Lecture No 12
MVUE through Sufficient Statistics II

Hello Students, welcome to lecture 12 MVUE through sufficient statistics II.

(Refer Slide Time: 00:42)

Recall that

- ❖ A statistic $T(\mathbf{x}) = T(X_1, X_2, \dots, X_N)$ of θ is called sufficient if $f(x_1, x_2, \dots, x_N; \theta | T=t)$ or $p(x_1, x_2, \dots, x_N; \theta | T=t)$ does not involve θ
- ❖ Factorization theorem- $T(\mathbf{x})$ is sufficient if and only if
$$f(\mathbf{x}; \theta) = g(\theta, T(\mathbf{x}))h(\mathbf{x}) \text{ Continuous case}$$
$$p(\mathbf{x}; \theta) = g(\theta, T(\mathbf{x}))h(\mathbf{x}) \text{ Discrete case}$$
- ❖ Rao Blackwell theorem- Given an unbiased estimator $\hat{\theta}'$, and sufficient statistic $T(\mathbf{X})$, we can get an unbiased estimator $\hat{\theta} = E(\hat{\theta}' / T(\mathbf{X}))$ with $\text{var}(\hat{\theta}) \leq \text{var}(\hat{\theta}')$

I recall that, a statistics T_x that is a function of X_1, X_2 up to X_N is called sufficient, if the conditional PDF or conditional PMF does not involve θ . That is the definition of sufficient statistics and we discussed also Factorization theorem T_x is sufficient if and only if. The joint PDF is a function of θ can be factorized into two vectors. One vector g is function of θ and T_x , other vector is h that is a non-zero function of X_1, X_2 up to X_N only.

So the same can be written in the case of discrete case also in that case probability mass function as a function of θ is product of these two vectors. Rao Blackwell theorem- given an unbiased estimator θ this head and a sufficient statistic TX we can get an unbiased estimator θ head that is given by E of θ head given TX which is also unbiased and which has variance, less than the variance of θ this head. So that way we can get a better estimate or using the Rao Blackwell theorem.

(Refer Slide Time: 02:15)

Recall that...

❖ Complete statistic- Suppose $T(\mathbf{X})$ is a statistic such that $E(g(T(\mathbf{X}))) = 0$ for $\forall \theta$ for any bounded function $g(T(\mathbf{X}))$. Then $T(\mathbf{X})$ is a complete statistic iff $g(T(\mathbf{X})) = 0$ with probability 1.

In this lecture, we will look into some more properties completeness and see how a complete sufficient statistic can be used to find the MVUE.

We also discussed complete statistic suppose $T(\mathbf{X})$ is a statistic such that $E(g(T(\mathbf{X}))) = 0$, for all θ and for any bounded function $g(T(\mathbf{X}))$. Then $T(\mathbf{X})$ is complete if and only if $g(T(\mathbf{X})) = 0$ with probability 1. That means if this is equal to 0 expectation is equal to 0 then $g(T(\mathbf{X}))$ must be equal to 0 with probability 1, so that way we define complete statistics.

In this lecture we will look into some more properties of completeness and see how a complete sufficient statistic can be used to find the MVUE, minimum variance unbiased estimator.

(Refer Slide Time: 03:08)

Theorem

❖ If $T(\mathbf{X})$ is a complete statistic then there is only one function $g(T(\mathbf{X}))$ which is unbiased.

Proof

❖ Suppose there is another function $g_1(T(\mathbf{X}))$ which is unbiased.

$$\text{Then } E(g(T(\mathbf{X}))) = E(g_1(T(\mathbf{X})))$$

$$\therefore E(g(T(\mathbf{X}))) - E(g_1(T(\mathbf{X}))) = 0$$

$$\Rightarrow E(g(T(\mathbf{X})) - g_1(T(\mathbf{X}))) = 0$$

$$\Rightarrow g(T(\mathbf{X})) = g_1(T(\mathbf{X})) \text{ with probability 1}$$

We will start with a theorem, if $T(\mathbf{X})$ is a complete sufficient statistic then there is only one function $g(T(\mathbf{X}))$ which is unbiased. So given $T(\mathbf{X})$ there is only one function $g(T(\mathbf{X}))$ which is unbiased, so that is important. Now, if $T(\mathbf{X})$ is complete and unbiased, then we can find only

one function $g(T(X))$ which is unbiased. We will prove this theorem, suppose there is another function $g_1(T(X))$ which is unbiased.

So already $g(T(X))$ is unbiased, suppose there is another function $g_1(T(X))$ which is unbiased. Then E of $g(T(X))$ must be equal to E of $g_1(T(X))$, therefore if I take the E of $g_1(T(X))$ to the left hand side I will get E of $g(T(X))$ minus E of $g_1(T(X))$, that must be equal to 0 and we can take E outside E of $g(T(X))$ minus $g_1(T(X))$ must be equal to 0. Now $T(X)$ is a complete statistic therefore E of $g(T(X))$ minus $g_1(T(X))$ is equal to 0. Then this argument must be equal to 0 with probability 1.

So this will replace that $g(T(X))$ is equal to 0 and $T(X)$ with probability 1, therefore what do we conclude that $g(T(X))$ is a unique unbiased estimator. If $T(X)$ is a complete sufficient statistic there exists only one unbiased estimate that is $T(X)$.

(Refer Slide Time: 05:07)

Lehmann-Scheffe theorem

- ❖ Suppose $T(X)$ is complete sufficient statistic for θ and $g(T(X))$ is unbiased estimator based on $T(X)$. Then $g(T(X))$ is the MVUE

Proof:

- ❖ Suppose $\hat{\theta}(X)$ is any unbiased estimator of θ and $g(T(X)) = E(\hat{\theta}(X) | T(X))$ is another estimator.
- ❖ Using Rao Blackwell theorem, $g(T(X)) = E(\hat{\theta}(X) | T(X))$ is unbiased and $Var(g(T(X))) \leq Var(\hat{\theta}(X))$
- $g(T(X))$ is unique as $T(X)$ is a complete statistic and $\therefore g(T(X)) = E(\hat{\theta}(X) | T(X))$ is an MVUE

Now we will prove one classical theorem, which will help us to find out the MVUE. Suppose $T(X)$ is complete and sufficient statistic for θ and $g(T(X))$ is unbiased estimator based on $T(X)$. So we have an unbiased estimator based on $T(X)$, then $g(T(X))$ is the MVUE will prove this; suppose $\hat{\theta}(X)$ is any unbiased estimator of θ . Then $g(T(X)) = E(\hat{\theta}(X) | T(X))$ is another estimator.

And now using Rao Blackwell theorem, this estimator is unbiased and variance of $g(T(X))$ is less than equal to variance of $\hat{\theta}(X)$ but we know that $T(X)$ is a complete statistics

therefore there is only one function $g(TX)$ which is unbiased. Therefore $g(TX)$ is unique and its variance is less than the variance of any other estimator θ .

So therefore $g(TX)$ equal to $E(\theta)$ given TX is an MVUE, because it is unbiased and it is unique and its variance is less than equal to any other unbiased estimator therefore this will be the MVUE. So we saw that using the Lehmann Scheffe theorem, we can find out an unbiased estimator which has the minimum variance.

(Refer Slide Time: 06:57)

Example:
 Suppose $X_1, X_2, \dots, X_N$ are iid $B(1, \theta)$ random variables and

$$T(X) = \sum_{i=1}^N X_i$$

$T(X)$ is sufficient and complete.
 There is only one function of $T(X)$, which is unbiased.

$$\frac{1}{N} \sum_{i=1}^N X_i$$

is unbiased and it is an MVUE.
 Note that in this case we found the MVUE by inspection without explicitly determining $g(T(X)) = E(\hat{\theta}(X)/T(X))$

We shall consider one example; suppose X_1, X_2 up to X_N are iid independent and identically distributed Bernoulli θ random variables, this symbol represents the Bernoulli distribution with parameter θ , θ the probability of success. So $T(X) = \sum_{i=1}^N X_i$, i going from 1 to N , this is the statistic we are considering we have already proved that this statistic is sufficient and it is complete also.

So there is only one function of $T(X)$ which is unbiased, that is according to Lehmann Scheffe theorem. Now by inspection we get that if we divide this sum by N that is $1/N \sum_{i=1}^N X_i$ are going to N this will be unbiased, because you can take the expectation here and there will be N times expectation and then N , N will get cancelled. Therefore this is unbiased and I know that according to Lehmann Scheffe theorem there is only one unbiased estimator which is a function of the complete statistic.

Therefore this estimator must be an MVUE, so that we see how the completeness has helped us to find out the MVUE. Note that in this case we found the MUEVE by inspection without

explicitly determining $g(TX)$. So this is the formulation I want without this formulation we could find out this quantity but in all situation it may not be possible to find a complete sufficient statistic which is unbiased by inspection.

So we have to compute this statistic or this MVUE through this operation E of θ head dash given TX , so we have to perform this operation to find out the TX .

(Refer Slide Time: 09:17)

Exponential Family of Distribution

- ❖ A family of distribution with the probability density function of the form

$$f(x; \theta) = a(\theta)b(x)\exp(c(\theta)t(x))$$
 with $a(\theta) > 0$ and $c(\theta)$ as real functions of θ and $b(x) > 0$ is called an *exponential family of distribution*.
- ❖ Similarly a family of distributions

$$f(x; \theta) = a(\theta)b(x)\exp\left(\sum_{i=1}^k c_i(\theta)t_i(x)\right)$$
 with $a(\theta), b(x)$ and $c_i(\theta)$ as specified above, is called the *k-parameter exponential family*.
- ❖ An exponential family of discrete RV's will have the probability mass function in the above forms

We will discuss one important family of distribution for whose finding out a complete sufficient statistic is easier such a family is the exponential family of distribution, a family of distribution with the probability density function of the form $f(x; \theta)$ that is a function of θ and it can be written as a θ term is a θ another term is $b(x)$ and third term is exponential of $c(\theta)$ into $t(x)$.

So if we can write in this form with a θ greater than 0 because it is a probability this quantity we get a θ greater than 0 and $c(\theta)$ is a real function of θ and $b(x)$ greater than 0. Then this family will be called the exponential family of distribution with one parameter and now we can have a Multi parameter exponential family of distribution, so suppose $f(x; \theta)$ is equal to $a(\theta)$ into $b(x)$ into exponential of summation $c_i(\theta)$ into $t_i(x)$, i going from 1 to k .

Suppose in this form where as in here, $a(\theta)$ is greater than zero $b(x)$ is also greater than zero, non-negative function and $c_i(\theta)$ is also earlier function like this and then this family is known as the k parameter exponential family of distribution. We can find out an exponential

family of discrete random variables also in the similar manner if the probability mass function can be written in this form then that family will be called the exponential family of distribution.

(Refer Slide Time: 11:15)

Example

❖ Suppose $X \sim N(\mu, \sigma^2)$ then

$$\begin{aligned} f(x; \mu, \sigma^2) &= \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{1}{2\sigma^2}(x-\mu)^2\right) \\ &= \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{1}{2\sigma^2}(x^2 + \mu^2 - 2\mu x)\right) \\ &= \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{\mu^2}{2\sigma^2}\right) \exp\left(\frac{\mu}{\sigma^2}x - \frac{1}{2\sigma^2}x^2\right) \end{aligned}$$

❖ Thus $f(x; \mu, \sigma^2)$ belongs to a 2-parameter exponential family with

$$\boldsymbol{\theta} = \begin{bmatrix} \mu \\ \sigma^2 \end{bmatrix},$$

$$a(\boldsymbol{\theta}) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{\mu^2}{2\sigma^2}\right), \quad b(x) = 1,$$

$$c_1(\boldsymbol{\theta}) = \frac{\mu}{\sigma^2}, \quad c_2(\boldsymbol{\theta}) = -\frac{1}{2\sigma^2},$$

$$t_1(x) = x^2, \quad \text{and } t_2(x) = x$$

We will see one example; suppose X is the normal distribution with mean μ and variance σ^2 and μ and σ^2 are unknown, then the PDF we can write like this of x , μ , σ^2 it is a function of μ and σ^2 that is equal to $1/\sqrt{2\pi\sigma}$ into exponential minus $1/2\sigma^2$ into $x - \mu$ whole square.

So this we can write like that is $1/\sqrt{2\pi\sigma}$ into exponential minus $1/2\sigma^2$ into $x^2 + \mu^2 - 2\mu x$. Now this μ^2 term we can take outside, so that way it will be $1/\sqrt{2\pi\sigma}$ into exponential minus $\mu^2/2\sigma^2$ into exponential $\mu/\sigma^2 x - 1/2\sigma^2 x^2$ this part, minus because of this minus sign $1/2\sigma^2$ into x^2 .

(Refer Slide Time: 12:38)

Exponential Family of Distribution

- ❖ A family of distribution with the probability density function of the form

$$f(x; \theta) = a(\theta)b(x)\exp(c(\theta)t(x))$$

with $a(\theta) > 0$ and $c(\theta)$ as real functions of θ and $b(x) > 0$ is called an *exponential family of distribution*.

- ❖ Similarly a family of distributions

$$f(x; \theta) = a(\theta)b(x)\exp\left(\sum_{i=1}^k c_i(\theta)t_i(x)\right)$$

with $a(\theta), b(x)$ and $c_i(\theta)$ as specified above, is called the k -parameter exponential family.

- ❖ An exponential family of discrete RV's will have the probability mass function in the above forms

So now we can compare this expression with this distribution and that is there should be a theta term bx term and then exponential term in this summation form.

(Refer Slide Time: 12:47)

Example

- ❖ Suppose $X \sim N(\mu, \sigma^2)$ then

$$\begin{aligned} f(x; \mu, \sigma^2) &= \frac{1}{\sqrt{2\pi\sigma}} \exp\left(-\frac{1}{2\sigma^2}(x-\mu)^2\right) \\ &= \frac{1}{\sqrt{2\pi\sigma}} \exp\left(-\frac{1}{2\sigma^2}(x^2 + \mu^2 - 2\mu x)\right) \\ &= \frac{1}{\sqrt{2\pi\sigma}} \exp\left(-\frac{\mu^2}{2\sigma^2}\right) \exp\left(\frac{\mu}{\sigma^2}x - \frac{1}{2\sigma^2}x^2\right) \end{aligned}$$

- ❖ Thus $f(x; \mu, \sigma^2)$ belongs to a 2-parameter exponential family with

$$\theta = \begin{bmatrix} \mu \\ \sigma^2 \end{bmatrix},$$

$$a(\theta) = \frac{1}{\sqrt{2\pi\sigma}} \exp\left(-\frac{\mu^2}{2\sigma^2}\right), \quad b(x) = 1,$$

$$c_1(\theta) = \frac{\mu}{\sigma^2}, \quad c_2(\theta) = -\frac{1}{2\sigma^2},$$

$$t_1(x) = x^2, \text{ and } t_2(x) = x$$

So there we see that they are sum of two quantities here and this is the a theta term that is it is a function of Mue and Sigma Square and bx will be equal to 1 and then exponential term is this summation of these two quantities. So therefore f x, Mue, Sigma square belongs to a two parameter exponential family with theta that is parameter vector is equal to Mue Sigma square it comprises of Mue and Sigma square.

Then, a theta will be equal to 1 by root over 2 Pi Sigma into exponential minus Mue square by 2 Sigma square. So it is a function of Mue and Sigma Square and bx is equal to 1, c1 theta will be equal to this is Mue by Sigma square, c2 theta will be minus 1 by 2 Sigma Square. T1

x is equal to x and $t_2 x$ is equal to x square. So that way normal distribution is a member of the exponential family of distribution.

(Refer Slide Time: 13:58)

Complete Sufficient Statistic for Exponential Family of Distributions

❖ If $X_1, X_2, \dots, X_N$ are iid random variables, then

$$f(x_1, x_2, \dots, x_N; \theta) = a^N(\theta) \prod_{j=1}^N b(x_j) \exp \left(\sum_{i=1}^k c_i(\theta) \sum_{j=1}^N t_i(x_j) \right)$$

$$= a^N(\theta) b(\mathbf{x}) \exp \left(\sum_{i=1}^k c_i(\theta) T_i(\mathbf{x}) \right)$$

Define

$$T(\mathbf{x}) = \begin{bmatrix} T_1(\mathbf{x}) \\ T_2(\mathbf{x}) \\ \vdots \\ T_k(\mathbf{x}) \end{bmatrix} = \begin{bmatrix} \sum_{j=1}^N t_1(x_j) \\ \sum_{j=1}^N t_2(x_j) \\ \vdots \\ \sum_{j=1}^N t_k(x_j) \end{bmatrix}$$

Now we will see that, complete sufficient statistics for exponential family of distribution, can be found from the expression for the joint PDF itself. Suppose, if X_1, X_2 up to X_N are iid random variables of the exponential family, then we can write f X_1, X_2 up to X_N as a function of θ , that will be because there are N terms now this term will be a to the power N θ into the product b of x_j , j going from 1 to N into exponential i going from 1 to k , c_i θ into summation j going from 1 to N , $t_i x_j$.

So this way and this is the concern of x we are considering because there are n terms will get their expression like this; now, this we can write as a to the power N θ into b of x vector, because there is a product of x terms, so that we can write as b of x vector. Similarly here also, this summation also we can write as a statistic $T_i x$. Now my complete statistic will be Tx that is equal to $T_1 x, T_2 x$ up to $T_k x$, where $T_1 x$ will be the partial summation for j is equal to 1 to N , $T_1 x_i$ and similarly $T_2 x$ will be summation $T_2 x_j$, j going from 1 to N .

So in that way we can find out N statistic from this and they can be written in a vector from T of x vector.

(Refer Slide Time: 15:52)

Complete Sufficient Statistic for Exponential Family of Distributions ...

❖ Observe that

$$f(x_1, x_2, \dots, x_N; \theta) = a^N(\theta) \exp\left(\sum_{i=1}^k c_i(\theta) T_i(\mathbf{x})\right) b(\mathbf{x})$$

Hence, by factorization theorem $T(\mathbf{x})$ is a sufficient statistic.

❖ Next consider any function bounded function $g(T(\mathbf{X}))$. Then

$$Eg(T(\mathbf{X})) = \int_{-\infty}^{\infty} g(T(\mathbf{x})) b(\mathbf{x}) a^N(\theta) \exp\left(\sum_{i=1}^k c_i(\theta) T_i(\mathbf{x})\right) d\mathbf{x}$$

❖ The right-hand side of above is similar to multivariate Laplace transform which will be zero only when $g(T(\mathbf{x})) = 0, \forall \mathbf{x}$.

Therefore, $T(\mathbf{X})$ is a complete statistic.

↳

Now we observe that, this joint PDF can be written like this, a to the power N θ into exponential summation $c_i \theta T_i x$, i going from 1 to k , this is one vector. We see the function of $T_i x$ that is sufficient statistic $N \theta$ and into $b x$, there is another term $b x$ which is simply a function of x . So we can express joint PDF as a product of two vectors one vector is independent of any parameters, it is a simply a function of x and other factor is a function of the parameter and the estimator.

So therefore by factorization theorem $T x$ is a sufficient statistic, we have to prove that it is a complete statistic. Next consider any bounded function of the form $g T x$, then we have to find out expected value of $g T x$ to find out the completeness therefore E of $g T x$ that is integration from minus infinity to infinity of $g T x$, that is the function into PDF. Now PDF is $b x$ into a to the power n θ into exponential summation $c_i \theta T x$ into $b x$.

So this integration is the expected value of $g T x$. Now this right hand side because it is an exponential of Multiple terms so this can be interpreted as Multivariate laplace transform and which will be 0 only when $g T x$ is equal to 0 if this function is 0 only then this Multivariate Laplace transform can be equal to 0, therefore $g T x$ must be 0 with probability 1, therefore $T x$ is a complete statistic. So we saw that $T x$ is not only sufficient but it is also a complete statistic.

(Refer Slide Time: 18:08)

Complete Sufficient Statistic for Exponential Family of Distributions...

- ❖ We can express the likelihood function of iid random variables of the exponential family of distributions as

$$f(\mathbf{x}; \theta) = a^N(\theta) b(\mathbf{x}) \exp\left(\sum_{i=1}^k c_i(\theta) T_i(\mathbf{x})\right)$$

From this representation, we can find the complete sufficient statistics $T_i(\mathbf{x}), i=1, \dots, k$

- ❖ Hence we can find the MVUE

Now given a complete sufficient statistics for exponential family of distribution, we can find out the sufficient that is in this term itself we can express the likelihood function of iid random variables of the exponential family of distribution like this f of $\mathbf{x}$ theta is equal to a to the power N theta into $b\mathbf{x}$ into exponential summation c_i theta $T_i \mathbf{x}$, i going from i to k . From this representation we can find out the complete sufficient statistic $T_i \mathbf{x}$, for i is equal to 1 to k .

Hence we can find the MVUE as a function of this $T\mathbf{x}$ which is unbiased and we know that only one unbiased estimator exists and which has variance less than or equal to variance of any other unbiased estimator. Therefore that estimator will be MVUE.

(Refer Slide Time: 19:12)

Example

- ❖ Let $X_1, X_2, \dots, X_N$ be iid Gaussian with $X_i \sim N(\mu, \sigma^2)$ then

$$f(x_i; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma}} \exp\left(-\frac{1}{2\sigma^2}(x_i - \mu)^2\right) = \frac{1}{\sqrt{2\pi\sigma}} \exp\left(-\frac{\mu^2}{2\sigma^2}\right) \exp\left(-\frac{1}{2\sigma^2}x_i^2 + \frac{\mu}{\sigma^2}x_i\right)$$

$$\therefore f(\mathbf{x}; \mu, \sigma^2) = \left(\frac{1}{\sqrt{2\pi\sigma}} \exp\left(-\frac{\mu}{2\sigma^2}\right)\right)^N \exp\left(\frac{\mu}{\sigma^2} \sum_{i=1}^N x_i - \frac{1}{2\sigma^2} \sum_{i=1}^N x_i^2\right)$$

- ❖ Thus $f(\mathbf{x}; \mu, \sigma^2)$ belongs to a 2-parameter exponential family with $\theta = \begin{bmatrix} \mu \\ \sigma^2 \end{bmatrix}$.

$$\therefore T(\mathbf{X}) = \begin{bmatrix} \sum_{i=1}^N x_i \\ \sum_{i=1}^N x_i^2 \end{bmatrix} \text{ complete and sufficient}$$

MVUE will be given by

$$\hat{\mu} = \frac{1}{N} \sum_{i=1}^N x_i$$

$$\hat{\sigma}^2 = \frac{1}{N-1} \sum_{i=1}^N (x_i - \hat{\mu})^2$$

We can find the MVUE using this complete sufficient statistic.

So we will go back to example like again; let X_1, X_2 up to X_N be iid Gaussian with X_1 are distributed as normal distribution with mean μ and variance σ^2 and therefore if I consider only one element, that is x_1 only then its PDF is given by $\frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{1}{2\sigma^2}(x_1 - \mu)^2\right)$.

So this we can express in the exponential family of distribution like this $\frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{1}{2\sigma^2}(x_1 - \mu)^2\right) = \exp\left(-\frac{\mu^2}{2\sigma^2} + \frac{\mu x_1}{\sigma^2} - \frac{x_1^2}{2\sigma^2}\right)$. Now for N random variables the joint PDF as a function of μ, σ^2 which is the likelihood function.

We can write this as this vector to the power N and then exponential because of the product now all summation will come exponential μ by σ^2 into summation x_i , i going from 1 to N minus $\frac{1}{2\sigma^2}$ into summation x_i^2 , i going from 1 to N . So according to our earlier result this is an exponential family of distribution and here these are the statistics, these are the complete sufficient statistics.

Thus $f(x, \mu, \sigma^2)$ is a function of μ, σ^2 belongs to a two parameter exponential family with parameter vector is μ, σ^2 and $T(x)$ is given by first component is summation x_i , i going from 1 to N , second component is summation x_i^2 , i going from 1 to N and these two statistics are complete and sufficient. So therefore you can find out MVUE using this complete sufficient statistics.

So MVUE will be given by, MVUE will be given by parties we have to find out MVUE be the μ power is μ head. This is simple we have just divided by N , so that will be $\frac{1}{N}$ into summation x_i , i going from 1 to N and the other one for this we can so that this function will be given by σ^2 head square estimate that will be equal to $\frac{1}{N}$ into summation x_i^2 minus μ^2 whole square, i going from 1 to N , this is not N this is $N-1$.

Then this estimator will be unbiased and this is the MVUE for σ^2 head square. So that is we see that for exponential family of distribution we can find out the MVUE from the expression for the joint PDF itself.

(Refer Slide Time: 22:43)

Summary

- ❖ If $T(\mathbf{X})$ is a complete statistic then there is only one function $g(T(\mathbf{X}))$ which is unbiased.
- ❖ Lehmann Scheffe theorem
Suppose $T(\mathbf{X})$ is complete sufficient statistic for θ and $g(T(\mathbf{X}))$ is unbiased estimator based on $T(\mathbf{X})$. Then $g(T(\mathbf{X}))$ is the MVUE
- ❖ A family of distributions
$$f(x; \theta) = a(\theta)b(x)\exp\left(\sum_{i=1}^k c_i(\theta)T_i(x)\right)$$
with $a(\theta) > 0$ and $c_i(\theta)$ as real functions of θ and $b(x) > 0$ is called an exponential family of distributions.

Let us summarize first point we note that if TX is a complete statistic then there is only one function $g T x$ which is unbiased that we have established. Then Lehmann Scheffe theorems suppose, TX is a complete sufficient statistic for θ and $g TX$ is unbiased, then $g TX$ must be an MVUE. So if we have a function of complete sufficient statistic which is unbiased then that must be an MVUE.

Then we discussed about the family of distribution, which is known as the exponential family of distribution. So it is given by f of x θ is equal to $a(\theta) b(x)$ into exponential of k sums that is i going from 1 to k of $c_i(\theta) T_i(x)$. So this is the exponential family of distribution with $a(\theta) > 0$, $c_i(\theta)$ is a real function and $b(x)$ is also greater than 0 because this is a probability therefore this must be greater than 0 and this is the exponential family of distribution.

(Refer Slide Time: 24:11)

Summary...

- ❖ We can express the likelihood function of the iid random variables of the exponential family of distributions as

$$f(\mathbf{x}; \theta) = a^N(\theta) b(\mathbf{x}) \exp\left(\sum_{i=1}^k c_i(\theta) T_i(\mathbf{x})\right)$$

From this representation, we can find the complete sufficient statistics

$T_i(\mathbf{x}), i=1, \dots, K$ and hence the MVUE

We can express the likelihood function of the iid random variables of the exponential family of distribution in this form, that is the f of $\mathbf{x}$ vector θ as a function of θ this is the likelihood function or joint PDF this can be written as a to the power N θ into b of $\mathbf{x}$ vector exponential summation $c_i \theta T_i \mathbf{x}$, i going from 1 to k .

We can write in this form and from this representation we can find out the complete sufficient statistics as $T_i \mathbf{x}$, i going from 1 to k , we have found out their complete sufficient statistic from the exponential family of distribution and from that complete sufficient statistic we can find out the MVUE because we have to find out a function of $T_i \mathbf{x}$ which are unbiased that will give you the MVUE.

So that way we saw that we can find out the MVUE by employing two processes first one is if we can find out the expression for Cramer Rao Lower Bound, then that will give us to the MVUE. We next we saw that MVUE can be found out through complete sufficient statistics. But both this a process involve complicated analysis, we have to apply some simpler techniques to find out a good estimator for parameters, that we will be discussing in the next lecture, thank you.
