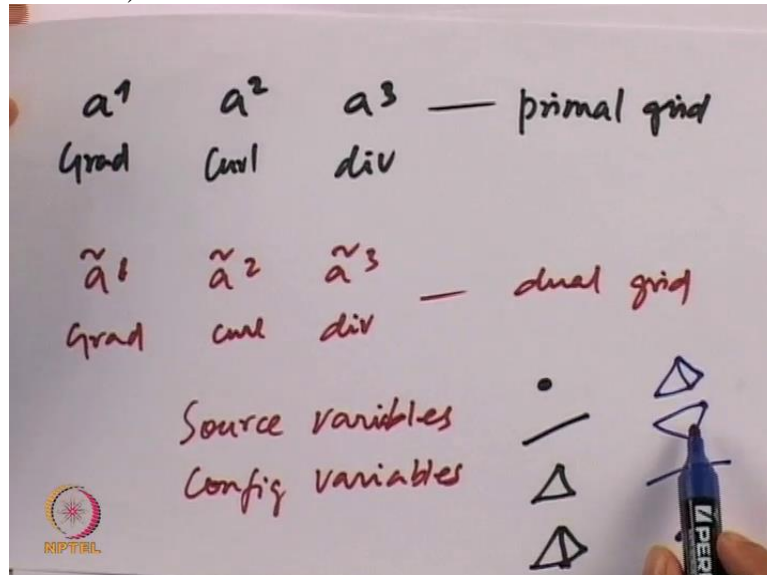

(Refer Slide Time: 05: 38)

So let's look into the code itself and try to understand how this code is structured in order for you to get a good appreciation of algebraic topological method and we are solving this for a simple problem of parallel plate capacitor so this code is using unstructured grid and we are generating it directly using Matlab you are not going to use any specific solvers for that and

what we are getting what is the Primal surface Primal age and all these kind of things and we are using the Primal match information to generate the dual grid information. So the dual grids are going to be the grades that are going to help us to associate certain parameters where as the Primal grid will be for other kind of parameters and those parameters as I said will be either shows variable or configuration variable.

(Refer Slide Time: 06 : 40)

So let's look into the structure of three dimensional problem we have the points we have the lines we have the faces and we have the Tetra the dual grade of the point is going to be the dual volume which is going to be tetra or any other volume so in this case let's say for the sake of simplicity we call this as a Tetra but this could be of any shape any size or any form so it will be a n hedron of the line will be a surface the dual of a surface will be a line the dual of the volume will be a point So the number of lines.

(Refer Slide Time: 07: 39)

Primal	Dual
$n$ -nodes	$n$ - $\tilde{v}$ olumes
$e$ -edges	$e$ - $\tilde{s}$ urfaces
$s$ -Surfaces	$s$ - $\tilde{e}$ ges
$t$ -volumes	$t$ - $\tilde{n}$ odes

so if you say we are going to have  $n$  number of nodes  $e$  number of edges and  $s$  number of surfaces and  $t$  number of tetras in the Primal case the dual case will be number of volumes will be also equal to  $n$  number of volumes dual volumes. so I put tilde on the top of it we will have a number of dual surfaces and we will have as number of dual edges. And we will have  $t$  number of dual nodes. So this is the number of nodes, number of edges, number of surfaces, number of volume  $s$  .so this is the primal and this is the dual.

(Refer Slide Time: 09: 40)

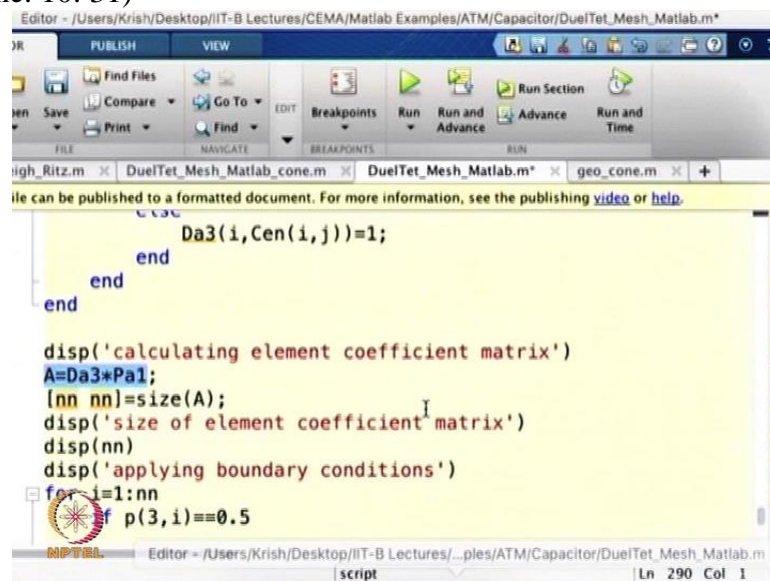

Primal	Dual
$n$ -nodes	$n$ - $\tilde{v}$ olumes
$e$ -edges	$e$ - $\tilde{s}$ urfaces
$s$ -Surfaces	$s$ - $\tilde{e}$ ges
$t$ -volumes	$t$ - $\tilde{n}$ odes
Conf. Variable	Source variables
$\psi$ = elect pot.	$\vec{D}$ = electric excitation

So what we are going to have as the dual grid is going to be the place where we are going to keep the source variables and the primal great is going to be the place where we are going to keep the configuration variables in this case the potential will be in the Primal grade where as they will be in the dual grade  $B$  is the electric excitation and  $v$  is the electric potential. You also called as electric displacement so the dual grade is going to be the place where we will

have the source variables and the configuration variables are in the Primal grade so in our case we will be working only with the configuration variable and source variable in the form that we have described here switching them will not give you the right results so you have to be careful that you don't mix between source variable and configuration variable and we have discussed the way to define source variable and configuration variable during the lecture so for people who have missed it please go back to the lecture module on the algebraic topology and get a sense of what we are doing here so let's go to the code

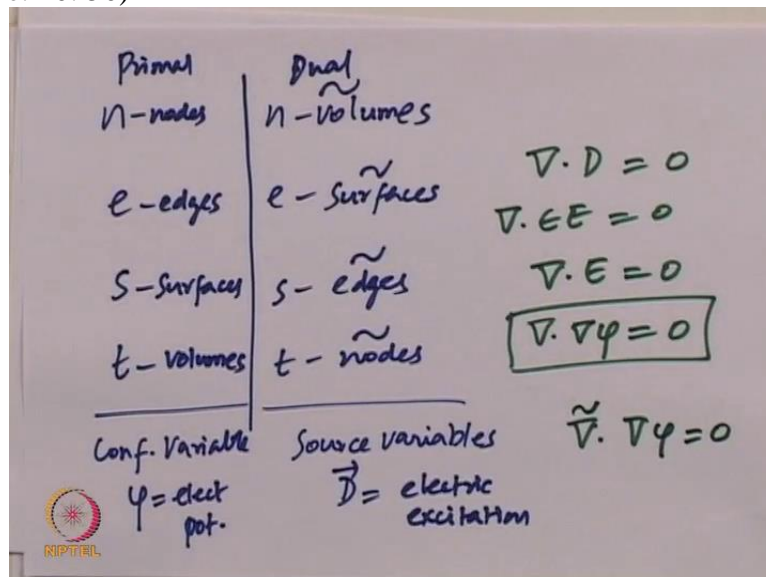

(Refer Slide Time: 10: 31)

```

```

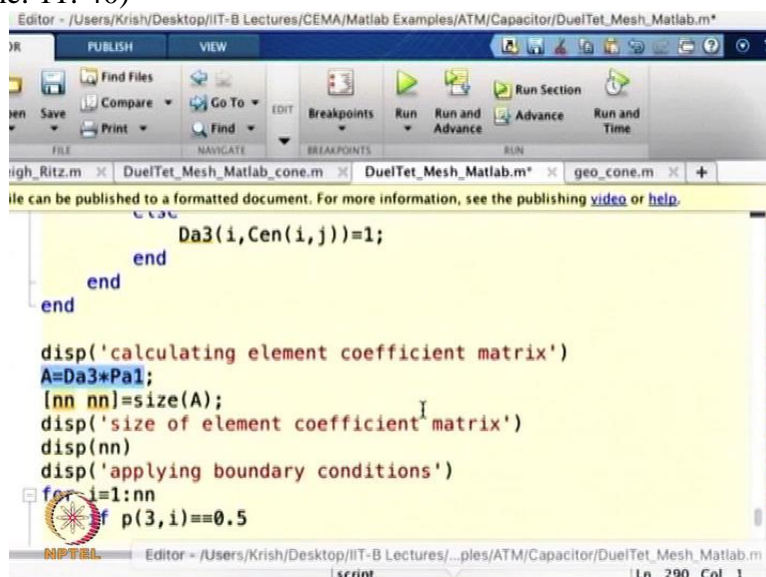

So the code is going to be a simple program for computing the value of the potential in a parallel plate capacitor I said simple because if you followed the logic of algebraic topology you will understand how you are solving the problem.

(Refer Slide Time: 10: 50)

So basically what you are solving for this the divergence of  $b$  is equal to zero. But we are going to make this equation look in a different way what you are going to do is we keep the divergence out and remember the divergence of the is in the source variable so we are going to have a dual grid and what we are going to write  $D$  as we are going to write it as Epsilon  $E$  is equal to zero so we assume that he is positive difference so we will have divergence of equal to zero and we know that he is itself a gradient of  $\Phi$ . So we have starting problem so we can write it has minus gradient of  $\Phi$  and a minus sign will go away and we will have this equation.

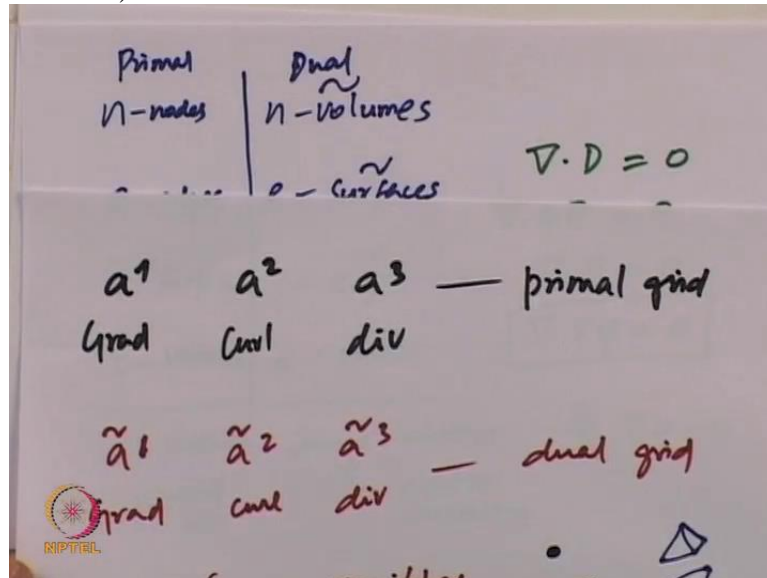

(Refer Slide Time: 11: 40)

So let's look at the code what we have done here is we have got a variable as  $a$  so basically this is a variable that we are talking about so this is the divergence dot the gradient so this is operator what we are looking at the operator has two components the one is acting on  $\phi$  and

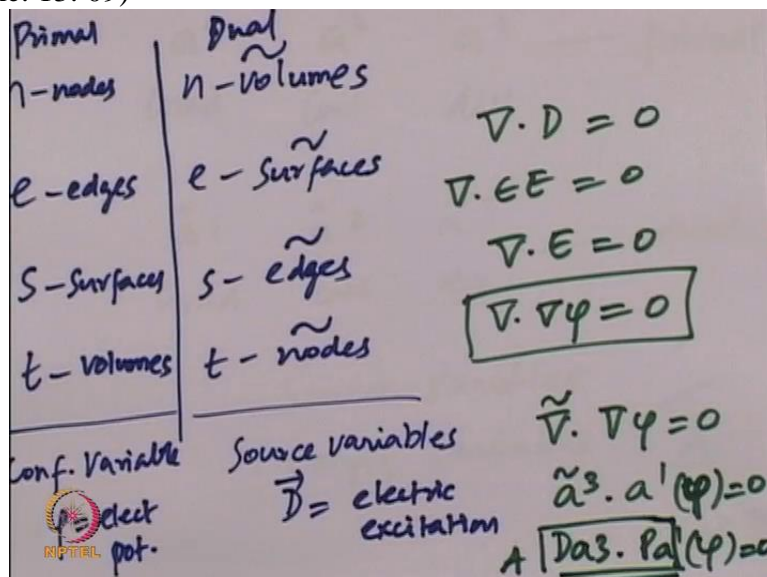

she is on the Primal grade so it will be written with Rho tilde where is the one that is operating on D which is this entire time is going to be on the source variable and it's going to be on the dual grid so we have a tilde. And this is fee is equal to zero what we are going to see is we know that the gradient curl and divergence in the Primal grade and dual grade will have the form A1 A2 and A3 as follows.

(Refer Slide Time: 12: 40)

So we can write this particular equation using this logic what we have got so let me put it this way so you can see it below. We are going to substitute the value of divergence and gradient using a A1 A2 and A3 show the value for divergence in the dual grid is A3 tilde.

(Refer Slide Time: 13: 09)

So I am going to put a 3 tilde and the value for the Primal gradient is going to be a one so I am going to put a 1 equal to Phi. So Phi equal to 0. And of course in the coding of the program what we have returned as is this is the dual a3 so we have put it as Da 3 dot this is

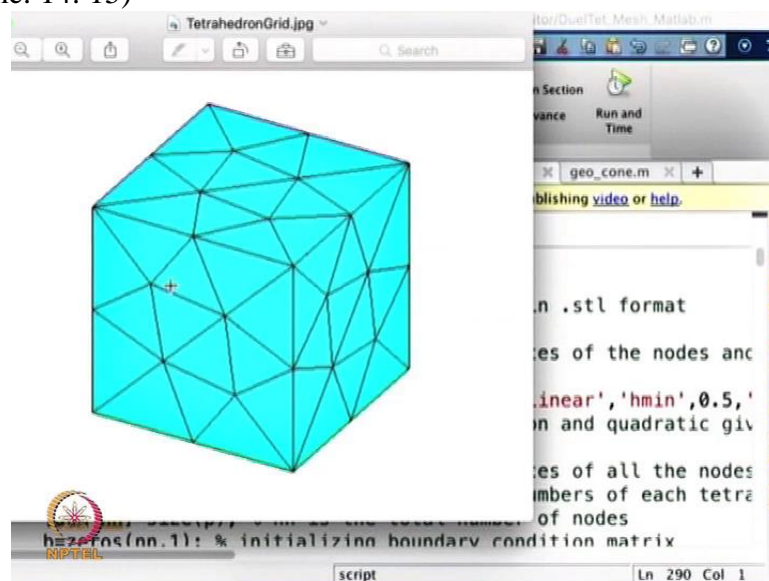

primal a1 so  $\Phi_1$  multiplied by the  $\Phi$  is equal to zero. So this value is a value that we are calling as  $a$  and this is an operator and this operator is operating on  $\Phi$  to get the value that we are interested in and let's go into the code itself my one and see how you are getting there. (Refer Slide Time: 14: 03)

```

%% generating primal mesh
model = createpde(1);
% importing model of the meshlab software in .stl format
importGeometry(model,'MeshLab.stl');
% generating mesh data in terms of coordinates of the nodes and
% connected to each element
Mesh=generateMesh(model,'GeometricOrder','linear','hmin',0.5,'
% here, linear gives 4 nodes per tetrahedron and quadratic giv
% per tetrahedron
p=Mesh.Nodes; % p matrix contains coordinates of all the nodes
vtn=Mesh.Elements; % vtn stores the node numbers of each tetra
[dim nn]=size(p); % nn is the total number of nodes
h=zeros(nn,1); % initializing boundary condition matrix
script Ln 290 Col 1

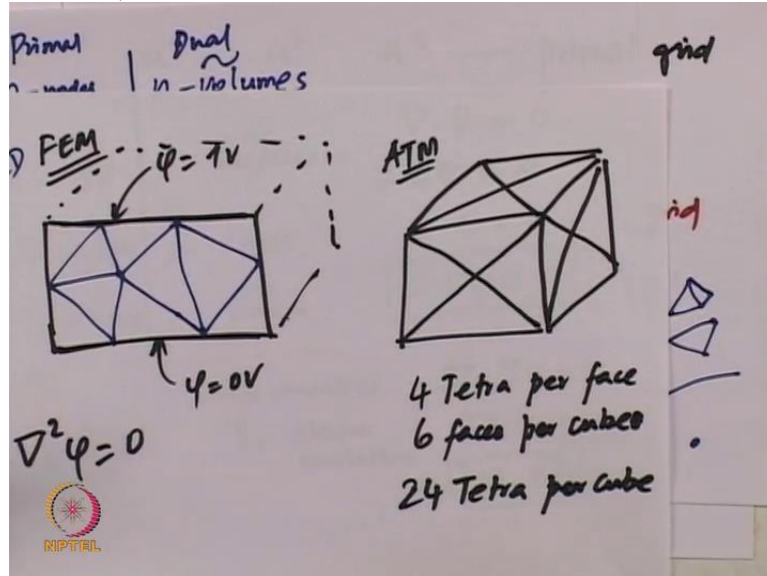

```

So we are generating the Primal grid using and in build program create PDE. (Refer Slide Time: 14: 15)

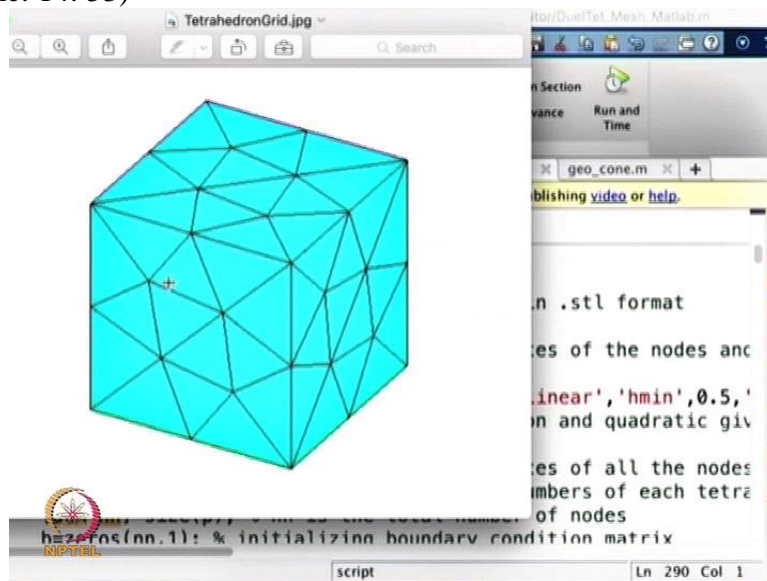

And we are getting the model and the model itself looks in this form it's a parallel plate capacitor but we are having a three-dimensional KCR so this is a top surface of the top conductor there is a bottom conductor and his other sides and as you can see they are going to be tetrahedral everywhere in our case before I explained it in a simplified manner in a paper where you see that is  $Q$  will have several number of tetrahedral.

(Refer Slide Time: 14: 45)

You have unstructured tetrahedral when the tetrahedral structure then you will have certain cemetery like in the case we have shown here.

(Refer Slide Time: 14: 53)

Where is in the case of an unstructured grid you cannot predict number of tetrahedral their they are going to sit on one side of the cube and we have a very very fine discretisation so there are more tetrahedral sitting than a simple case what we have shown.

(Refer Slide Time: 15: 10)

And this is the problem geometry that we are going to use for our simulation.

(Refer Slide Time: 15: 14)

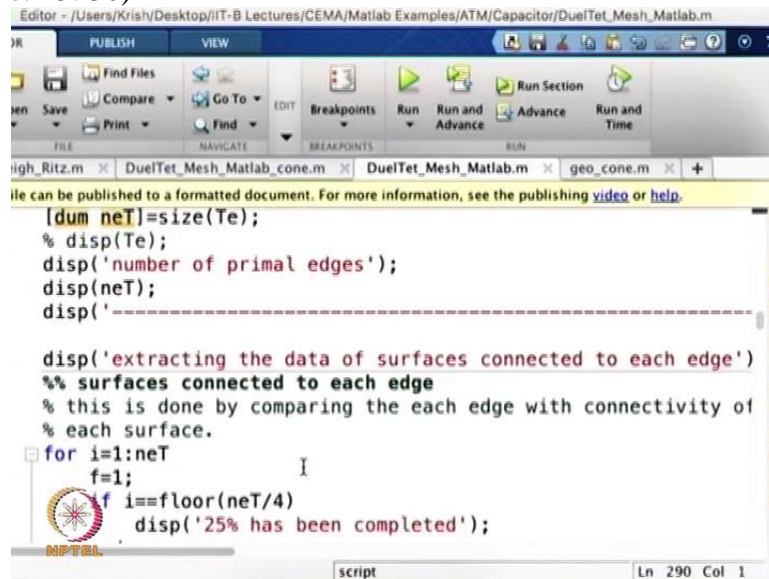

```

And you are solving the simultaneous equations initially we had we call to be where B is a boundary condition and we are able to solve for this equation by inverting the a and we are plotting the potential distribution for that problem so if you run this particular problem at the path what we will get is several information that we are interested.

(Refer Slide Time: 18: 26)

So there are two things one is grid itself that is being generated.

(Refer Slide Time: 18: 31)

So this is the great that we are going to generate is surface has 1 2 3 4 5 6 7 8 9 10 11 12 13 14 roughly 14 or 15 tetrahedral and we are able to get to the point of seeing the result where we are able to simulate the problem for the potential .

(Refer Slide Time: 19: 00)

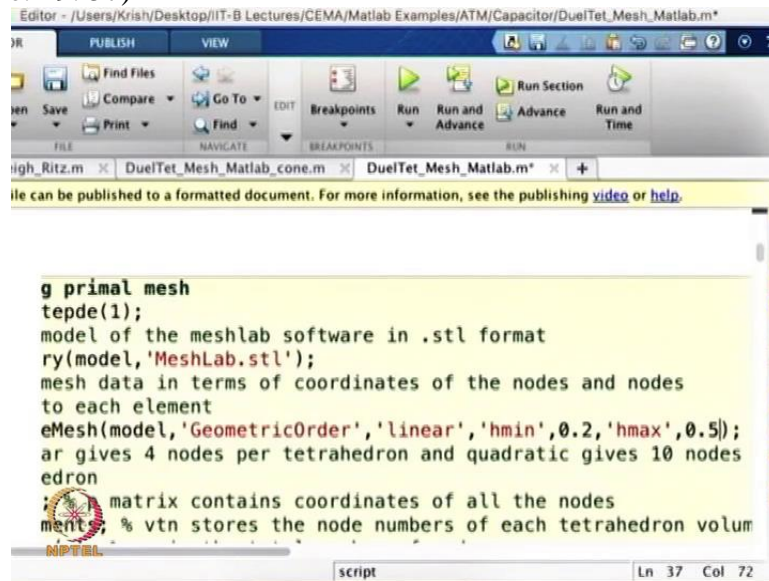

and what you see is the potential this is a three dimensional problem and you will see it is still not a very smooth line the way we want it ideal it should be parallel lines you don't see the parallel lines because the disc utilisation is very coarse we see that there are some errors this can be improved if we go into a very very fine discretisation and get a better result based on that.

(Refer Slide Time: 19: 30)

So that's now get back to the code and reduce the discretisation a bit so as to generate smaller tetrahedral so that our accuracy can be improved the way to do that is in the code we have to set the value for h which is a parameter that we are going to reduce so let's go back to the code.

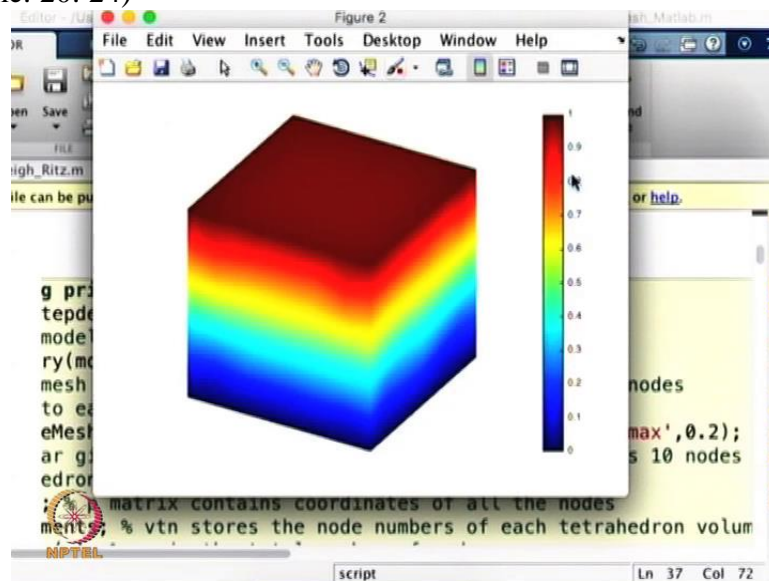

(Refer Slide Time: 19: 57)

```
g primal mesh
tepede(1);
model of the meshlab software in .stl format
ry(model,'MeshLab.stl');
mesh data in terms of coordinates of the nodes and nodes
to each element
eMesh(model,'GeometricOrder','linear','hmin',0.2,'hmax',0.5);
ar gives 4 nodes per tetrahedron and quadratic gives 10 nodes
edron
; matrix contains coordinates of all the nodes
ments; % vtn stores the node numbers of each tetrahedron volum
```

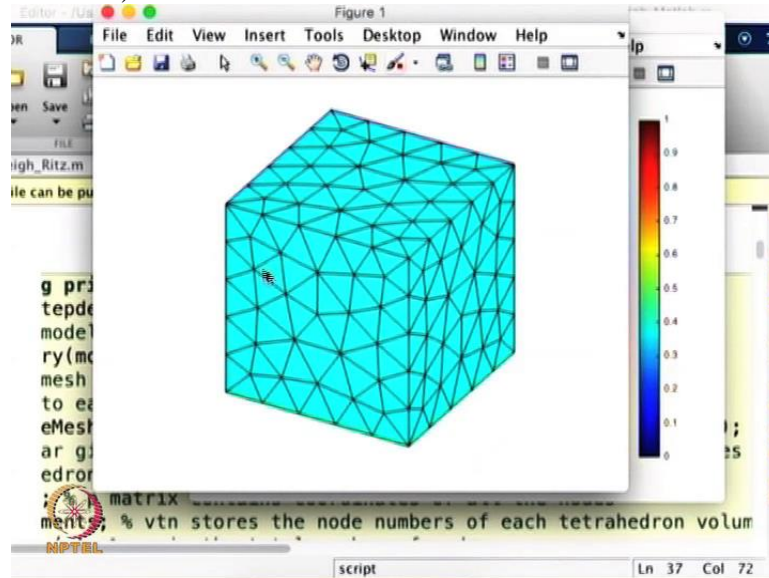

So now we can reduce the discretisation by changing this value here which is the h min value so if you said that its min value to be 0.5 we got the discretisation which we got now so let's reduce it to 0.2 and as Max is also 0.2.

(Refer Slide Time: 20: 24)

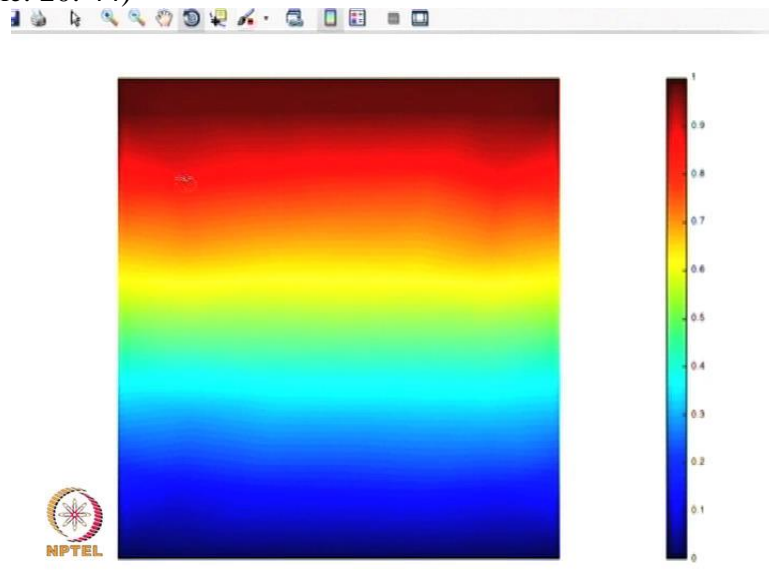

So if you are discretizing this particular problem in the way what we have done now.

(Refer Slide Time: 20: 29)

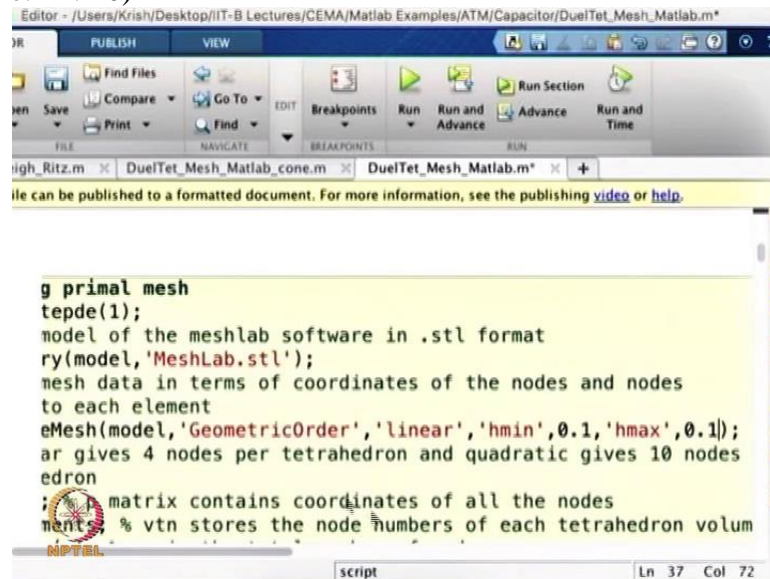

We have reduced the mesh maximum and minimum edge length what we see here is the result.

(Refer Slide Time: 20: 44)

And you can compare that with the earlier result the result are much more finer and you see that you still see certain changes in the equipotential line the reason for this is the grid is still not fine this will change if we go even finer and we can do that by changing the value of  $h$  in the main code.

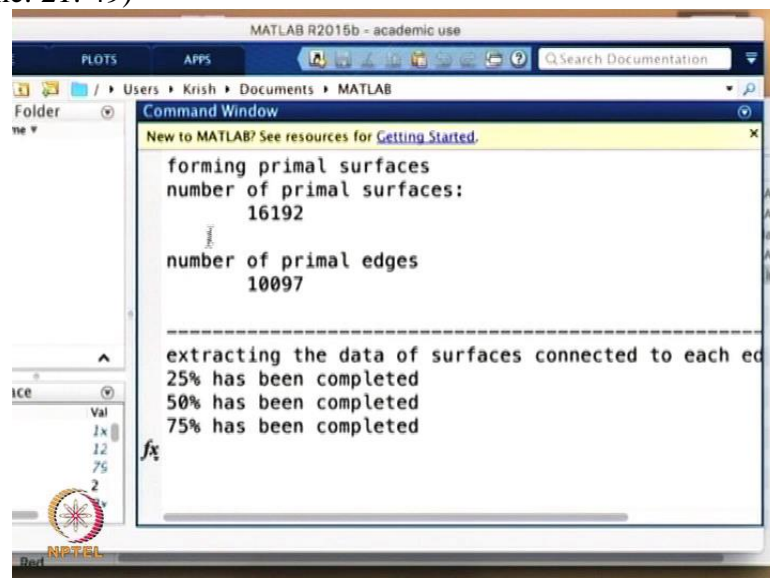

(Refer Slide Time: 21: 10)

```
g primal mesh
tepde(1);
model of the meshlab software in .stl format
ry(model,'MeshLab.stl');
mesh data in terms of coordinates of the nodes and nodes
to each element
eMesh(model,'GeometricOrder','linear','hmin',0.1,'hmax',0.1);
ar gives 4 nodes per tetrahedron and quadratic gives 10 nodes
edron
; matrix contains coordinates of all the nodes
ments: % vtn stores the node numbers of each tetrahedron volum
```

So now we are going to reduce the  $h_{min}$  and  $h_{Max}$  even find her so as to see what is the impact of discretization on our problem resolution so discretizing it final is going to take us a long time to run the code just to see the proof of concept that we are converging and doing this so you have to make define choice of of what is going to be your discretisation for 0.1 we are already in a very very fine discretisation so I am going to run it.

(Refer Slide Time: 21: 49)

```
forming primal surfaces
number of primal surfaces:
    16192

number of primal edges
    10097

-----
extracting the data of surfaces connected to each ed
25% has been completed
50% has been completed
75% has been completed
```

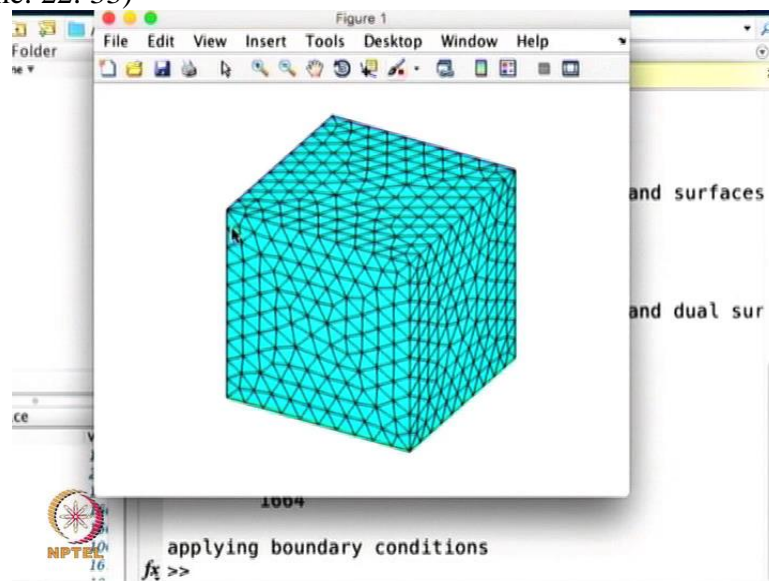

So you will see in the main window that we have 16192 surface 10097 Primal edges and we are extracting the data for the Primal surfaces edges and volumes and with that we will go and do the something for the dual edges dual volumes and dual surfaces and we are extracting the value and we are seeing the result.

(Refer Slide Time: 22: 19)

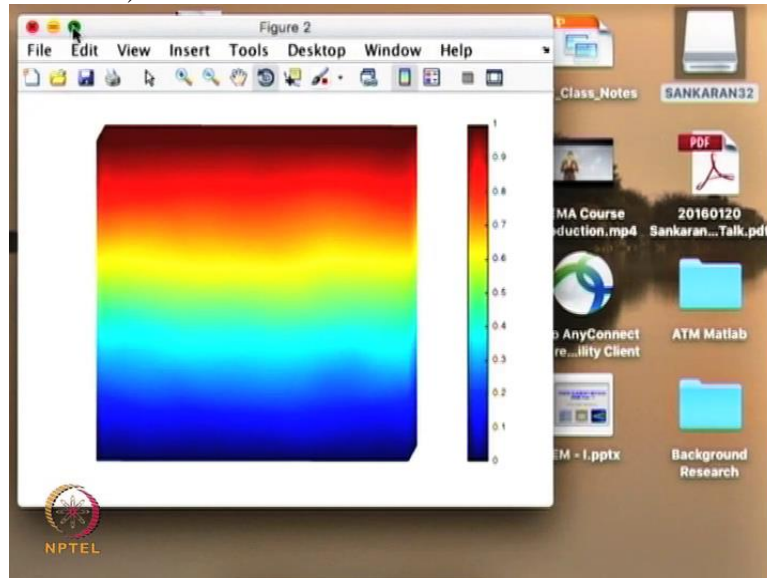

So what you see are two results the first one is the result for the potential itself so before that maybe it's worth to go and see the problem discretisation itself.

(Refer Slide Time: 22: 33)

This is a very fine discretisation and as you can see we have gone from the initial problem of 0.5 as the minimum and maximum discretisation we have now 0.1 as the cell size the maximum size of the tetrahedral edges is going to be 0.1 and for this point discretisation we are able to get result which is also much more refined and this week and see in the result of the potential itself what you have computed.

(Refer Slide Time: 23: 30)

You can see that the potential lines are much more finer than before. The equipotential lines are much more refined than before and the way we have computed the dual grade and the Primal grade is very characteristic to the way a normal problem is solved in the case of algebraic topology so what I wanted to do is I wanted to use his opportunity also to do the same problem that we have also so in the case of finite element method the conical capacitor so we are going to do the same problem that we saw before in the finite element method which is a conical capacitor and we are going to run the same problem using algebraic topology and see the result this we will do in the next module we will come back and simulate the problem using algebraic topological method thank you.
