**Levinson- Durbin algorithm**

- Given order of prediction  $M$  and  $R_Y(m)$ ,  $m = 0, 1, \dots, M$
- Initialize  $h_m(0) = -1$  for all  $m$
- $\varepsilon(0) = R_Y(0)$
- For  $m = 1, \dots, M$

$$k_m = \frac{\sum_{i=0}^{m-1} h_{m-1}(i) R_Y(m-i)}{\varepsilon(m-1)}$$

$$h_m(i) = h_{m-1}(i) + k_m h_{m-1}(m-i), i = 1, 2, \dots, m-1$$

$$h_m(m) = -k_m$$

$$\varepsilon_m = \varepsilon_{m-1}(1 - k_m^2)$$

Hello students welcome to this lecture linear prediction of signals. Let us review Levinson – Durbin algorithm we are given the order of prediction  $M$  and the autocorrelation functions  $R_Y(m)$   $m$  going from 0 to  $M$ . First, we have to initialize the predictor coefficients  $h_m(0) = -1$  for all  $m$  and epsilon 0 that is the mean square prediction error =  $R_Y(0)$  for prediction order 0. Now for  $M = 1$  up to  $M$ .

First we will determine the prediction coefficient  $k_m$  which is given by summation  $h_{m-1}(i)$  into  $R_Y(m-i)$ ,  $i$  going from 0 to  $m-1$  whole thing divided by epsilon  $m-1$  that is the mean square prediction error at stage  $m-1$  then we will update the filter coefficient  $h_m(i) = h_{m-1}(i) + k_m h_{m-1}(m-i)$  into  $h_{m-1}$  at  $m-i$   $i$  going from 1 to up to  $m-1$  and the last filter coefficient  $h_m(m)$  will be updated as  $-k_m$  and finally we will update the mean square prediction error  $\varepsilon_m = \varepsilon_{m-1}(1 - k_m^2)$  into  $1 - k_m^2$ . So  $k_m$  we have determined here.

### Review example on Levinson Durbin algorithm

Suppose the ACFs of a WSS process are given by

$$R_y(0) = 2.89, R_y(1) = 1.51 \text{ and } R_y(2) = 1.21$$

Find the second-order LP coefficients directly by matrix inversion and applying the Levinson Durbin algorithm.

Solution: WH equation in matrix form:

$$\begin{bmatrix} R_y(0) & R_y(1) \\ R_y(1) & R_y(0) \end{bmatrix} \begin{bmatrix} h(1) \\ h(2) \end{bmatrix} = \begin{bmatrix} R_y(1) \\ R_y(2) \end{bmatrix}$$

Therefore,

$$\begin{bmatrix} 2.89 & 1.51 \\ 1.51 & 2.89 \end{bmatrix} \begin{bmatrix} h(1) \\ h(2) \end{bmatrix} = \begin{bmatrix} 1.51 \\ 1.21 \end{bmatrix}$$

$$\therefore \begin{bmatrix} h(1) \\ h(2) \end{bmatrix} = \begin{bmatrix} 2.89 & 1.51 \\ 1.51 & 2.89 \end{bmatrix}^{-1} \begin{bmatrix} 1.51 \\ 1.21 \end{bmatrix} = \begin{bmatrix} 0.4178 \\ 0.2004 \end{bmatrix}$$

Let us consider the review example on Levinson -Durbin algorithm in the last class suppose the ACFs of a WSS process are given by this  $R_y$  of 0 is 2.89  $R_y$  of 1 is 1.51 and  $R_y$  of 2 is 1.21 find the second-order LP coefficients directly by matrix inversion and applying the Levinson-Durbin algorithm. So solution is like this we have to first establish the WH equation.

Wiener Hopf equation in matrix form that is given by this autocorrelation matrix into the coefficient vector is equal to the autocorrelation vector so that way here it is  $R_{y0}$ ,  $R_{y1}$ ,  $R_{y1}$ ,  $R_{y0}$  and similarly coefficients are  $h_1$ ,  $h_2$ . Therefore, if we substitute these values from here so autocorrelation matrix is 2.89,1.51,1.51,2.89 then multiply the coefficient vector  $h_1$ ,  $h_2$  and this must be equal to  $R_{y1}$  is 1.51,  $R_{y2}$  is 1.21 and we can directly take the matrix inverse and then multiply with this 1.51, 1.21 and we will get the filter coefficients  $h_1$  will be = 0.4178,  $h_2$  =0.2004.

**(Refer Slide Time: 04:11)**

In this lecture, we will

- ❖ derive recursive expressions for forward and backward prediction errors using the Levinson Durbin algorithm
- ❖ use them for an efficient implementation of the prediction error filter.

In this lecture, we will derive recursive expressions for forward and backward prediction errors using the Levinson-Durbin algorithm and we will use those prediction errors for an efficient implementation of the prediction error filter.

**(Refer Slide Time: 04:11)**

#### Forward and backward prediction errors

Suppose at time  $n$ ,

$e_m^f(n)$  = prediction error of  $m$ th order forward prediction and

$e_m^b(n)$  = prediction error of  $m$ th order backward prediction.

Clearly,

$$e_m^f(n) = y(n) - \sum_{i=1}^m h_m(i) y(n-i)$$

$$e_m^b(n) = y(n-m) - \sum_{i=1}^m h_m(m+1-i) y(n+1-i)$$

We want to establish the recursive relation between the prediction errors:

$$e_m^f(n) = e_{m-1}^f(n) + k_m e_{m-1}^b(n-1)$$

$$e_m^b(n) = e_{m-1}^b(n-1) + k_m e_{m-1}^f(n)$$

I will derive the expression for forward and backward prediction errors recursively. Let us denote  $e_m^f(n)$  that is the prediction error of a  $m$ th order forward prediction. Similarly corresponding backward prediction is given by  $e_m^b(n)$  that is the prediction error of a  $m$ th order backward prediction clearly forward prediction error  $e_m^f(n) = y(n) - \sum_{i=1}^m h_m(i) y(n-i)$  going from 1 to  $m$ .

So this is the  $m$ th order prediction, so the difference is the prediction error similarly  $e_{bn}$  that is the  $m$ th order backward prediction error now we are predicting  $y_{n-m}$  by this relationship. So, that way the backward prediction error is given by  $y_{n-m} - \text{backward prediction}$ , which is given by summation  $h_{m+1-i} y_{n+1-i}$  going from 1 to  $m$ . We want to establish the recursive relation between the prediction errors  $e_{fn} = e_{m-1,fn} + k_m \text{ times } e_{m-1,bn}$  similarly backward prediction error  $e_{bn} = e_{m-1,bn} + k_m \text{ times } e_{m-1,fn}$ .

So that way for our prediction error  $e_{fn}$  is given by the forward prediction error for order  $m-1$ ,  $e_{m-1,fn} + m \text{ times the backward prediction error of order } m-1$  which is delayed by 1. So this is a delayed version of the backward prediction error. Similarly backward prediction error also delayed version of the backward prediction error of order  $m-1 + k_m \text{ times forward prediction error of order } m-1$  at instant  $n$ .

**(Refer Slide Time: 07:08)**

**Recursion for prediction errors**

Proof: We have

$$e_m^f(n) = y(n) - \sum_{i=1}^m h_m(i) y(n-i)$$

Let us rewrite  $e_m^f(n)$  as

$$e_m^f(n) = Y(n) - h_m(n) y(n-m) - \sum_{i=1}^{m-1} h_m(i) y(n-i)$$

Applying Levinson Durbin recursion, we get

$$\begin{aligned} e_m^f(n) &= Y(n) + k_m Y(n-m) - \sum_{i=1}^{m-1} (h_{m-1}(i) + k_m h_{m-1}(m-i)) Y(n-i) \\ &= Y(n) - \sum_{i=1}^{m-1} h_{m-1}(i) Y(n-i) + k_m \left( Y(n-m) - \sum_{i=1}^{m-1} h_{m-1}(m-i) Y(n-i) \right) \\ &= e_{m-1}^f(n) + k_m e_{m-1}^b(n-1) \\ \therefore e_m^f(n) &= e_{m-1}^f(n) + k_m e_{m-1}^b(n-1) \end{aligned}$$

And now we will prove the recursion of forward error  $e_{fn} = y_n - \text{summation } h_{mi} y_{n-i}$  i go in from 1 to  $m$  and now we can write  $e_{mf}$  and as  $y_n$  minus that last coefficient here I am taking out  $h_m$  and into  $y_{n-m}$  so when we put  $m$  here  $h_{mm}$  into  $y_{n-m}$  that I am taking it out and then summation is same  $i$  into  $y_{n-i}$  i going from 1 to  $m-1$ . Now we know that this  $-h_{mn} = k_m$  by definition and here we can apply the Levinson - Durbin recursion.

Applying Levinson- Durbin recursion we get  $e_m^b(n) = y(n-m) - \sum_{i=1}^{m-1} h_{m-i} y(n-i) + k_m e_{m-1}^b(n)$  into  $y(n-m) - \sum_{i=1}^{m-1} h_{m-i} y(n-i) + k_m e_{m-1}^b(n)$  going from 1 to  $m-1$  of now we are substituting  $h_{m-i} = \sum_{j=1}^{m-i} h_{m-i-j} y(n-j) + k_{m-i} e_{m-i-1}^b(n)$  so this is the recursion we are using for  $h_{m-i}$  which is true for  $i = 1$  to  $m-1$  and then whole thing into  $y(n-m) - \sum_{i=1}^{m-1} h_{m-i} y(n-i) + k_m e_{m-1}^b(n)$ . So this is the relationship we get from here now we can bring these terms containing  $k_m$  together so that way  $y(n-m)$  minus.

This will bring here,  $y(n-m) - \sum_{i=1}^{m-1} h_{m-i} y(n-i) + k_m e_{m-1}^b(n)$  into  $y(n-m) - \sum_{i=1}^{m-1} h_{m-i} y(n-i) + k_m e_{m-1}^b(n)$  going from 1 to  $m-1$  +  $k_m$  times  $y(n-m) - \sum_{i=1}^{m-1} h_{m-i} y(n-i) + k_m e_{m-1}^b(n)$  minus this term  $\sum_{i=1}^{m-1} h_{m-i} y(n-i)$  going from 1 to  $m-1$ . Now this part is the forward prediction error of order  $m-1$ . So this expression will be  $e_{m-1}^f(n) + k_m e_{m-1}^b(n)$  now this term is  $y(n-m)$  that is the true value, and this is the backward predicted value. So that where this is the backward prediction error at  $n-1$ .

So that way this will be  $k_m$  times  $e_{m-1}^b(n)$  and  $-1$  because this is  $m-1$  at order prediction and prediction starts at  $y(n-1)$  so that way this is backward prediction at time  $n-1$ . So that way we have arrived in relationship that  $e_m^b(n) = e_{m-1}^f(n) + k_m e_{m-1}^b(n)$  at  $n-1$ .

**(Refer Slide Time: 10:38)**

### Recursion of prediction errors...

Similarly, using the backward prediction error

$$e_m^b(n) = y(n-m) - \sum_{i=1}^m h_m(m+1-i) y(n+1-i)$$

we can show that

$$e_m^b(n) = e_{m-1}^b(n-1) + k_m e_{m-1}^f(n)$$

Thus, we have established the recursive relations:

$$e_m^f(n) = e_{m-1}^f(n) + k_m e_{m-1}^b(n-1)$$

$$e_m^b(n) = e_{m-1}^b(n-1) + k_m e_{m-1}^f(n)$$

These errors have interesting properties which are very useful.

Similarly, using the backward prediction error which is given by  $e_m^b(n) = y(n-m) - \sum_{i=1}^m h_m(m+1-i) y(n+1-i)$  same  $m+1-i$  into  $y(n+1-i)$  going from 1 to  $m$ . This is the backward prediction error and now here also we will be using the Levinson-Durbin recursion then we can show that  $e_m^b(n) = e_{m-1}^b(n-1) + k_m e_{m-1}^f(n)$ . Thus we have established a recursive relations  $e_m^b(n) = e_{m-1}^b(n-1) + k_m e_{m-1}^f(n)$ .

$k_m$  times  $e_{m-1} b_n - 1$ . Similarly  $e_m b_n = e_{m-1} b_n - 1 + k_m$  times  $e_m - 1 f_n$  and these errors have interesting properties which are very useful for practical purposes.

(Refer Slide Time: 11:50)

**Alternative expression for the reflection coefficients**

- ❖ Recall that  $k_m$  was defined in Levinson Durbin recursion as  $k_m = -h_m(m)$ .
- ❖ Since  $k_m$  is derived from the optimal LP coefficients and hence are optimal with respect to the mean square prediction error.
- ❖ Consider the forward prediction error

$$e_m^f(n) = e_{m-1}^f(n) + k_m e_{m-1}^b(n-1)$$

We have

$$E(e_m^f(n))^2 = E(e_{m-1}^f(n) + k_m e_{m-1}^b(n-1))^2$$

For to be optimal

$$\frac{dE(e_m^f(n))^2}{dk_m} = 0$$

Now we will derive an alternative expression for the reflection coefficients in terms of the forward and backward prediction errors. Recall that  $k_m$  was defined in the Levinson - Durbin recursion as  $k_m = -h_m(m)$ . So if it is a  $m$ th order prediction that last coefficient is with negative sign is  $k_m$ . Since  $k_m$  is derived from the optimal LP coefficients it is optimal with respect to the mean square prediction error.

Now let us consider the forward prediction error that is  $e_m f_n = e_{m-1} f_n + k_m$  times  $e_{m-1} b_n - 1$  we have a of  $e_m f_n$  whole square that is the mean square prediction error =  $E$  of  $e_{m-1} f_n + k_m$  times  $e_{m-1} b_n - 1$  whole square. So this is the forward prediction error and for  $k_m$  to be optimal the derivative of the mean squared with respect to  $k_m$  must be  $= 0$ .

(Refer Slide Time: 13:11)

### Expression for $k_m$

Thus,

$$\begin{aligned} \frac{d}{dk_m} E(e_{m-1}^f(n) + k_m e_{m-1}^b(n-1))^2 &= 0 \\ \therefore E(e_{m-1}^f(n) + k_m e_{m-1}^b(n-1)) e_{m-1}^b(n-1) &= 0 \\ \Rightarrow k_m &= - \frac{E(e_{m-1}^f(n) e_{m-1}^b(n-1))}{E(e_{m-1}^b(n-1))^2} \end{aligned}$$

We can get a similar expression by considering  $E(e_m^b(n))^2$

$$k_m = - \frac{E(e_{m-1}^f(n) e_{m-1}^b(n-1))}{E(e_{m-1}^f(n))^2}$$

Thus we get the derivative of  $E(e_{m-1}^f(n) + k_m e_{m-1}^b(n-1))^2 = 0$  so we take the derivative so it is a derivative of this and then again inside it is a function so that way we will get  $E(e_{m-1}^f(n) + k_m e_{m-1}^b(n-1)) e_{m-1}^b(n-1)$  now this expression when we take the derivative with respect to  $k_m$  we will get  $e_{m-1}^b(n-1)$  that must be  $= 0$  implies that  $k_m$  is  $= - E(e_{m-1}^f(n) e_{m-1}^b(n-1))$  divided by  $E(e_{m-1}^b(n-1))^2$  whole square.

We can get a similar expression by considering the mean square backward prediction error and in that case,  $k_m$  can be shown to be like this. So same value of  $k_m$  we can either get through this expression or this expression.

**(Refer Slide Time: 14:34)**

### Interpretation of the reflection coefficients

We have,

$$k_m = - \frac{E(e_{m-1}^f(n) e_{m-1}^b(n-1))}{E(e_{m-1}^b(n-1))^2}$$

❖ Denominator is MMSPE and is a normalizing term.

❖  $e_{m-1}^f(n)$  is the residual part of  $Y(n)$  after removing part correlated with  $Y(n-1), Y(n-2), \dots, Y(n-m+1)$

❖  $e_{m-1}^b(n-1)$  is the residual part of  $Y(n-m)$  after removing part correlated with  $Y(n-1), Y(n-2), \dots, Y(n-m+1)$

❖ Thus, the numerator  $E(e_{m-1}^f(n) e_{m-1}^b(n-1))$  is the cross-correlation of  $Y(n)$  and  $Y(n-m)$  after the correlations due to the intermediate data  $Y(n-1), Y(n-2), \dots, Y(n-m+1)$  are removed. Hence  $k_m$  is called the PARCOR coefficient.

Now let us try to interpret the reflection coefficient  $k_m$  so  $k_m$  is given by we are considering the this expression  $k_m$  is given by this the denominator is MMSPE and is a normalizing term  $e_{m-1}^b f_n$  is the residual part of  $Y_n$  after removing the correlation with  $Y_{n-1}$   $Y_{n-2}$  etc up to  $Y_{n-m+1}$ . So after removing the correlation of the intermediate data whatever residual is there that is  $e_{m-1}^b f_n$  similarly  $e_{m-1}^b b_{n-1}$  is the residual part of  $Y_{n-m}$  after removing the part correlated with  $Y_{n-1}$   $Y_{n-2}$  up to  $Y_{n-m+1}$  same set of data.

Thus the numerator this expression  $e_{m-1}^b f_n$  into  $e_{m-1}^b b_{n-1}$  is the cross correlation of  $Y_n$  and  $Y_{n-m}$  after the correlation due to the intermediate data already moved. Hence  $k_m$  is called the partial correlation coefficient. So you have remove the correlation because the intermediate data and then you were determining the correlation between  $e_{m-1}^b f_n$  and  $e_{m-1}^b b_{n-1}$  so these are the residuals after removing the correlation due to the intermediate data. So that is right the name is PARCOR coefficient.

**(Refer Slide Time: 16:40)**

### Whiteness of backward prediction errors

Consider two backward prediction errors:

$$e_m^b(n) = y(n-m) - \sum_{i=1}^m h_m(m+1-i) y(n+1-i)$$

$$\text{and } e_k^b(n) = y(n-k) - \sum_{i=1}^k h_k(k+1-i) y(n+1-i) \quad 0 < k < m$$

$$E e_m^b(n) y(n+1-i) = 0, \quad 1 \leq i \leq m$$

$$\therefore E e_m^b(n) y(n+1-i) = 0, \quad 1 \leq i \leq k < m$$

$$\Rightarrow E e_m^b(n) e_k^b(n) = 0, \quad 1 \leq k < m$$

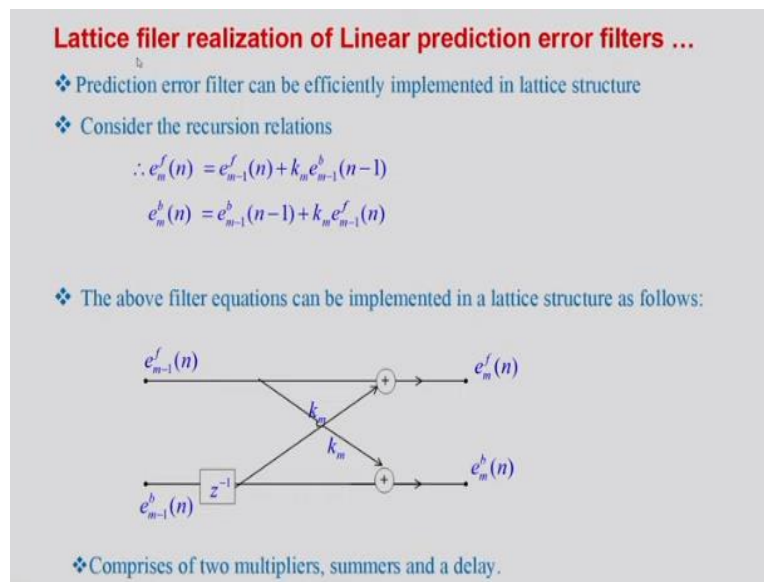

❖ Thus, the backward prediction error signal white and is efficient for the compression purpose.

Now we will prove one important result witness update backward prediction errors consider 2 backward prediction errors suppose  $e_m^b(n) = y(n-m) - \sum_{i=1}^m h_m(m+1-i) y(n+1-i)$  going from 1 to m and suppose at kth order backward prediction error  $e_k^b(n) = y(n-k) - \sum_{i=1}^k h_k(k+1-i) y(n+1-i)$ , i going from 1 to k. So this is for suppose k is some number between 0 and m clearly from this  $E$  of  $e_m^b(n)$  is orthogonal to  $y(n+1-i)$ , i lying between 1 and m because of the linear minimum mean square error estimation.

And therefore since our  $k$  is less than  $m$  so  $E$  of  $e_{m,n}$  into  $y$  and  $+1 - i$  will be  $= 0$  for all  $i$  less than  $= k$  where  $k$  is less than  $m$ . Now this backward prediction error is the combination of data between  $1$  and  $k$ . So therefore from this expression we will get that this backward prediction error  $E_{m,n}$  will be orthogonal to  $e_{k,n}$  for all  $l$  lying within  $1$  and  $m$  because this  $e_{k,n}$  is a linear combination of  $y_{n+1-i}$ ,  $i$  lying between  $1$  to  $k$ . Therefore, expected value of  $E_{m,n}$  into  $e_{k,n}$  will be  $= 0$  for  $k$  lying between  $1$  and  $m$  thus the backward prediction error signal is white and is efficient for the compression purpose.

**(Refer Slide Time: 19:00)**

Now let us see Lattice filter realization of linear prediction error filters, prediction error filter can be efficiently implemented in lattice structure consider the recursion relations  $e_{m,n}^f = e_{m-1,n}^f + k_m e_{m-1,n-1}^b$  and similarly  $e_{m,n}^b = e_{m-1,n-1}^b + k_m e_{m-1,n}^f$ . The above filter equations can be implemented in a lattice structure as follows. Because this is the output of the filter section that is  $e_{m,n}^f$  and input is  $e_{m-1,n}^f + e_{m-1,n-1}^b$ .

Therefore  $e_{m,n}^f$  is the sum of  $e_{m-1,n}^f$  and  $k_m$  times  $e_{m-1,n-1}^b$ . So this we can write using filter elements like  $e_{m,n}^f = e_{m-1,n}^f$  plus this is the delayed version of  $e_{m-1,n}^b$ . So here output will be  $e_{m-1,n-1}^b$  and that will be multiplied by  $k_m$  and it will be added so that way  $e_{m,n}^f$  is the sum of this signal plus this signal delayed by 1 unit and then multiplied by  $k_m$ . So that way we see that this expression can be implemented by this part.

Similarly this backward prediction can be implemented and is equal to this delayed backward prediction error this plus the forward prediction error multiplied by  $k_m$ . So that way  $e_{m,n}$  will be equal to this part  $e_{m-1,n-1}$  because it is delayed here +  $e_{m-1,n}$  multiplied by  $k_m$  and that will give us  $e_{m,n}$  and so this is a simple implementation because same multiplier is used here and there is there somewhere here somewhere here and then this delay unit. Thus we have seen that this recursive relation can be implemented by this filter section.

**(Refer Slide Time: 21:58)**

How to initialize this lattice we know that suppose derivation order prediction in that case forward prediction error will be  $Y_n - 0$  that is  $= Y_n$  similarly backward prediction error also will be  $= Y_n - 0$  that  $= Y_n$  hence  $e_0^f = e_0^b = Y_n$  and this can be the initial input and the first lattice section will be as follows. So  $Y_n$  it will be passing through this path it will be passing through this path and then when delayed version multiplied by  $k_1$  is added here you will get  $e_1^f$  and similarly when delayed version and this part  $Y_n$  multiplied by  $k_1$  is added here this sum will be  $e_1^b$ . So that way initialization also we have seen.

**(Refer Slide Time: 23:02)**

### Lattice filter realization for $M$ th order LP error filter

❖ The lattice filter generating the forward and backward prediction errors is shown above.

Therefore complete filter can be realized by cascading all these sections like this. So input will be  $Y[n]$  here and then first checks on output will be suppose  $e_1^f(n)$  and here  $e_1^b(n)$  and like that suppose last section because we are interested to find out the  $m$ th order prediction errors, So both forward and backward prediction errors will be obtained by the last section. So this last section input will be  $e_{M-1}^f(n) + e_{M-1}^b(n)$  thus we can get the forward and backward prediction errors using this lattice filter structure with  $y[n]$  at the input.

(Refer Slide Time: 24:01)

### Advantage of Lattice Structure

- ❖ Modular structure can be extended by cascading another section. New stages can be added without modifying the earlier stages.
- ❖ Same elements are used in each stage. So efficient for VLSI implementation.
- ❖ Numerically efficient as  $|k_m| < 1$ .
- ❖ The backward prediction errors being white can be efficiently stored in hardware implementation.
- ❖ Inverse filter can be easily implemented

So this diagram shows the latest filter implementation the Lattice structure has several advantages it is a modular structure it can be extended by cascading another section. New stages can be added without modifying the earlier stages. Same elements are used in each stage that is

multiplier and some are used so efficient for VLSI implementation. It is numerically efficient because this came coefficient reflection coefficient magnitude is always less than 1 therefore quantization error will be less here.

The backward prediction errors being white can be efficiently stored in a in Hardware implementation and inverse filter can also easily be implemented these are some advantages of this lattice realization.

**(Refer Slide Time: 25:00)**

### Summary

- ❖ The Levinson Durbin algorithm can be used to compute LP coefficients.
- ❖ The Levinson Durbin recursion is used to derive the recursion of prediction errors
 
$$e_m^f(n) = e_{m-1}^f(n) + k_m e_{m-1}^b(n-1)$$

$$e_m^b(n) = e_{m-1}^b(n-1) + k_m e_{m-1}^f(n)$$
- ❖  $k_m$  measures the cross-correlation between  $Y(n)$  and  $Y(n-m)$  after removing the correlation because of the intermediate data  $Y(n-1), Y(n-2), \dots, Y(n-m+1)$
- ❖ The backward prediction error  $e_m^b(n)$  for different  $m$  are uncorrelated.
- ❖ The prediction error filter can be efficiently implemented in the lattice structure.

Let us summarize this lecture the Levinson-Durbin algorithm can be used to compute LP coefficients. The Levinson Darwin recursion is used to directly recursion of the prediction error these are the expression we obtained. The reflection coefficient  $k_m$  measures the cross correlation between  $Y_n$  and  $Y_{n-m}$  after removing the correlation because of the intermediate data  $Y_{n-1} Y_{n-2}$  up to  $Y_{n-m+1}$ .

The backward prediction error  $e_{mbn}$  for different  $m$  are uncorrelated that also we established. The prediction error filter can be efficiently implemented in the lattice structure.

### Looking ahead

- ❖ So far we have assumed that the random signals are WSS so that they are characterized by the autocorrelation and cross-correlation functions.
- ❖ The Wiener filters are time invariant because of the above assumption.
- ❖ Practical signals are non-stationary and the optimal filter should be time varying.
- ❖ One solution is the family of filters known as the adaptive filters.
- ❖ We will study these filters next.

Looking ahead so far, we have assumed that the random signals are WSS wide-sense stationary so that they are characterized by the autocorrelation and cross correlation functions. The wiener filters are time invariant because of the above assumption. Practical signals are non-stationary, and the optimal filter should be time varying. One solution is the familiar of filters known as the adaptive filter we will study these filters next. Thank you.
