**Lecture – 18**  
**FIR Wiener Filter**

(Refer Slide Time: 00:41)

**Recall that**

- Wiener filter assumes a linear filter structure for the estimator and estimates the filter coefficients by applying the MMSE principle.

- Given random observations  $Y(n-M+1), Y(n-M+2), \dots, Y(n), \dots, Y(n+N)$ , the Wiener filtering problem is to

Minimize  $E \left( X(n) - \sum_{i=-N}^{M-1} h(i)Y(n-i) \right)^2$  over  $h(j), j = -N \text{ to } M-1$

- The minimum is given by the Wiener Hopf (WH) equation

$$R_{XY}(j) = \sum_{i=-N}^{M-1} h(i)R_Y(j-i), \quad j = -N, \dots, 0, 1, \dots, M-1$$

Hello students, welcome to this lecture on Wiener filter, recall that Wiener filter assumes a linear filter structure for the estimator and estimates the filter coefficients by applying the MMSE principle, this is the signal model;  $Y_n$  is equal to  $X_n + V_n$ , then it is pass through a linear filter to obtain the estimate  $\hat{X}_n$  and we have to determine the parameters of this linear filter.

Given the random observations  $Y_{n-M+1}, Y_{n-M+2}$  up to  $Y_n$ , then up to  $Y_{n+N}$ , the Wiener filtering problem is to minimize the mean square error, this is the mean square error over all filter coefficients  $h_j$ ;  $j$  going from  $-N$  to  $M-1$ , this is the Wiener filtering problem and the minimum is given by the Wiener Hopf equation that we established in the last lecture.

This is the relationship;  $R_{xyj}$  that is the cross correlation is given by the convolution of the impulse response sequence that is the filter coefficients and the autocorrelation function, so that way  $R_{xyj}$  is equal to summation  $h_i$  into  $R_Y j-i$ ;  $i$  going from  $-N$  to  $M-1$  and for  $j$  equal to  $-N$  up to  $M-1$ .

(Refer Slide Time: 02:26)

This lecture will examine the various interpretations of Wiener filter. It will discuss the FIR Wiener filter and the solution of the corresponding WH equations.

This lecture will examine the various interpretations of Wiener filter; it will discuss the FIR Wiener filter and the solution of the corresponding Wiener Hopf equations.

**(Refer Slide Time: 02:40)**

#### Interpretation of the optimality equations

❖ The optimality condition LMMSE formulation is given by

$$E \left( X(n) - \sum_{i=-N}^{M-1} h(i)Y(n-i) \right) Y(n-j) = 0, \quad j = -N, \dots, 0, 1, \dots, M-1$$

Thus,

$$E e(n) Y(n-j) = 0, \quad j = -N, \dots, 0, 1, \dots, M-1$$

This set of equations can be interpreted using our concepts of the linear algebra of RVs.

Let us interpret the optimality conditions for Wiener's filter; the optimality condition for LMMSE formulation is given by this expected value of this error into  $Y(n-j)$  that is equal to 0, for  $j$  is equal to  $-N$  up to  $M-1$ , thus we can write, this is the error part;  $E$  of  $e(n)$  into  $y(n-j)$  is equal to 0 for  $j$  going from  $-N$  to  $M-1$ . Now, this set of equations can be interpreted using our concepts of linear algebra of random variables.

V; so depth are the random variables can be interpreted as vectors in a vector space, so those interpretations will help us.

**(Refer Slide Time: 03:41)**

### Subspace projection and orthogonality principle

- ❖ Recall the inner product space of real random variables where the joint expectation  $E\{XY}$  is the inner product operation.
- ❖ Random variables  $X$  and  $Y$  are orthogonal iff  $E\{XY} = 0$
- ❖ The optimality equation 
$$E\{e(n)Y(n-j)\} = 0, \quad j = -N, \dots, 0, 1, \dots, M-1$$
 implies that the estimation error is orthogonal to each of the random observations.
- ❖ This principle of LMMSE estimation is called the *orthogonality principle*.

Recall the inner product space of real random variables, where the joint expectation  $E\{XY\}$  is the inner product operation,  $E\{XY\}$  defines an inner product, random variables  $X$  and  $Y$  are orthogonal if and only if  $E\{XY\}$  is equal to 0, this is the definition. Now, the optimality equation  $E\{e(n)Y(n-j)\} = 0$ , implies that the estimation error is orthogonal to each of the random observations.

For example,  $e(n)$  is orthogonal to  $Y(n-1)$  etc., this principle of LMMSE estimation is called the orthogonality principle that is error is orthogonal to each of the observation random variable.

**(Refer Slide Time: 04:44)**

### Subspace projection and orthogonality principle...

- ❖ Thus,  $e(n)$  is orthogonal to each of the random samples  $Y(n-j)$ ,  $j = -N, \dots, 0, 1, \dots, M-1$
- ❖ These random samples are linearly independent and spans a subspace  $W$ . The error  $e(n)$  is orthogonal to any member of this subspace:  $E\{e(n)w\} = 0, \quad \forall w \in W$
- ❖ Thus,  $\hat{X}(n) = \sum_{i=-N}^{M-1} h(i)Y(n-i)$  is an orthogonal projection on the subspace spanned by the data vectors.

Thus  $e(n)$  is orthogonal to each of the random samples  $Y(n-j)$ ;  $j$  going from  $-N$  to  $M-1$ , this random samples are linearly independent and spans a subspace  $W$ , all the random samples

when say subspace  $W$ , the error  $e_n$  is orthogonal to any member of this subspace,  $E$  of  $e_n$  into  $W$  will be equal to 0 for all  $W$  belonging to depth subspace capital  $W$ , thus  $\hat{X}_n$  which is given by this expression that is linear combination of  $Y_{n-1}$  is an orthogonal projection on the subspace spanned by the data vector.

So, this is important observation  $\hat{X}_n$  that is the Wiener estimation is an orthogonal projection on the subspace spanned by the data vectors.

**(Refer Slide Time: 05:52)**

Let us try to have the geometric interpretation of orthogonality principle; suppose we have to approximate a vector  $X$  as a scaled version of another vector  $Y$ , so this is a vector  $Y$ , this is vector  $X$ , we want to approximate  $X$  as the scaled version of  $Y$  that is we have to find  $aY$ , where  $a$  is a scalar. Now, if we drop a perpendicular, then this part will be the orthogonal projection and this error will be minimum.

So, the error  $e$  will be smallest, when  $e$  is perpendicular to  $Y$ , so that is the orthogonality principle, so we have to select this scalar multiple of  $Y$  in such a way that error is orthogonal to the data vector, this is the orthogonality principle.

**(Refer Slide Time: 06:51)**

### Minimum Mean Square Error

- ❖ The orthogonality principle can be used to determine the estimation error.
- ❖ The minimum mean-square estimation error is given by

$$\begin{aligned}
 E(e^2(n)) &= E e(n) \left( X(n) - \sum_{i=-N}^{M-1} h(i) Y(n-i) \right) \\
 &= E e(n) X(n) \quad \because \text{error is orthogonal to the estimate} \\
 &= E \left( X(n) - \sum_{i=-N}^{M-1} h(i) Y(n-i) \right) X(n) \\
 &= R_X(0) - \sum_{i=-N}^{M-1} h(i) R_{XY}(i)
 \end{aligned}$$

Now, this orthogonality principle can be used to obtain the estimation error because the minimum mean square error estimation error is given by this expression;  $E$  of  $e^2(n)$ , then that we can write  $E$  of  $e(n)$  into  $e(n)$  which can be expressed like this,  $X(n) - \sum_{i=-N}^{M-1} h(i) Y(n-i)$ ;  $i$  going from  $-N$  to  $M-1$ . Now, note that this part is orthogonal to error, so error is orthogonal to the estimate, this estimate.

Therefore, this will be simply  $E$  of  $e(n)$  into  $X(n)$  now, if I expand this  $e(n)$  that is  $X(n) - \sum_{i=-N}^{M-1} h(i) Y(n-i)$ ;  $i$  going from  $-N$  to  $M-1$ , then we get this will be  $E$  of and this expression into  $X(n)$  and if I write now,  $X(n)$  into  $X(n)$ , if we take the expected value we will get  $R_X(0)$ , similarly we will get the cross correlation function here by taking the expected values, so that way  $E$  of  $e^2(n)$  will be equal to  $R_X(0) - \sum_{i=-N}^{M-1} h(i) R_{XY}(i)$ .

(Refer Slide Time: 08:22)

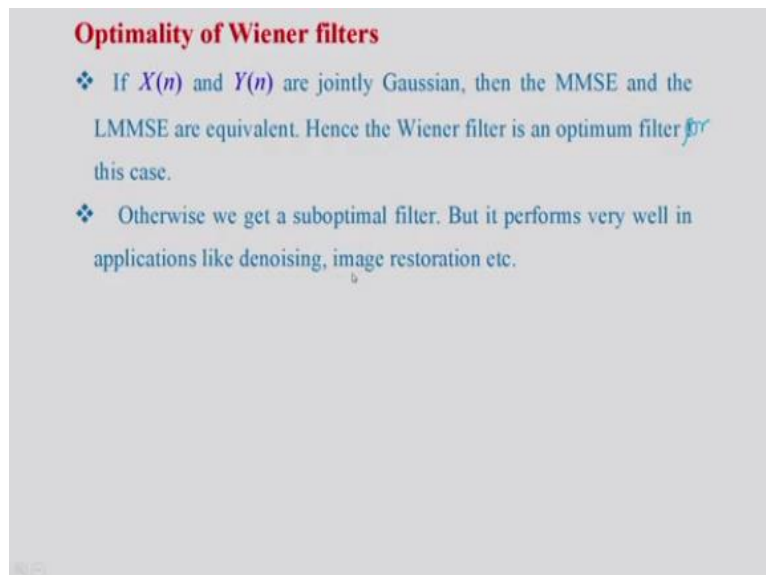

### Wiener filter as a correlation canceller

- ❖ Observe that
 
$$X(n) = \hat{X}(n) + e(n).$$
- ❖  $\hat{X}(n)$  involves cross-correlation between  $X(n)$  and  $Y(n)$  and hence is correlated with  $X(n)$ .
- ❖  $e(n)$  is uncorrelated with  $Y(n)$  because of the zero mean and orthogonality.
- ❖ LMMSE separates out that part of  $X(n)$  which is correlated with  $Y(n)$ . Hence, the Wiener filter can be also interpreted as a *correlation canceller*.

So, the orthogonality principle can be used to derive the mean square error of estimation, we will interpret Wiener filter also as a correlation canceller, observe depth  $X_n$  that is the unknown signal is the estimated signal plus error,  $\hat{X}_n + e_n$  now,  $\hat{X}_n$  involves cross correlation between  $X_n$ ,  $Y_n$  and hence  $\hat{X}_n$  will be correlated with  $X_n$ ,  $e_n$  is uncorrelated with  $Y_n$  because of the zero mean and orthogonality.

We know that  $e_n$  is orthogonal to  $Y_n$  but  $Y_n$  is 0 mean and consequently,  $e_n$  is also 0 mean, therefore orthogonal and 0 mean means that  $e_n$  is uncorrelated with  $Y_n$ , so this is very important that  $e_n$  is uncorrelated with  $Y_n$ , therefore LMMSE separates out a part of  $X_n$  which is correlated with  $Y_n$ , hence the Wiener filter can also be interpreted as a correlation canceller, whatever correlated part is there in the signal that will be cancelled out.

**(Refer Slide Time: 09:42)**

**Optimality of Wiener filters**

- ❖ If  $X(n)$  and  $Y(n)$  are jointly Gaussian, then the MMSE and the LMMSE are equivalent. Hence the Wiener filter is an optimum filter for this case.
- ❖ Otherwise we get a suboptimal filter. But it performs very well in applications like denoising, image restoration etc.

Now, question is whether the Wiener filter estimator is an optimum estimator, if  $X_n$  and  $Y_n$  are jointly Gaussian, then the MMSE and the linear MMSE are equivalent because that we have established in earlier lecture, hence the Wiener filter is optimum for the Gaussian case, otherwise we get a suboptimal filter but it performs very well in applications like denoising, image restoration etc., though it is a suboptimal filter because of its simplicity, it is very useful in practical applications.

**(Refer Slide Time: 10:27)**

### FIR Wiener Filter

- ❖ Consider an FIR filter of length  $M$ , characterized by the filter coefficients  $h(0), h(1), \dots, h(M-1)$

- ❖ The output of the filter to input  $Y(n)$  is given by

$$\hat{X}(n) = \sum_{i=0}^{M-1} h(i)Y(n-i)$$

- ❖ The filter coefficients are obtained by applying the orthogonality principle

$$E \left[ \overbrace{X(n) - \sum_{i=0}^{M-1} h(i)Y(n-i)}^{e(n)} Y(n-j) \right] = 0, \quad j = 0, 1, \dots, M-1$$

$$\sum_{i=0}^{M-1} h(i)R_y(j-i) = R_{xy}(j), \quad j = 0, 1, \dots, M-1$$

Thus we have a set of  $M$  normal equations

Now, we will discuss FIR Wiener filter. Consider an FIR filter of length  $M$  characterized by the filter coefficients  $h_0, h_1$  up to  $h_{M-1}$ , there are  $M$  coefficients, so that is a FIR filter of length  $M$ . The output of the filter to input  $Y_n$  is given by this relationship convolution relationship,  $\hat{X}_n$  is equal to summation  $h_i Y_{n-i}$ ;  $i$  going from 0 to  $M-1$ , this is the filter output.

And now, we have to find out these filter coefficients; the filter coefficients are obtained by applying the orthogonality principle, what is that; error is orthogonal to data, so  $E$  of  $\hat{X}_n$  minus summation  $h_i Y_{n-i}$ ;  $i$  going from 0 to  $M-1$  that is the error into  $Y$  of  $n-j$  will be equal to 0 for  $j$  is equal to 0, 1 up to  $M-1$ , so this will give now the Wiener Hopf equations that is if we take the expectation now, we will get summation  $i$  going from 0 to  $M-1$  of  $h_i$  into  $R_{yy}(j-i)$  will be equal to  $R_{xy}(j)$ , where  $j$  is equal to 0, 1 up to  $M-1$ .

So, these sets of equations are the  $M$  normal equations or Wiener Hopf equations and we have to solve these equations to find out the filter parameters.

**(Refer Slide Time: 12:19)**

### Matrix form of WH equations

❖ In matrix form, we have

$$\mathbf{R}_Y \mathbf{h} = \mathbf{r}_{XY}$$

where

$$\mathbf{R}_Y = \begin{bmatrix} R_Y(0) & R_Y(1) & \dots & R_Y(M-1) \\ R_Y(1) & R_Y(0) & \dots & R_Y(M-2) \\ \dots & \dots & \dots & \dots \\ R_Y(M-1) & R_Y(M-2) & \dots & R_Y(0) \end{bmatrix},$$

$$\mathbf{r}_{XY} = \begin{bmatrix} R_{XY}(0) \\ R_{XY}(1) \\ \dots \\ R_{XY}(M-1) \end{bmatrix} \quad \text{and} \quad \mathbf{h} = \begin{bmatrix} h(0) \\ h(1) \\ \dots \\ h(M-1) \end{bmatrix}$$

❖ Therefore,

$$\mathbf{h} = \mathbf{R}_Y^{-1} \mathbf{r}_{XY}$$

In the matrix form, we have  $\mathbf{R}_Y \mathbf{h}$  is equal to small  $\mathbf{r}_{XY}$ , this is the autocorrelation matrix of  $Y$  and this is the filter vector, this is the cross covariance vector, thus  $\mathbf{R}_Y$  is equal to this matrix,  $R_{Y0}, R_{Y1}$ , etc., up to  $R_{Y(M-1)}$  similarly, second row will be  $R_{Y1}, R_{Y0}$  up to  $R_{Y(M-2)}$  and so on similarly,  $\mathbf{r}_{XY}$  is the cross covariance vector and its elements are  $R_{XY}$  of 0,  $R_{XY}$  of 1 and so on up to  $R_{XY}$  of  $M-1$ .

And this is the vector representing the filter coefficients, there are  $M$  filter coefficients, so these  $M$  filter coefficients are represented by this vector, we can find  $\mathbf{h}$  by inverting this relationship  $\mathbf{R}_Y \mathbf{h}$  is equal to small  $\mathbf{r}_{XY}$ , therefore  $\mathbf{h}$  will be  $\mathbf{R}_Y$  inverse into small  $\mathbf{r}_{XY}$  vector, so this inverse matrix we have to find out.

**(Refer Slide Time: 13:34)**

### Matrix form of WH equations ...

❖ Such direct inversion is not easy when  $M$  is large.

❖ Note that

$$\mathbf{R}_Y = \begin{bmatrix} R_Y(0) & R_Y(1) & \dots & R_Y(M-1) \\ R_Y(1) & R_Y(0) & \dots & R_Y(M-2) \\ \dots & \dots & \dots & \dots \\ R_Y(M-1) & R_Y(M-2) & \dots & R_Y(0) \end{bmatrix}$$

is a special type of matrix: **symmetric Toeplitz matrix**. Elements of each of the diagonals, sub-diagonal and super-diagonals are equal. This property is exploited to develop fast algorithms to compute  $\mathbf{h}$ .

We shall discuss one such algorithm in a later lecture.

Such direct inversion is not easy when M is large because I know that Ry is an M by M matrix, so if M is large, inversion will be very complicated and now, let us examine this Ry matrix we see that all its diagonal elements are Ry0 similarly, this super diagonal elements will be Ry1, all elements will be Ry1 similarly, this is also all elements along this sub diagonal will be also Ry1.

So, that way, Ry is a special type of matrix what is known as the symmetric Toeplitz matrix, elements of each diagonal is same and elements of each super diagonal is same like that elements of each sub diagonal will be also same, this is not only Toeplitz but it is symmetric also, this one is Ry of 1, here also Ry of 1, so that way this is a symmetric Toeplitz matrix and this property is exploited to develop fast algorithm to compute h.

**(Refer Slide Time: 14:47)**

**Minimum Mean Square Error**

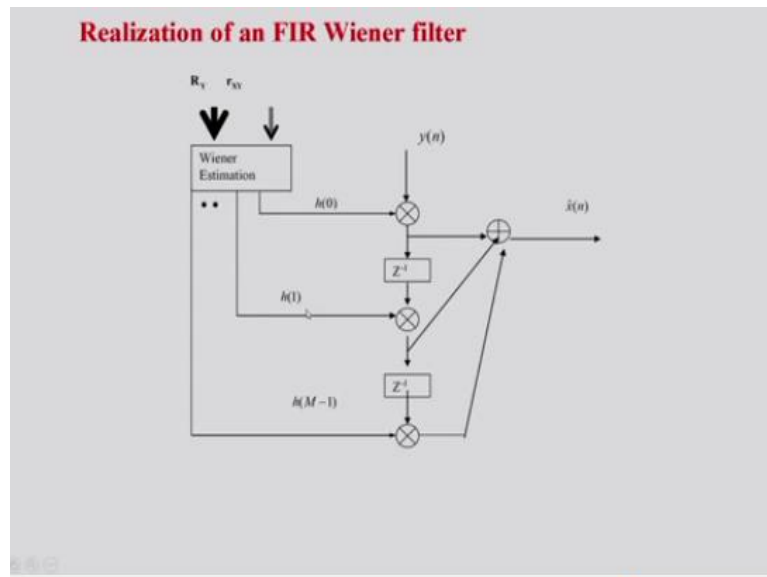

❖ The minimum mean-square estimation error is given by

$$\begin{aligned}
 E(e^2(n)) &= E\left(e(n) \left( X(n) - \sum_{i=0}^{M-1} h(i)Y(n-i) \right)\right) \\
 &= E(e(n)X(n)) \quad \because \text{error is orthogonal to the estimate} \\
 &= E\left( \left( X(n) - \sum_{i=0}^{M-1} h(i)Y(n-i) \right) X(n) \right) \\
 &= R_x(0) - \sum_{i=0}^{M-1} h(i)R_{xy}(i)
 \end{aligned}$$

We shall discuss one such algorithm in a later lecture, now this minimum mean square error of FIR filter, so that we have to find out, the minimum mean square estimation error is given by this expression; E of e square n that is E of en into X n minus this estimate and using the orthogonality principle as I shown earlier, it will be E of en into Xn, so therefore the mean square estimation error is equal to E of en into Xn.

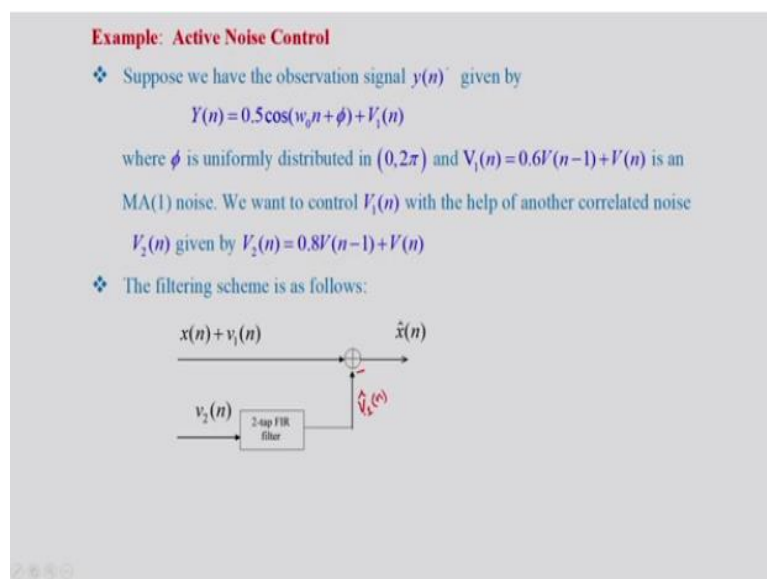

Now, I can expand en that is Xn minus summation hi into Y n – i; i going from 0 to M – 1 and then multiplied by Xn, if we simplify this will become Rx of 0 minus summation hi into Rxy i; i going from 0 to M – 1, this is the expression for mean square estimation error.

**(Refer Slide Time: 15:48)**

The FIR Wiener filter can be realized as follows, we have the autocorrelation matrix  $R_y$  and the cross correlation vector  $R_{xy}$  as input to the Wiener filter estimator and the estimator will compute the filter coefficients,  $h_0, h_1$  up to  $h_{M-1}$ , this is the input signal  $y_n$ , so this input signal  $y_n$  will be multiplied by  $h_0$ , then the delayed part will be multiplied by  $h_1$  and so on and all these outputs will be summed up and we will get  $\hat{x}_n$ .

**(Refer Slide Time: 16:34)**

So, this is the realization of FIR Wiener filter, let us consider one example, this is a very important application what is known as the active noise control. So, if we have to cancel the noise in a recording room, then this active noise control can be applied. Suppose, we have the observation signal  $y_n$  that is given by  $Y_n$  is equal to  $0.5 \cos(\omega_0 n + \pi) + V_1 n$ , there is a noise in the signal, where  $\pi$  is uniformly distributed in the interval 0 to  $2\pi$ .

And  $V1_n$  is equal to  $0.6 V_{n-1} + V_n$ , so this is known as a moving average model, MA 1 noise, so the signal  $Y_n$  is a cosine function plus some noise, we want to control  $V1_n$  with the help of another correlated noise  $V2_n$  which is given by  $V2_n$  is equal to  $0.8 V_{n-1} + V_n$  this is the  $V2_n$ ;  $V2_n$  and  $V1_n$  are correlated noise now, using the 2 tap FIR Wiener filter we will try to estimate  $V1$  and from this input because they are correlated, therefore we can estimate  $\hat{V1}_n$  here.

And this  $\hat{V1}$  and that estimated value that will be added here, so that it is positive and this is negative and this part will be cancel by this  $\hat{V1}$  and this is the active noise control, so that ultimately we will get the noise free part of this noisy signal, so this is the filtering scheme.

**(Refer Slide Time: 18:33)**

❖ The Wiener Hopf Equations are given by

$$\mathbf{R}_{v_2} \mathbf{h} = \mathbf{r}_{v_1 v_2}$$

where  $\mathbf{h} = [h(0) \ h(1)]^T$

and

$$\mathbf{R}_{v_2} = \begin{bmatrix} 1.64 & 0.8 \\ 0.8 & 1.64 \end{bmatrix} \text{ and } \mathbf{r}_{v_1 v_2} = \begin{bmatrix} 1.48 \\ 0.6 \end{bmatrix}$$

$$\mathbf{h} = \mathbf{R}_{v_2}^{-1} \mathbf{r}_{v_1 v_2}$$

$$\therefore \begin{bmatrix} h(0) \\ h(1) \end{bmatrix} = \begin{bmatrix} 0.9500 \\ -0.0976 \end{bmatrix}$$

And we can find the Wiener Hopf equations that is given by  $\mathbf{R}_{v_2}$  into  $\mathbf{h}$  that is the autocorrelation matrix of  $v_2$  into  $\mathbf{h}$  is equal to cross correlation vector  $\mathbf{r}_{v_1 v_2}$ , where  $\mathbf{h}$  is 2 length filter, so that way it is  $\mathbf{h}$  is equal to the vector composing of  $h_0$  and  $h_1$  now, we can compute  $\mathbf{R}_{v_2}$  from the model and these are given by 1.64, 0.8, 0.8, 1.64, this is the autocorrelation matrix of  $v_2$ .

And similarly,  $\mathbf{r}_{v_1 v_2}$ , this vector also we can compute from the model and  $\mathbf{r}_{v_1 v_2}$  is the vector comprising of 1.48 and 0.6, therefore we can find out now what will be  $\mathbf{h}$ ;  $\mathbf{h}$  is equal to  $\mathbf{R}_{v_2}$  inverse into small  $\mathbf{r}_{v_1 v_2}$  okay, so if we apply inverse this matrix and then multiply with this and we will get this result that is  $h_0$  is equal to 0.95 and  $h_1$  is equal to  $-0.976$ . So, now these are the filter coefficient corresponding to these 2 tap FIR filter.

And when we filter this noise sequence with this filter, we will get  $\hat{V}_1(n)$  and this will cancel out  $V_1(n)$ , so that way we get the noise cancel output.

(Refer Slide Time: 20:14)

**Summary**

- ❖ The Wiener filter optimality equation
 
$$E\{e(n)Y(n-j)\} = 0, \quad j = -N, \dots, 0, 1, \dots, M-1$$
 implies that the estimation error is orthogonal to each of the random observations. The estimator is an orthogonal projection of the signal on the subspace spanned by the random observations.
- ❖ Thus, the WH equations can be obtained by applying the orthogonality principle.
- ❖ The LMMSE separates out that part of  $X(n)$  which is correlated with  $Y(n)$ . Hence, the Wiener filter can be also interpreted as a *correlation canceller*.

Let us summarize the lecture; the Wiener filter optimality equations;  $E\{e(n)Y(n-j)\}$  is equal to 0 for  $j$  going from  $-N$  to  $M-1$ , these are the optimality equations for the general Wiener filter we have considered and this optimality conditions imply that the estimation error is orthogonal to each of the random observations. The estimator is an orthogonal projection of the signal on the subspace spanned by the random observations.

Thus the Wiener Hopf equations can be obtained by applying the orthogonality principle, we have also seen that the LMMSE separates out that part of  $X(n)$  which is correlated with  $Y(n)$ , hence the Wiener filter can be interpreted as a correlation canceller.

(Refer Slide Time: 21:19)

### Summary...

- ❖ The output of the FIR Wiener filter to input  $Y(n)$  is given by

$$\hat{X}(n) = \sum_{i=0}^{M-1} h(i)Y(n-i)$$

- ❖ Applying the orthogonality principle, we get the WH equations

$$\sum_{i=0}^{M-1} h(i)R_y(j-i) = R_{xy}(j), \quad j=0,1,\dots,M-1$$

- ❖ In matrix form, we have

$$\mathbf{R}_y \mathbf{h} = \mathbf{r}_{xy}$$

- ❖  $\mathbf{R}_y$  is a symmetric Toeplitz matrix.. This property is exploited to develop fast algorithms to compute  $\mathbf{h}$ .

The output of the FIR Wiener filter to input  $Y_n$  is given by this and this filter parameters or filter coefficients we have to find out using the orthogonality principle, applying the orthogonality principle we get the Wiener Hopf equations like this summation  $h_i$  into  $R_y j - i$ ;  $i$  going from 0 to  $M - 1$  is equal to  $R_{xy} j$  for  $j$  is equal to 0 to  $M - 1$ ,  $M$  equations are there and there are  $M$  unknowns.

Therefore, we can solve this set of equations to get the filter coefficients, in the matrix form we have  $\mathbf{R}_y \mathbf{h}$  is equal to  $\mathbf{r}_{xy}$  that is autocorrelation matrix into  $\mathbf{h}$  vector is equal to cross correlation vector and we also observed that  $\mathbf{R}_y$  is a symmetric Toeplitz matrix and this property is exploited to develop past algorithms to compute  $\mathbf{h}$ , thank you.
