Indian Institute of Technology Bombay.

Week-7.

Lecture-17.1.

Variance from a slightly different perspective.

(Refer Slide Time: 0:17)

Foundations of Wavelets, Filter Banks & Time Frequency Analysis

Last time we learnt:

- Worked out an example of the Haar wavelet and obtained its time(frequency) center, time(frequency) variance.
- We saw that variance in frequency domain is *infinity* due to the side lobes

Today we will learn:

- A new definition for variance and its relation to the energy in $\frac{d\phi}{dt}$.
- Explain why the variance in frequency domain diverges for Haar wavelets using the new definition.

Prof. Vikram M. Gadre, Department of Electrical Engineering, IIT Bombay

Now all this while in our discussion when we talked about time and frequency together and so on in the previous lecture, we have been worried about the side lobes as we call them. We said, well it is all right to look at the main lobe and talk about presence in the main lobe but

then we have these side lobes and the side lobes are falling off only by the factor $1/\omega$ in magnitude. And as you can see the side lobes have created a problem.

After multiplication by ω^2 in the calculation of variance, the side lobes create a periodic function to be integrated, a periodic nonnegative function and we are in trouble. So this tells us again why we have to go much beyond the Haar. We have been asking again and again why we cannot be content with the Haar multiresolution analysis, now we have one more formal answer. If we look at the scaling function for the Haar multiresolution analysis, its variance in frequency domain is infinite.

It is not at all confined in the frequency domain in this sense. Now, it is a natural question to ask what is it that made this variance infinite. Why did we have a divergent variance here? In fact, we can answer that question if we only care to make a slight adjustment of the expression for variance. the variance of $\hat{\phi}$ is finally as you can see given by $\int_{-\infty}^{\infty} \omega^2 |\hat{\phi}(\omega)|^2 d\omega / \|\hat{\phi}\|_2^2$.

(Refer Slide Time: 2:55)

$$= \int_{-\infty}^{+\infty} \frac{\omega^2 |\hat{\phi}(\omega)|^2 d\omega}{\|\hat{\phi}\|_2^2}$$

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP IIT BOMBAY

$$= \frac{1}{\|\hat{\phi}\|_2^2} \int_{-\infty}^{+\infty} |j\omega \hat{\phi}(\omega)|^2 d\omega$$

Fourier transform of $\frac{d\phi(t)}{dt}$

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP IIT BOMBAY

$$= \frac{2\pi (\text{energy in derivative})}{2\pi (\text{energy in function})}$$

And this can be written as ω^2 times $|\hat{\phi}(\omega)|^2$ divided by the norm of $\hat{\phi}$ in L^2 squared. Now this norm is a number, it can be brought out of the integral. So I can rewrite this as $\frac{1}{\|\hat{\phi}\|_2^2} \int_{-\infty}^{+\infty} |j\omega \hat{\phi}(\omega)|^2 d\omega$. I will also do a little bit of rearrangement in the integral. I will write the integral as $\int_{-\infty}^{+\infty} \omega^2 |\hat{\phi}(\omega)|^2 d\omega$.

Notice that if I take the modulus of $j\omega \hat{\phi}(\omega)$, it is essentially modulus ω^2 times modulus $|\hat{\phi}(\omega)|^2$. And modulus ω^2 and ω^2 are the same for ω real. But then when we write it like this, this has a meaning. It is essentially the Fourier transform of $\frac{d\phi(t)}{dt}$, Fourier transform of the derivative of ϕ . So essentially what we are saying is this variant is actually the energy in the derivative.

Of course remember you would have a factor of 2π there because this is the energy in the derivative but for a factor of 2π . So this would be 2π times the energy in the derivative divided by 2π times the energy in the function. And please note that this inference that we have made is independent of what function we consider. As long as the function is real, the variance in frequency is going to be this ratio, the energy in the derivative divided by the energy in the function.

(Refer Slide Time: 5:44)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP

For real $x(t)$,
 Ω -variance, σ_x^2
 $= \frac{\text{energy in } dx/dt}{\text{energy in } x}$

NIPTEL

Let us make that remark, for real functions, for real $x(t)$ the frequency variance, omega variance or σ_x^2 is essentially energy in dx/dt divided by the energy in x or the L^2 norm square and of the derivative of x divided by the L^2 norm of x . And now we have the answer why we ran into a problem for $\phi(t)$. As you can see $\phi(t)$ is discontinuous. So when its derivative is considered, there are impulses in the derivative and impulse is not square integrable and therefore the numerator of this quantity diverges, if you look at it from that perspective.

The moment we have a good discontinuous function, we have an infinite frequency variance and there we are. With this note then we realise that if we want to get some meaningful uncertainty, some meaningful bound, we might at least consider continuous functions and we shall proceed to relearn this concept further in the next lecture. Thank you.
