Recall that

- ❖ The LMS updates the filter weights according to
 
$$\mathbf{h}(n+1) = \mathbf{h}(n) + \mu e(n) \mathbf{y}(n)$$
- ❖ Under independence assumption, the LMS algorithm is convergent in the mean if the step size parameter  $\mu$  satisfies the condition:
 
$$0 < \mu < \frac{2}{\lambda_{\max}}$$
- $E\mathbf{h}(n)$  converges to the corresponding Wiener filter weights.
- ❖ Under the independence assumption the MSE  $\epsilon(n)$  converges if and only if
 
$$0 < \mu < \frac{2}{\lambda_{\max}} \text{ and } \sum_{i=1}^M \frac{\mu \lambda_i}{2 - \mu \lambda_i} < 1$$

Hello students. Welcome to this lecture on Adaptive Filters. Recall that the LMS algorithm updates the filter with according to this relation  $\mathbf{h}(n+1) = \mathbf{h}(n) + \mu e(n) \mathbf{y}(n)$  where  $\mathbf{y}(n)$  is the data vector,  $e(n)$  is the error and  $\mathbf{h}(n)$  is the filter coefficient at instant  $n$ . Under the independent assumption the LMS algorithm is convergent in the mean if the step size parameter  $\mu$  satisfy this conditions we know that  $\mu < 2/\lambda_{\max}$ .

And  $E\mathbf{h}(n)$  converges to the corresponding Wiener filter weights as  $\mathbf{h}(n)$  tends to infinity  $E\mathbf{h}(n)$  converges to the corresponding Wiener filter weights. Under the independent assumption the MSE  $\epsilon(n)$  converges if and only if again first condition is like this  $\mu < 2/\lambda_{\max}$  and the second condition summation  $\sum_{i=1}^M \frac{\mu \lambda_i}{2 - \mu \lambda_i} < 1$ .

(Refer Slide Time: 02:11)

### Recall ...

- ❖ Convergence of the LMS algorithm is slow when the eigenvalue spread of the autocorrelation matrix is large.

- ❖ The misadjustment factor

$$\frac{\epsilon_{\text{excess}}}{\epsilon_{\text{min}}} \approx \frac{1}{2} \mu \text{Trace}(\mathbf{R}_y)$$

is large unless  $\mu$  is much smaller.

This lecture will cover variants of the LMS algorithm addressing the above issues.

We will also see two simplifications of the LMS algorithm for faster implementation.

We also noted that the convergence of the LMS algorithm is slow when the eigenvalue spread of the autocorrelation matrix is large and there is a misadjustment factor that is the ratio of the excess mean square error divided by minimum mean square error corresponding to Wiener filter and that is approximately = half of mu times Trace of  $\mathbf{R}_y$ . Therefore, this misadjustment factor will be large if mu is large therefore mu should be small.

This lecture will cover the variance of LMS algorithm addressing the above issues convergence issues. We also see two simplifications of the LMS algorithm for faster implementation.

**(Refer Slide Time: 03:10)**

### Leaky LMS (LLMS) Algorithm

- ❖ We saw that the LMS iteration is convergent in the mean if the step size parameter  $\mu$  satisfies the convergence condition in terms of the eigen values of the  $\mathbf{R}_y$  matrix.
- ❖ If some eigen values are small, the convergence will be slow. To improve the convergence rate, the small eigen values may be enhanced..
- ❖ One method to improve the convergence is the leaky LMS (LLMS) algorithm. It uses a leakage factor to control the values of the filter coefficients in LMS updation:

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \mu e(n) \mathbf{y}(n)$$

First we will start with the leaky LMS LLMS algorithm. We saw that the LMS iteration is convergent in the mean if the step size parameter mu satisfies the convergence condition in

terms of the eigen values of  $\mathbf{R}\mathbf{Y}$  matrix. So the convergence is determined by the eigen values of  $\mathbf{R}\mathbf{Y}$  matrix. If some eigen values are small the convergence will be slow. Thus if anyone of the eigen values is small then the rate of convergence will be affected.

Therefore, to improve the convergence rate the small eigen values maybe enhanced. One method to improve the convergent is the leaky LMS LLMS algorithm. It uses a leakage factors to control the values of the filter coefficient in LMS updation this is the LMS updation  $\mathbf{h}(n+1) = \eta \mathbf{h}(n) + \mu \mathbf{e}(n) \mathbf{y}(n)$  vector.

**(Refer Slide Time: 04:35)**

**Cost function LLMS Algorithm**

- ❖ The cost function of the leaky LMS algorithm includes a regularization term. Thus, the minimization problem can be expressed as

$$\text{Minimize } e^2(n) + \alpha \|\mathbf{h}(n)\|^2 \text{ with respect to } \mathbf{h}(n)$$

where  $\|\mathbf{h}(n)\|^2 = \mathbf{h}^T(n)\mathbf{h}(n)$ ,  
 $\alpha$  is a positive quantity  
and  $e(n) = d(n) - \mathbf{h}^T(n)\mathbf{y}(n)$

- ❖ The term  $\alpha \|\mathbf{h}(n)\|^2$  ensures that  $\mathbf{h}(n)$  decreases faster.
- ❖  $0 < \alpha < 1$
- ❖ The method of gradient descent is applied to minimize the above cost function

Let us examine the cost function for LLMS algorithm the cost function of the leaky LMS algorithm includes a regularization term thus the minimization problems can be expressed as minimize  $e^2(n) + \alpha \|\mathbf{h}(n)\|^2$  with respect to  $\mathbf{h}(n)$  where  $\|\mathbf{h}(n)\|^2 = \mathbf{h}^T(n)\mathbf{h}(n)$  this is the  $(\cdot)$  norm  $\alpha$  is a positive quantity and  $\mathbf{e}(n)$  is  $d(n)$  minus that is the desired signal -  $\mathbf{h}^T(n)\mathbf{y}(n)$  this is the filter output.

So here  $e^2(n)$  is the cost function corresponding to the LMS algorithm and this term  $\alpha \|\mathbf{h}(n)\|^2$  is the regularization term. The term  $\alpha \|\mathbf{h}(n)\|^2$  ensures that  $\mathbf{h}(n)$  decreases faster because if it tries to increase because of this positive value the cost function will increase so our aim to minimize the cost function.  $\alpha$  is taken between 0 and 1 and the method of gradient descent is applied to minimize the above cost function just like in the case of LMS algorithm.

**(Refer Slide Time: 06:18)**

### LLMS iteration

- ❖ The corresponding update equation is given by

$$\mathbf{h}(n+1) = (1 - \mu\alpha)\mathbf{h}(n) + \mu\alpha e(n)\mathbf{y}(n)$$

where  $\mu\alpha$  is chosen to be less than 1

- ❖ Using the independence assumption, we can show that

$$\lim_{n \rightarrow \infty} E[\mathbf{h}(n)] = (\mathbf{R}_Y + \alpha\mathbf{I})^{-1} \mathbf{r}_{dY}$$

- ❖ We see that the matrix  $\alpha\mathbf{I}$  is added to the correlation matrix of LMS iteration.

- ❖ We also note that  $\alpha\mathbf{I}$  is the autocorrelation matrix of a white noise with variance  $\alpha$ . Thus the regularization process adds a white noise component to  $\mathbf{y}(n)$ .

$$\begin{bmatrix} \alpha & 0 & 0 & \dots \\ 0 & \alpha & 0 & \dots \\ 0 & 0 & \alpha & \dots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix} = \alpha\mathbf{I}$$

The corresponding update equation is given by  $\mathbf{h}_{n+1} = (1 - \mu\alpha)\mathbf{h}_n + \mu\alpha e_n \mathbf{y}_n$  vector. So the leakage term is introduced here now where  $\mu\alpha$  is chosen to be less than 1 because of this factor is to be positive so  $\mu\alpha$  must be less than 1. Using the independence assumption we can show that limit of  $E[\mathbf{h}_n]$  as  $n$  tends to infinity will be  $=(\mathbf{R}_Y + \alpha\mathbf{I})^{-1} \mathbf{r}_{dY}$ .

Limit  $E[\mathbf{h}_n]$  as  $n$  tends to infinity  $=(\mathbf{R}_Y + \alpha\mathbf{I})^{-1} \mathbf{r}_{dY}$  this is the cross correlation between  $\mathbf{d}$  and  $\mathbf{Y}$ . Note that this is different from the corresponding Wiener filter solution. We see that the matrix  $\alpha\mathbf{I}$  is added to the correlation matrix of LMS iteration. LMS iteration correlation matrix is  $\mathbf{R}_Y$  in leaky LMS this matrix is added  $\alpha$  times  $\mathbf{I}$  matrix is added.

We also note that  $\alpha\mathbf{I}$ , is the autocorrelation matrix of a white noise with variance  $\alpha$ . So if we have a white noise with variance  $\alpha$  then its autocorrelation function will be  $\alpha$  then rest of the elements in the first row will be 0 like that. Similarly second row this will be 0 then  $\alpha$  0 like that and finally the last row will be 0, 0, 0 and then last element will be  $\alpha$ .

So that way this will be the autocorrelation function of the white noise which is same as  $\alpha$  times  $\mathbf{I}$ . So, therefore the regularization process a white noise component is added to  $\mathbf{y}_n$  to the data a white noise component is added that way is pre whitening of data.

(Refer Slide Time: 09:03)

### Convergence condition for the Leaky LMS algorithm

❖ If  $\lambda_i$  is an eigen value of  $\mathbf{R}_y$ , then the corresponding eigen value of  $\mathbf{R}_y + \alpha \mathbf{I}$  will be  $\lambda_i + \alpha$ .

❖ For convergence, the constraint on  $\mu$  is

$$0 < \mu < \frac{2}{\lambda_{max} + \alpha}$$

Now let us examine the convergence condition for the leaky LMS algorithm. If  $\lambda_i$  is an eigen value of  $\mathbf{R}_y$  then the corresponding eigen value of  $\mathbf{R}_y + \alpha \mathbf{I}$  will be  $\lambda_i + \alpha$ . So if eigenvalue will be increase by  $\alpha$ . Therefore, for convergence the constraint on  $\mu$  is  $\mu$  should lie between 0 and  $2/\lambda_{max} + \alpha$ .

(Refer Slide Time: 09:39)

### Normalized LMS (NLMS) Algorithm

❖ Consider the LMS updating relation:

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \mu e(n) \mathbf{y}(n)$$

❖ For convergence of the LMS algorithm

$$0 < \mu < \frac{2}{\lambda_{max}}$$

and the conservative bound is given by

$$\begin{aligned} 0 < \mu &< \frac{2}{\text{Trace}(\mathbf{R}_y)} \\ &= \frac{2}{M \mathbf{R}_y(0)} \\ &= \frac{2}{MEY^2(n)} \end{aligned}$$

❖  $\mathbf{R}_y$  is not generally known. Thus,  $\lambda_{max}$  or  $\mathbf{R}_y(0)$  is to be estimated from data.

Next algorithm we will consider the normalize LMS NLMS algorithm. Consider the LMS update equation given by  $\mathbf{h}(n+1) = \mathbf{h}(n) + \mu e(n) \mathbf{y}(n)$  vector. For converge this  $\mu$  should be  $< 2 / \lambda_{max}$  and conservative bound for convergence is given by  $\mu < 2 / \text{Trace of } \mathbf{R}_y$  and that  $= 2/M$  times  $M$  is the number of filter coefficients  $M$  times  $\mathbf{R}_y(0)$  and  $\mathbf{R}_y(0)$  we can write it as expected value of  $E$  of  $Y^2(n)$ .

Therefore for convergent  $\mu$  should be  $< 2/M$  times  $E$  of  $Y^2$  square  $n$ . Note that  $RY$  is not generally known. Thus,  $\lambda_{\max}$  or  $RY$  of 0 is to be estimated from the data. This expression  $E$  of  $Y^2$  square  $n$  is to be estimated from data.

(Refer Slide Time: 11:03)

**NLMS algorithm**

- ❖ We can avoid this problem by using the estimate  $\frac{1}{M} \sum_{n=0}^M Y^2(n)$  of  $E(Y^2(n))$  and estimating the bound as

$$0 < \mu < \frac{2}{\sum_{i=0}^{M-1} Y^2(n-i)} = \frac{2}{\|y(n)\|^2}$$

- ❖ Now we can take

$$\mu = \beta \frac{1}{\|y(n)\|^2}$$

where  $0 < \beta < 2$

- ❖  $\beta$  is chosen to control the mis-adjustment factor.
- ❖ The convergence of the NLMS algorithm is faster irrespective of the choice of  $\beta$  in the above range.

We can avoid this problem by using the estimate  $1/M$  times summation  $Y^2$  square  $n$  going from 0 to  $M$  in place of  $E$  of  $Y^2$  square  $n$  and estimating the bound as  $0 < \mu < 2$  by this expression because  $M$  and  $1/M$  will get cancelled therefore  $0 < \mu < 2$  by summation  $y^2$  square  $n - i$ ,  $i$  going from 0 to  $M - 1$  and this is  $= 2/\text{norm of } y_n \text{ square}$ . Now we can take  $\mu$  because  $\mu < 2$  by norm of  $y_n$  square.

So we can take  $\mu = \beta \times 1 / \text{norm of } y_n \text{ square}$  where  $\beta$  is a number between 0 and 2. We can take any value of  $\beta$  between 0 to 2, but it is so then to control the mis adjustment factors small  $\beta$  value of  $\beta$  will give less misadjustment factor. The convergence of the NLMS algorithm is faster irrespective of the choice of  $\beta$  in the above range. If we choose  $\beta$  in this range the convergence of the NLMS algorithm will be faster than the corresponding speed of the LMS algorithm.

(Refer Slide Time: 12:47)

### NLMS algorithm

❖ The LMS updating becomes

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \beta \frac{1}{\|\mathbf{y}(n)\|^2} e(n) \mathbf{y}(n)$$

❖ Note that the multiplication by  $\frac{1}{\|\mathbf{y}(n)\|^2}$  changes the step size according to the variation in the signal magnitude, but it does not change the direction of estimated gradient given by  $\mathbf{y}(n)$

❖ If  $\mathbf{y}(n)$  is close to zero, the denominator term ( $\|\mathbf{y}(n)\|^2$ ) becomes very small and

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \beta \frac{1}{\|\mathbf{y}(n)\|^2} e(n) \mathbf{y}(n) \quad \text{may diverge}$$

❖ A parameter  $\gamma$  is included in the denominator to avoid large step sizes when  $\|\mathbf{y}(n)\|^2$  becomes close to zero:

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \beta \frac{1}{\gamma + \|\mathbf{y}(n)\|^2} e(n) \mathbf{y}(n)$$

Thus the LMS updating becomes  $\mathbf{h}(n+1) = \mathbf{h}(n) + \beta \times 1 / \text{norm of } \mathbf{y}(n) \text{ square} \times e(n) \text{ into } \mathbf{y}(n)$ . Note that multiplication by  $1 / \text{norm of } \mathbf{y}(n) \text{ square}$  changes the step size according to the variance of the signal magnitude, but it does not change the direction of the gradient given by  $\mathbf{y}(n)$  because  $\mathbf{y}(n)$  will specify the direction of the gradient this  $\mathbf{y}(n)$  is a vector and  $e(n)$  is a scalar.

Therefore  $\mathbf{y}(n)$  specifies the direction of gradient and multiplying by this factor will not change the direction of the gradient. If  $\mathbf{y}(n)$  is closed to zero then the denominator term let say norm of  $\mathbf{y}(n)$  square here becomes very small and in that case this expression  $\mathbf{h}(n) + \beta \times 1 / \text{norm of } \mathbf{y}(n) \text{ square} \times e(n) \text{ into } \mathbf{y}(n)$  may diverge because this term may blow up. A parameter gamma is included in the denominator to avoid large step size when norm of  $\mathbf{y}(n)$  square becomes close to zero.

So therefore ultimately  $\mathbf{h}(n+1)$  will be  $= \mathbf{h}(n) + \beta \times 1 / \gamma + \text{norm of } \mathbf{y}(n) \text{ square} \times e(n) \text{ into } \mathbf{y}(n) \text{ vector}$ . So this is the NLMS update rule.

**(Refer Slide Time: 14:47)**

### NLMS algorithm steps

❖ Given the input signal  $y(n)$ , desired signal  $d(n)$ , filter length  $M$

$\beta < 2$  and small constant  $\gamma$ .

1. Initialization  $h_i(0) = 0, i = 0, 1, \dots, M-1$

2. For  $n > 0$

Filter output  $\hat{d}(n) = \mathbf{h}'(n)\mathbf{y}(n)$

Estimation error  $e(n) = d(n) - \hat{d}(n)$

3. Filter coefficient adaptation

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \beta \frac{1}{\gamma + \|\mathbf{y}(n)\|^2} e(n) \mathbf{y}(n)$$

We can briefly state the NLMS algorithm so here given the input signal  $y_n$  desired signal  $d_n$ , filter length  $M$ ,  $\beta < 2$  and a small constant  $\gamma$ . Initialization  $h_i(0) = 0$  for  $i = 0$  to  $M - 1$  all filter coefficients are initialized to 0. For  $n > 0$  filter output will be  $\hat{d}(n) = \mathbf{h}^T(n) \mathbf{y}(n)$ . This is the filter output. Estimation error  $e(n) = d(n) - \hat{d}(n)$  and filter coefficient is updated according to this relationship NLMS update rule.  $\mathbf{h}(n+1) = \mathbf{h}(n) + \beta \frac{1}{\gamma + \|\mathbf{y}(n)\|^2} e(n) \mathbf{y}(n)$ .

**(Refer Slide Time: 16:00)**

### Example System identification:

You are given a 5-length FIR system with unknown parameters. Identify them.

❖ A white noise  $y(n)$  is input to both the system and adaptive filter. The output of the system is the desired signal  $d(n)$ .

❖ The 5-length adaptive filter is updated using the LMS and NLMS algorithm.

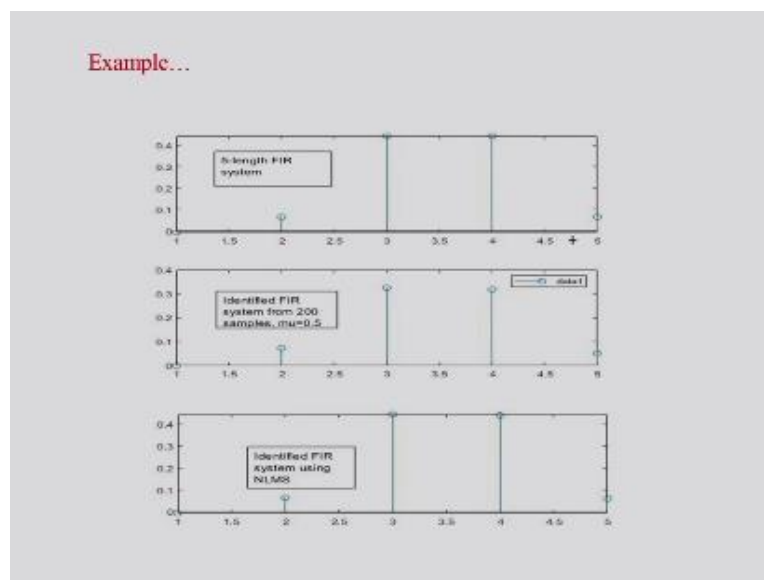

We will consider one example of system identification with the LMS and NLMS algorithm. System identification problem we introduced in the first class of adaptive filters. The problem is like this you are given a 5-length FIR system with unknown parameters identified them using adaptive filters. So here it is a 5-length FIR system we know that there are 5

coefficients in the FIR system model we have to identify those 5 parameters using a 5-length FIR adaptive filter.

So here  $y_n$  is the output to both the system and the adaptive filter and usually  $y_n$  should be a white noise and the desired signal  $d_n$  is the output of this unknown system and the adaptive filter will estimate this desired signal and this error signal is feedback to the LMS or NLMS update algorithm. So that way the 5-length adaptive filter is updated using the LMS and NLMS algorithm.

**(Refer Slide Time: 17:30)**

We show the simulation result so this is the original system 5-length FIR system these are the filter coefficient one coefficient is 0 here 0, this is the another coefficient third coefficient is like this, fourth coefficient is like this and fifth coefficient is like this and after identification by LMS algorithm with  $\mu = 0.5$  and data length is 200 we get this result. We see that this coefficient originally it was 0.44 like that here it is near 0.3.

So it is not exactly estimative. Similarly, this coefficient also it is not exactly estimating if we identify the FIR system using the NLMS algorithm we get the estimate results like this. Now this value and this value similarly this value and this value are almost matching. There is a small difference, but because it is 200 data only with that itself it is matching very well. Thus, we see that the NLMS algorithm converges faster than the LMS algorithm.

**(Refer Slide Time: 19:00)**

### Discussion -NLMS

- ❖ Under independence assumptions, it can be shown that the NLMS algorithm converges in the mean-square sense for  $0 < \beta < 2$
- ❖ The NLMS algorithm has more computational complexity compared to the LMS algorithm
- ❖ Note that

$$\begin{aligned}\|y(n)\|^2 &= \sum_{i=0}^{M-1} y^2(n-i) \\ &= \sum_{i=0}^{M-1} y^2(n-1-i) + y^2(n) - y^2(n-M+1) \\ &= \|y(n-1)\|^2 + y^2(n) - y^2(n-M+1)\end{aligned}$$

Thus,  $\|y(n)\|^2$  can be efficiently estimated using the recursive relation

Let us quickly discuss the merits of the NLMS algorithm under the independent assumption it can be shown that the NLMS algorithm converges in the mean square sense provided beta lies between 0 and 2. The NLMS algorithm has more computational complexity compared to the LMS algorithm because of the computation of norm at every instance. Note that norm of  $y_n$  square = summation  $y$  square  $n - i$   $i$  going from 0 to  $M - 1$ .

This summation we can rewrite as summation  $i$  going from 0 to  $M - 1$   $y$  square  $n - 1 - i$ . We are considering the earlier instances starting from  $n - 1$  then we have to add  $y$  square  $n$  because here  $n - 1$ ,  $i$  going from 0 so first term will be  $y$  square  $n - 1$  so  $y$  square  $n$  we have to include. Similarly that last term here will be  $y$  square  $n - M + 1$  and therefore this term should be subtracted.

Therefore, this norm of  $y_n$  square can be written as norm of  $y_{n-1}$  vector square +  $y$  square +  $y$  square and -  $y$  square  $n - M + 1$ . So that way norm of  $y_n$  square can be estimated recursively only this part we have to calculate this part and this part and then add to earlier estimate of norm square.

**(Refer Slide Time: 20:58)**

### Discussion – LMS ...

- ❖ If  $\mathbf{y}(n)$  is close to zero, the denominator term ( $\|\mathbf{y}(n)\|^2$ ) in NLMS equation becomes very small and

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \beta \frac{1}{\|\mathbf{y}(n)\|^2} e(n) \mathbf{y}(n) \quad \text{may diverge}$$

- ❖ To overcome this drawback a small positive number  $\varepsilon$  is added to the denominator term the NLMS equation. Thus

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \beta \frac{1}{\varepsilon + \|\mathbf{y}(n)\|^2} e(n) \mathbf{y}(n)$$

If  $\mathbf{y}_n$  is close to zero the denominator term norm of  $\mathbf{y}_n$  square in NLMS equation becomes very small and this term  $\mathbf{h}_{n+1} = \mathbf{h}_n + \beta \text{ times } 1/\text{norm of } \mathbf{y}_n \text{ square into } e_n \text{ into } \mathbf{y}_n \text{ vector}$  may diverge. To overcome this drawback a small positive number epsilon is added in the denominator term of the NLMS update equation. Thus  $\mathbf{h}_{n+1} = \mathbf{h}_n + \beta \text{ times } 1/(\text{epsilon} + \text{norm } \mathbf{y}_n \text{ square into } e_n \text{ into } \mathbf{y}_n \text{ vector})$ . This is the modified NLMS update rule.

(Refer Slide Time: 21:54)

### LMS algorithm with reduced complexity

- ❖ In many applications like high speed communication, faster adaptation processes is needed.
- ❖ For such applications, computational efficiency is very important. For this purpose, modifications are suggested to the LMS algorithm.
- ❖ A number of modifications are available. Some of these include *block LMS* algorithm, *signed error LMS* algorithm, *signed data LMS* algorithm, *signed-sign LMS* algorithm etc.
- ❖ We will briefly outline the block-LMS algorithm and the signed error LMS algorithm

Now we will discuss some LMS based algorithms with reduced complexity. In many applications like high speed digital communication, faster adaptation is needed. For such applications computational efficiency is very important for this purpose modifications are suggested to the LMS algorithm. A number of modifications are available. Some of these include block LMS algorithm sign LMS algorithm, signed data LMS algorithm, sign-sign

LMS algorithm etcetera. We will briefly outline the block LMS algorithm and this signed error LMS algorithm.

(Refer Slide Time: 22:53)

### Block LMS algorithm

❖ In block LMS algorithm, the input signal is divided into blocks of length  $L$  each.

❖ The filtering output for the  $k$ th block is

$$\hat{d}(kL+i) = \mathbf{h}^T(k) \mathbf{y}(kL+i), \quad i = 0, 1, \dots, L-1$$

The filtering operation is efficiently performed by using the FFT.

❖ The error is estimated as

$$e(kL+i) = d(kL+i) - \hat{d}(kL+i), \quad i = 0, 1, \dots, L-1$$

❖ Now filter weights are updated block-wise.

$$\mathbf{h}(k+1) = \mathbf{h}(k) + \mu \frac{1}{L} \sum_{i=0}^{L-1} e(kL+i) \mathbf{y}(kL+i), \quad k = 0, 1, \dots$$

❖ Block LMS algorithm has the same convergence characteristics as the LMS algorithm with a larger excess mean-square error.

First we will see the block LMS algorithm. In block LMS algorithm the input signal is divided into blocks of length  $L$  each. So processing will be done in a block of  $L$  inputs. The filtering output for the  $k$ th block is given by this  $\hat{d}(kL+i) = \mathbf{h}^T(k) \mathbf{y}(kL+i)$  this is the vector data vector  $i$  going from 0, 1 upto  $L-1$ . So that way we will be considering suppose this is fixed now.

But for different data in this block that is  $kL+0$   $kL+1$  etcetera those data vector we will be considering and filtering. Now this is the filtering operation since  $\mathbf{h}(k)$  is fixed now because in one block only one filter coefficient vector will be used. Therefore the filtering operation is efficiently performed by using FFT. So you can use FFT to perform this. The error is estimated as  $e(kL+i) = d(kL+i) - \hat{d}(kL+i)$   $i$  going from 0, 1 upto  $L-1$  this is the filtering error.

Now the filter weights are updated block-wise according to this updating rule  $\mathbf{h}(k+1)$  vector that  $= \mathbf{h}(k) + \mu \frac{1}{L} \sum_{i=0}^{L-1} e(kL+i) \mathbf{y}(kL+i)$  vector  $i$  going from 0 to  $L-1$  this is done for each data point in the block. So that way here we see that the error into the data vector these are summed up and then divided by  $L$  to get the estimate for the error into the data vector.

So this is the block LMS update in rule. Block LMS algorithm has the same convergence characteristics as the LMS algorithm with a larger excess mean square error. It can be shown that each excess mean square error is larger.

(Refer Slide Time: 25:49)

**Sign-error LMS algorithm**

- ❖ Consider the LMS update rule  

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \mu e(n) \mathbf{y}(n)$$
- Note that, the estimated gradient direction is given by  $\mathbf{y}(n)$  and multiplication by  $e(n)$  does not change this direction, except when  $e(n)$  changes sign.
- ❖ For faster updating,  

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \mu \text{sgn}(e(n)) \mathbf{y}(n)$$
 where
 
$$\text{sgn}(e(n)) = \begin{cases} 1; & e(n) > 0 \\ 0; & e(n) = 0 \\ -1; & e(n) < 0 \end{cases}$$
- ❖ The signed-error algorithm can be derived using  $|e(n)|$  in place of the LMS cost function  $e^2(n)$ .
- ❖ The signed LMS algorithm is equivalent to the LMS algorithm with 2-bit quantization of the error. Therefore, the convergence is poorer in the case of this algorithm.

Next algorithm is sign-error LMS algorithm. Consider the LMS update rule  $\mathbf{h}(n+1) = \mathbf{h}(n) + \mu e(n) \mathbf{y}(n)$  vector so this is the LMS update rule  $\mathbf{h}(n+1) = \mathbf{h}(n) + \mu \text{sgn}(e(n)) \mathbf{y}(n)$ . Note that the estimated gradient direction is given by  $\mathbf{y}(n)$  this is the vector this vector gives the estimated gradient direction and multiplication by  $e(n)$  does not change this direction except when  $e(n)$  changes sign.

So if  $e(n)$  is negative this direction will become negative so that way only that rule is performed by  $e(n)$ . Therefore, for faster updating  $\mathbf{h}(n+1) = \mathbf{h}(n) + \mu \text{sgn}(e(n)) \mathbf{y}(n)$ . So where  $\text{sgn}(e(n)) = 1$  if  $e(n) > 0$ ,  $0$  if  $e(n) = 0$  and  $-1$  if  $e(n) < 0$ . This signed-error algorithm can be derived using  $|e(n)|$  in place of this LMS cost function  $e^2(n)$ . If we use  $|e(n)|$  in place of  $e^2(n)$  then by applying the (27:28) we can derive this updating rule.

So that way it necessarily follows from this cost function  $|e(n)|$  cost function absolute error cost function. The signed LMS algorithm is equivalent to the LMS algorithm with 2-bit quantization. So we have 3 values of error that is 1, 0 and -1 so that way it is 2-bit quantization. Therefore, the convergence is poorer in the case of this algorithm because instead of using the entire error we are using it in 3 values only.

### Summary

- ❖ The cost function of the leaky LMS (LLMS) algorithm includes a regularization term resulting in the problem

$$\text{Minimize } e^2(n) + \alpha \|\mathbf{h}(n)\|^2$$

- ❖ The term  $\alpha \|\mathbf{h}(n)\|^2$  ensures that  $\mathbf{h}(n)$  converges faster.

- ❖ The LLMS update equation is given by

$$\mathbf{h}(n+1) = (1 - \mu\alpha)\mathbf{h}(n) + \mu\alpha e(n)\mathbf{y}(n)$$

- ❖ The normalized LMS (NLMS) algorithm uses a variable step size given by

$$\mu = \beta \frac{1}{\|\mathbf{y}(n)\|^2}, \quad 0 < \beta < 2$$

- ❖ To ensure convergence when  $\|\mathbf{y}(n)\|^2$  is small, NLMS updating is modified as

$$\mathbf{h}(n+1) = \mathbf{h}(n) + \beta \frac{1}{\epsilon_0 + \|\mathbf{y}(n)\|^2} e(n)\mathbf{y}(n)$$

Let us summarize the lecture. The cost function of the leaky LMS, LLMS algorithm includes a regularization term resulting in the problem that is minimize  $e^2(n) + \alpha \|\mathbf{h}(n)\|^2$  where  $\alpha$  is a constant. The term  $\alpha \|\mathbf{h}(n)\|^2$  ensures that  $\mathbf{h}(n)$  converges faster. So, because of this regularizing term. So this is the regularizing term it ensures that there is no mass deviation between two iterations.

The LLMS update equation is given by  $\mathbf{h}(n+1) = (1 - \mu\alpha)\mathbf{h}(n) + \mu\alpha e(n)\mathbf{y}(n)$ . So this is the update equation for LLMS algorithm. The normalized LMS NLMS algorithm uses a variable step size given this relationship  $\mu = \beta / \|\mathbf{y}(n)\|^2$  where  $\beta$  lies between 0 and 2. To ensure convergence when norm of  $\mathbf{y}(n)$  square is small because if  $\mathbf{y}(n)$  become very small then this quantity will become small and this will diverge.

Therefore, to ensure convergence when norm of  $\mathbf{y}(n)$  square is small NLMS updating is modified as  $\mathbf{h}(n+1) = \mathbf{h}(n) + \beta \frac{1}{\epsilon_0 + \|\mathbf{y}(n)\|^2} e(n)\mathbf{y}(n)$ . So this  $\epsilon_0$  is a small positive constant which ensures that there is no divergence.

## Summary

- ❖ For some applications, computational efficiency is very important. For this purpose, modifications are suggested to the LMS algorithm.
- ❖ The *block LMS* algorithm and *signed error LMS* algorithm are efficient for hardware implementation.

For some applications computational efficiency is very important. For this purpose modifications are suggested to LMS algorithm (()) (30:45) modifications are block LMS algorithm and signed error LMS algorithm are efficient for hardware implementation. We knew that block LMS the filter coefficient are updated after a block of data. In signed-error LMS algorithm instead of  $e(n)$   $\text{sign}\{e(n)\}$  is used in the LMS updating equation.

So we have discussed about LMS algorithm. Next we will discuss another approach to adaptive filtering that is Recursive Least Square Algorithm. Thank you.
