Dielectric Waveguide

So strategy seems to be alright okay. Everything seems to be fine. We just need to start with Wave equation for Hz. But we already know what the wave equation for Hz right.

(Refer Time Slide: 00:24)

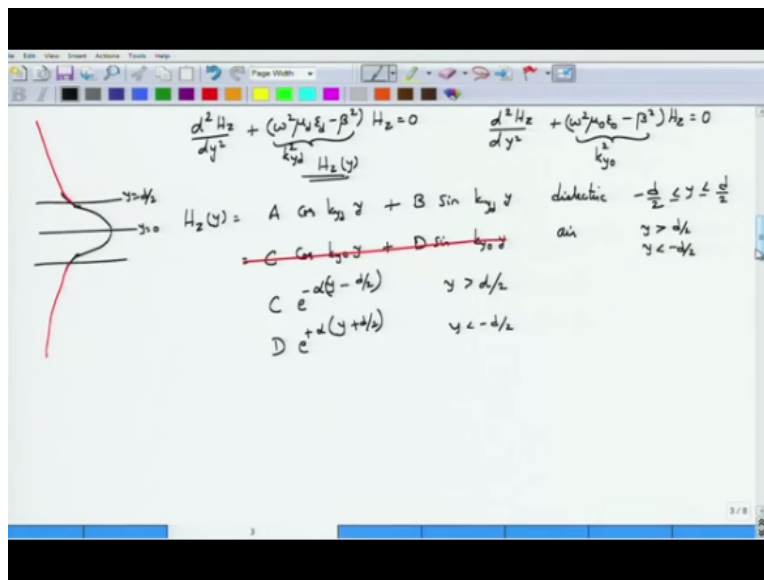

What is the wave equation for Hz? I have del square H z minus omega square mu d epsilon d, this d stands for dielectric okay, times Hz must be equal to 0. This of course, works only in the dielectric film region or dielectric region in this particular case. The same equation will hold, except you replace this mu d and epsilon d by mu 0 and epsilon 0 for the case of, this must be plus. So this is plus, for the case of outside the dielectric region okay. So these are my equations.

From them, I will have to write down, I mean, I have to solve Hz okay. Del square of course consists of del square by del x square plus del square by del y square plus del square by del z square. I have no dependence on x, therefore the first one vanishes. I do not know the dependence on why therefore the second term remains. I know the dependence on del square by del z square, which is basically minus beta square right. So this is what I have.

So, this is minus beta square and you can substitute this into the expression to obtain H_z both in the dielectric and outside the dielectric region and because there is only one dependence on y , I can change this partial derivative of del by del y into the total derivative d by d y . I have $d^2 H_z$ by $d y$ square plus $\omega^2 \mu_0 \epsilon_0 \epsilon_r - \beta^2$ into H_z equal to 0. This is for the dielectric region.

The same equation will be $d^2 H_z$ by $d y$ square plus $\omega^2 \mu_0 \epsilon_0 - \beta^2$ times H_z is equal to 0. In these equations, H_z is a function of y .

(Refer Time Slide: 02:32)

We can have a short hand notation, so call this $\omega^2 \mu_0 \epsilon_0 \epsilon_r - \beta^2$ as k_y^2 , and call this $\omega^2 \mu_0 \epsilon_0 - \beta^2$ as k_{y0}^2 , that 0 stands for outside the dielectric region. Now, how do I solve these equations? Well, these are second order ordinary differential equations. The solution for these equations is also known. H_z of y will be some $A \cos k_y y$ or it could be $\sin k_y y$. Now, this is for the dielectric region correct.

And for the A region or outside the dielectric, the same equation will be some $C \cos k_{y0} y$, sorry I made a small mistake here, so it must be $k_{y0} y$, not d coming in the numerator, it is just the subscript for $k_{y0} \sin k_{y0} y$. this is for the solution in air. So, we have this solutions, of course the dielectric region goes from minus $d/2$ less than or equal to y less than or equal to $d/2$

by 2. This would be y greater than d by 2 or y less than minus d by 2 right. So these are the dielectric and air regions that we have written down over here.

I have now four unknowns A, B, C, D . I will have to apply boundary conditions to match them and see whether I am actually able to get anything over here. Now, before we proceed, let us actually understand whether these equations, the way we have written down are reasonably alright or not okay. If you look at the top one, you wanted a propagating kind of a solution right. So you wanted a $\cos k_y y$ and a $\sin k_y y$ type of a solution.

However, in the air region, we seem to have made a mistake. What is the mistake that we have made? We do not want a wave which is propagating along y . In fact, what we want is a wave which is decaying along y right. So, if you graphically look at this, $\cos k_y y$ assuming that, that is what I am looking at. So if this is my y equal to 0 axis. So, $\cos k_y y$ would be a wave which would go like that. If it was a metallic wall, it would have gone down to 0 at both ends.

But, since this is not a metallic wall, there would be a small penetration of the wave here, outside the dielectric region. Now, once outside you are there, you do not want further, you know a \sin or a \cos kind of a solution. Although in some cases you will not have any control and then you will have to accept this propagating solution or sometimes you desire this okay. In cases, where you want to couple light from one wave guide to another wave guide, you want a cosine kind of situation right, outside the dielectric region of the first wave guide as well.

But, that is not our intention, we are not coupling anything from one to another. So for us, this inside the dielectric is perfectly fine, but outside the dielectric, we want the wave to basically decay to 0 okay. So, we want the wave to essentially go down to 0 outside the dielectric region. Which means that, I cannot choose them to be propagating type of solutions, rather I have to choose them to be decaying kind of solution.

So, the solution here in the region above y equal to d by 2, we can choose this as C exponential, we want them to be decaying exponentially and that would happen when β^2 is actually greater than $\omega^2 \mu_0 \epsilon_0$. But when β is less than $\omega \sqrt{\mu_0 \epsilon_0 d}$

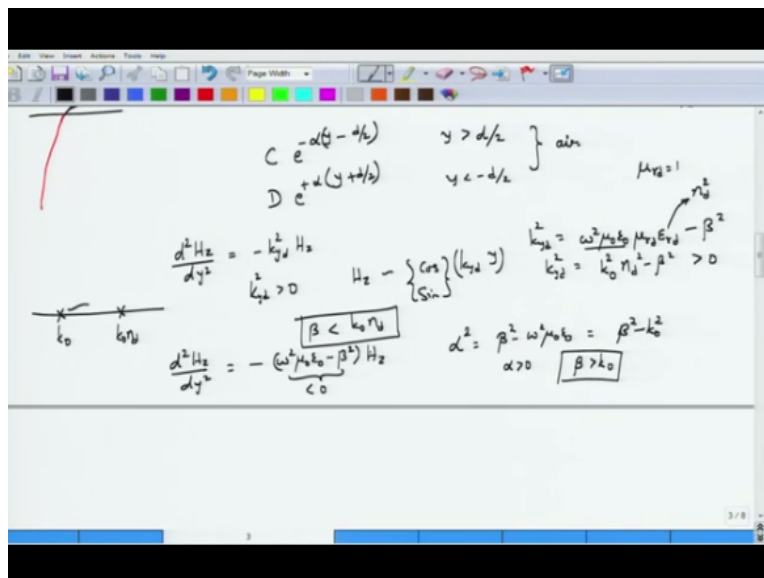

d, then you will have the propagation inside and decay outside, we will see that one in a moment. So $C e^{-\alpha(y-d/2)}$, call this as alpha and y okay.

So, I just need a decaying solution, I do not want an expanding solution, therefore, I will take this as minus alpha y. But I know that, at this point I do not want the expression for the decaying wave to be equal to C, you know I want this value to be valid at d by 2. So I just shift the origin from y equal to 0 to y equal to d by 2 and call this as e to the power minus alpha y minus d by 2, which would be valid for the region above the dielectric.

Why because, you put this y equal to d by 2, you get this expression, exponential will be one and the value here will be equal to C okay. Similarly, for y less than minus d by 2, I shift the origin okay, I take this as e power plus alpha because, now the value of y is negative. So, I take this as y plus d by 2 okay. So, now I have complete solutions for H_z , except for the constants C and D, which I will now have to evaluate by applying boundary condition.

These two are the solutions in air, one above the dielectric, one below the dielectric. This is the solution inside the dielectric region. Let us write down also what is this alpha.

(Refer Time Slide: 07:38)

See, I have this $d^2 H_z / dy^2$, the way I would solve this second order partial differential equation would be to push this $k y^2$ outside. So, I will have minus $k y^2$

d Hz right. As long as $k_y d$ is greater than 0 or $k_y d$ square is greater than 0, the solution of this one will be Hz as \cos of $k_y d$ or \sin of $k_y d$ okay. So, this would be the solution of Hz, as long as $k_y d$ square is greater than 0.

But, what is $k_y d$? $k_y d$ is nothing but $\omega^2 \mu_0 \epsilon_0 \mu_r d \epsilon_r$ right minus β^2 . This is my $k_y d$ square, the propagation constant inside the dielectric region. But, I can write down this $\mu^2 \mu_0 \epsilon_0$ as some k_0^2 inside air. This is the same thing that would be there in the air as well. So, I can as well have a short hand notation for this, and if I assume that $\mu_r d$ is equal to one okay.

That is, the dielectric medium does not, is in fact non magnetic, then I can eliminate this $\mu_r d$ from the discussion and I also know that $\epsilon_r d$ would be the refractive index of the dielectric region. Therefore, I can consider this as $n^2 d$ okay, n^2 standing for refractive index of the medium okay. So, I have $k_0^2 n^2 d$ minus β^2 . This is your propagation constant $k_y d$ inside the dielectric region and this has to be greater than 0, which means that β must be less than $k_0 n^2 d$, this is the first condition.

Now, to the same equation outside the dielectric, let us say above the dielectric, this should be equal to minus $\omega^2 \mu_0 \epsilon_0$ minus β^2 times Hz. Again, if $\omega^2 \mu_0 \epsilon_0$ which can be written as k_0^2 is greater than β^2 . The solution will be of the form of \cos and \sin , which is what I do not want. So, what I really want is that this k_0^2 , this fellow should actually be less than 0 right.

So, if this is less than 0, then this would be negative okay, so that, I can have a exponential solution, then I will have, actual solution will be in the form of β^2 minus $\omega^2 \mu_0 \epsilon_0$ times Hz and then that would be the solution. So, what I will do is, I will define α^2 as β^2 minus $\omega^2 \mu_0 \epsilon_0$ or β^2 minus k_0^2 okay. So, if this is my α or rather we can define α as minus β^2 minus k_0^2 .

So, if I define this way, then this is k_0^2 minus β^2 , so, this would actually be minus α^2 . So everything is alright. So, if I define α^2 as β^2 minus k_0^2

square and then demand that alpha should be a positive quantity, the way it can happen is, when beta is greater than k_0 . So, I have two conditions for propagation, that beta must be greater than 0, but beta must be less than $k_0 n_d$.

So, if I were to plot the numbers, this is where the lower limit for beta would arise, that would be k_0 . This would be the higher limit $k_0 n_d$ and somewhere here, will be the value of beta. You can actually combine these two equations and eliminate beta, but then you will be expressing everything in terms of alpha okay. So, we now have the solutions for H_z , we know where the solutions would be and how the solutions formats are, and all that we are going to do with boundary condition is to stitch them together at this point okay.

So, we apply boundary condition to stitch them together. What sort of boundary condition should we apply? Can I apply or you know tangential H_z is going to 0 at the two boundaries. Unfortunately, I cannot, this is a dielectric and a dielectric boundary right. Well in this particular case I can, but if you go to e_z I will not be able to do so. So, I can actually try and apply the continuity condition.

Moreover, the form of the solution indicates that, this itself can be split up in to two types, one is $\cos k_y d$ and the other is $\sin k_y d$ of y .

(Refer Time Slide: 12:08)

The image contains the following handwritten content:

- Dielectric Region ($-\frac{d}{2} \leq y \leq \frac{d}{2}$):**

$$\frac{d^2 H_z}{dy^2} + (\omega^2 \mu_0 \epsilon_d - \beta^2) H_z = 0$$

$$H_z(y) = A \cos k_{y2} y + B \sin k_{y2} y$$

Symmetric even (pointing to the cosine term)
- Air Region ($y > d/2$ and $y < -d/2$):**

$$\frac{d^2 H_z}{dy^2} + (\omega^2 \mu_0 \epsilon_0 - \beta^2) H_z = 0$$

$$C e^{-\alpha(y-d/2)} \quad y > d/2$$

$$D e^{+\alpha(y+d/2)} \quad y < -d/2$$
- Boundary Conditions:**
 - At $y = \pm d/2$, H_z is continuous.
 - The derivative of H_z is discontinuous due to surface currents.
- Wave Numbers and Dispersion Relations:**
 - $k_{y2}^2 = \omega^2 \mu_0 \epsilon_d \mu_r \epsilon_r - \beta^2$
 - $k_{y1}^2 = \omega^2 \mu_0 \epsilon_0 \mu_r \epsilon_r - \beta^2$
 - Condition for propagation: $k_{y2}^2 > 0$
 - Condition for evanescent waves: $k_{y1}^2 < 0 \Rightarrow \alpha > 0$
 - Relationships: $\beta < k_0 n_d$ and $\beta > k_0$
- Diagram:** A sketch of a dielectric slab of thickness d centered at $y=0$. The dielectric constant is ϵ_d and the air region has ϵ_0 . Magnetic field lines H_z are shown as loops within the slab and decaying in the air.

This cos will be a symmetric wave guide with respect to the center okay. So, this would be symmetric or we can call this a s even mode, because the mode shape is essentially even okay. For the odd mode, which would be in the form of a sin wave right. So, it would be a sin, which means that, if this is my axis, then this should be a sin, so it should actually go something like this.

So, this is how the sin wave should look and they are actually odd, in the sense that, at the y equal to 0 plane, they actually carry opposite signs, whereas the cos will have the same sign and therefore that would look like a symmetric or even wave form. So, let us look at odd wave forms first okay. So, which means that my solution inside the dielectric will be of the form of sin.

(Refer Time Slide: 13:06)

Handwritten mathematical derivations on a whiteboard:

$$E_x(y) = -\frac{j\omega\mu_0}{k_y d} H_0 \cos k_y y \quad -\frac{j\omega\mu_0}{\alpha} H_0 \sin\left(\frac{k_y d}{2}\right) e^{-\alpha(y-d/2)}$$

$$H_y(y) = -\frac{j\beta}{k_y} H_0 \cos k_y y \quad -\frac{j\beta}{\alpha} H_0 \sin\left(\frac{k_y d}{2}\right) e^{-\alpha(y-d/2)}$$

Boundary conditions (B.C):

$$H_0 \sin k_y y \Big|_{y=d/2} = C$$

$$C = H_0 \sin\left(\frac{k_y d}{2}\right)$$

$$H_0 \sin k_y y \Big|_{y=-d/2} = D$$

$$-H_0 \sin\left(\frac{k_y d}{2}\right) = D$$

So, I can write down H_z y for the odd, odd TE case. I will leave the even TE case as an exercise for you. So for the odd TE case, H_z of y is equal to $B \sin k y d$. Rather than calling this as B, let us simply call this as H_0 , that 0 nicely indicating that this is an odd TE mode that we are considering. So you have $H_0 \sin k y d y$, for this one, solution is valid for y less than mode by less than d by 2 that is inside the film.

We can also find out what are the x and y components for this particular mode. So E_x of y will be equal to minus j omega mu 0 divided by k y or k y d times $H_0 \cos k y y$ okay, after applying the boundary conditions and then appropriately differentiating this H_z because E_x will be

proportional to $\frac{\partial H_z}{\partial x}$ multiplied by some constants over here. Similarly, you can show that H_y of y will be equal to $-\frac{j\beta}{k_y d} H_0 \cos k_y y$ okay.

So, these are the solutions for E_x and H_y . We also know the solutions for H_z . Now, we can actually apply the appropriate boundary conditions. We can write the equations for air region as well. So, first consider $y > \frac{d}{2}$ for which E_x of y becomes $-\frac{j\omega\mu_0}{\alpha} e^{-\alpha(y - \frac{d}{2})}$ but, the differential of H_z , H_z is now $e^{-\alpha(y - \frac{d}{2})}$. Therefore, it would be α that is coming out in the denominator. So, that would be $\alpha H_0 \sin k_y \frac{d}{2}$.

That would be at the boundary the continuity condition $e^{-\alpha(y - \frac{d}{2})}$ ok and then, you will also have the solution for H_y , which is $-\frac{j\beta}{\alpha} H_0 \sin k_y \frac{d}{2} e^{-\alpha(y - \frac{d}{2})}$. If you are slightly confused at this point we can actually go back and apply the boundary condition. I assume that you could apply the boundary condition very nicely. So, let us write down this as $H_0 \sin$. So, this is how you apply the boundary condition.

I am going to just motivate the boundary condition to you. I will not go into details for this one okay. So, this is $H_0 \sin k_y \frac{d}{2}$ this was the solution as you would be there in the dielectric region. This at $y = \frac{d}{2}$, must be equal to the condition for the wave at air right. So, at $y = \frac{d}{2}$, if you approach from the top, the solution would be in the form of $C e^{-\alpha(y - \frac{d}{2})}$. Therefore, at $y = \frac{d}{2}$, this would be equal to C .

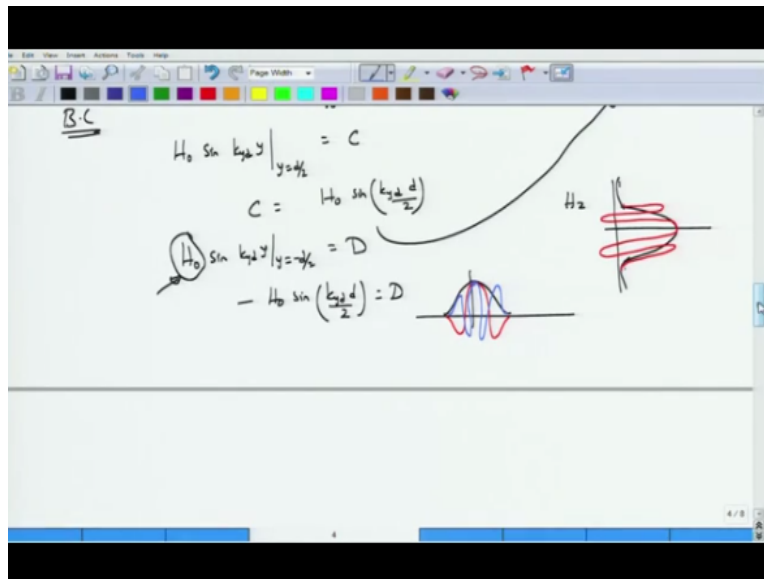

So, this would be equal to C , so, C is equal to $H_0 \sin k_y \frac{d}{2}$ and this is precisely what this factor is coming in over here okay. So, this is the boundary condition and this is the amplitude of the wave outside the dielectric region. Similarly, you have $H_0 \sin k_y \frac{d}{2}$ at $y = \frac{d}{2}$ must be equal to H_0 , which is the amplitude at $y = \frac{d}{2}$ right. So, $y = \frac{d}{2}$.

But if you substitute for this, \sin becomes \sin of $k_y \frac{d}{2}$ into $-\frac{j\beta}{\alpha} H_0 \sin k_y \frac{d}{2} e^{-\alpha(y - \frac{d}{2})}$ is equal to D ok and this is precisely what you get. If you were to write down the expressions again for the region $y \leq -\frac{d}{2}$ okay. So, once we have

determined everything and you can now clearly understand where H_0 must be coming from? H_0 comes from the total power normalization. What is the power that is actually carried by the wave and that integral will tell you how to fix the value of H_0 .

So, we have figured out everything, we know how H_z looks like, we know how E_x looks like, you know how H_y looks like okay.

(Refer Time Slide: 17:22)

We know that H_z has a function of y is a cosine wave and depending on the order, so you can have m is equal to, the solutions will be of the form of a different orders right. Because you have a $\cos k y d$ by 2 and you can approach the same value in two different waves. So, you can approach it by one half cycle, you can approach it by two half cycles okay. So, let me try to draw two half cycles over here and this is how the wave would decay outside okay.

So, I need to approach it with a different or two half cycles, so let me try that. This is the second $\cos k y d$ by 2 or rather if you are able to plot it in this way, this is my fundamental mode, the next mode will be this one right. So, it would actually approach in this way. So, this is the next mode and now I can draw the higher order modes if you want. This is the next higher order mode again as I said the drawing is slightly confusing for me.

But, these different modes correspond to the different orders. Again, there is no specific greatness about this mode orders. They are just indicated the possible solutions as the different mode shapes contained by the electric and magnetic field combined. They are just come in different flavors in which a sustainable E and H patterns for the particular solution would exist. So, these are called as modes. Let me close this discussion on dielectric wave guides.

I mean, I have not written down the expressions here for y less than minus d by 2, I will leave that as an exercise for you okay. So, you write down the expressions for y less than minus d by 2. The solution for even TE would not change okay. Sorry I wrote down the expressions as even TE but I was talking in terms of odd TE. So, for the solutions for even TE there is no problem, instead of $\sin k y d y$, you will write down this as $\cos k y$ and then you would simply continue applying the appropriate boundary condition.

The crucial point here is that, Hz was not equal to 0 but then, the tangential Hz was simply continuous. You do the analysis for Tm waves and I will leave that as an exercise for you.

(Refer Time Slide: 19:52)

Handwritten notes on a whiteboard showing the derivation of cut-off frequencies for TE modes in a dielectric waveguide. The notes include the following equations and relationships:

- Cut-off frequencies**
- Transcendental equation: $\frac{\alpha}{k_{yd}} = \tan\left(\frac{k_{yd}d}{2}\right) \leftarrow \text{BC}$
- Wave numbers: $k_{yd}^2 = k_0^2 n_1^2 - \beta^2$ and $\alpha^2 = \beta^2 - k_0^2$
- Relationship: $\alpha^2 + k_{yd}^2 = k_0^2 n_1^2 - k_1^2 = \frac{k_0^2}{n_2^2} (n_1^2 - 1)$
- Expression for alpha: $\alpha = \sqrt{k_0^2 (n_1^2 - 1) - k_{yd}^2}$
- Boundary condition: $C e^{-\alpha(y-d/2)} \quad y > d/2$
- Condition for cut-off: $\alpha \rightarrow 0 \Rightarrow \text{modes are cut-off}$
- Condition for propagation: $\beta \rightarrow k_0$
- Equation for cut-off: $\tan\left(\frac{k_{yd}d}{2}\right) = m\pi = (n-1)\pi \quad n=1, 2, 3, \dots$
- Final equation for cut-off frequency: $\tan\left(\frac{\omega_c \sqrt{n_1^2 - 1} d}{2}\right) = (n-1)\pi$

Let us discuss one aspect which is cut of frequencies for these modes. So, how do we define the cut off frequencies? Well, when does we have the propagation right. So, you start with alpha, you also know what is k y d right. So, alpha is basically given by writing down the boundary

condition, you will be able to express the relationship between α and $k_y d$, because I have, in one case I have $H_0 \sin k_y d$ and the other one will be $a \cos k_y d$.

So, the ratio of α to k_y can be written down as α by $k_y d$ is equal to $\tan k_y d$. So, $\tan k_y d$, this can be obtained again from the boundary condition. This relationship tells you the different values of $k_y d$ and α , how do you choose them? Of course, solving this equation is kind of very difficult because, $k_y d$ is present on both left hand side as well as on the right hand side. These equations are known as transcendental equation and the solution of this has to be done by a numerical analysis.

We will not go into those details in this particular case okay. So, you can obtain this equation as I said from the boundary conditions, we will not pursue this one, but you can actually add α and α^2 and $k_y^2 d^2$ okay. So, I know what is $k_y^2 d^2$. $k_y^2 d^2$ is nothing but $k_0^2 n^2 d^2 - \beta^2$. I also know what is α^2 . α^2 is nothing but, $\beta^2 - k_0^2$.

So, if I add these 2 together, I get $\alpha^2 + k_y^2 d^2$ equal to $k_0^2 n^2 d^2 - \beta^2$ or taking k_0^2 as a common factor, I get $n^2 d^2 - 1$ okay. Now, I can express what α is? α in terms of $k_y d$, that would be equal to $k_0^2 n^2 d^2 - 1 - k_y^2 d^2$. Remember, whenever you have $k_y d$ value, which is non 0 there will be a mode which is propagating okay. So, this is your expression for α .

What would happen to the phase constant β right? See, as α goes to 0, β would simply approach k_0 , that is from this expression very clear right. So, if α goes to 0, the way it can go to 0 is when β approaches k_0 . So, for a given k_0 , α will go to 0, because β is approaching k_0 . So with that, let us actually, so, when that happens with α is equal to 0, the waves are no longer cut off right.

The waves are no longer bound to the dielectric region, and therefore the waves are cut off in the sense that they would not be confined inside the wave guide. Why? Because if the wave, if α goes to 0, then α times y minus d by 2 was the solution outside the dielectric region at the air

for y greater than $d/2$, but with α going to 0, the solution would not decay, but rather it would remain a constant.

There was a $C e^{-\alpha y}$ and we also saw how to obtain C , but the point is that, as α goes to 0, the $C e^{-\alpha y}$ does not go to 0 as you increase y , rather it remains fixed at a given value of C and therefore energy is carried away from the mode outside the air region. Similarly, if you go to the bottom surface or the substrate region, you can see the same condition. So, α going to 0 implies modes are being cut off okay.

So, this is the situation, where the waves are cutting off and the solution for that would be to look at, since I know the relationship between α and $k y d$ as α goes to 0, the solution can only happen when $k y d/2$ would go to 0 or you know the integer multiples right. So, this should go to either 0 for \tan to go to 0 or it should go to, I will just write down this as multiple of π m standing for different orders right.

So, with m is equal to 0, 1, 2 or 3 you will have different modes coming in, if you want you can replace $m \pi$ by $n - 1$ into π and set n is equal to 1, 2 and 3 and so on. This is sometimes used. This m notation or n notation is used in literature both are used. So, either you, the first mode will be TE 0 mode or TE 1 mode. TE 1 mode would indicate a half cycle, TE 0 mode would indicate no minima in the region okay.

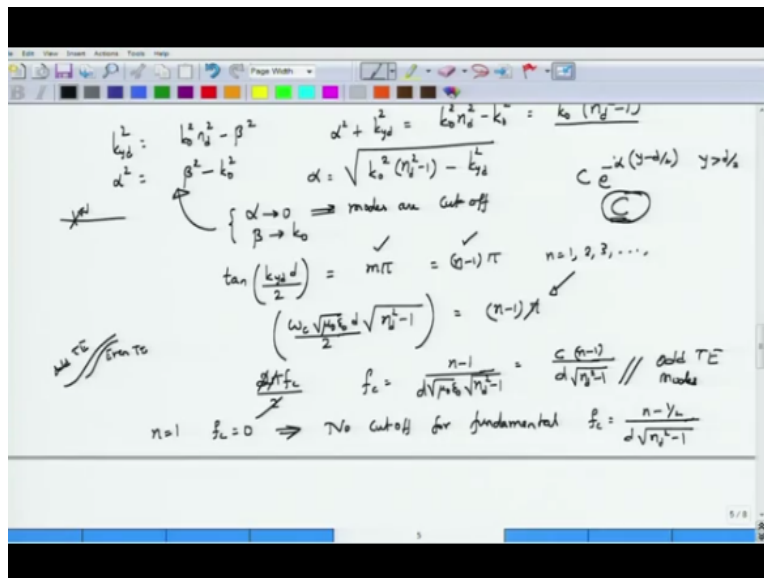

So, these are just kind of two different notations but the essential idea is that, these mode designations actually follow because they are getting multiples of π and making this \tan of this expression equal to 0 okay. But I know what is $k y d$ right. I know what is $k y d$, I can write down the condition at which this happens by specifically writing this as $\omega c d/2 \sqrt{\epsilon_r d}$, which would be the expression for this one, minus 1.

Why minus 1? Because ϵ_r of air is equal to 1 and this $\epsilon_r d$ under root is nothing but $n d$ square okay. So, this is the condition where we would have this one. So, k_0^2 square of course is $\omega^2 \mu_0 \epsilon_0$. So, I am basically using this expression for $k y d$ square, when

alpha is equal to 0, $k_y d$ square will be equal to $\omega^2 \mu_0 \epsilon_0 n^2 d^2 - 1$ or $k_y d$ will be equal to $\omega \sqrt{\mu_0 \epsilon_0 n^2 d^2 - 1}$.

So, let us write down that. So, it would actually be ωc , which is the cut off frequency square root $\mu_0 \epsilon_0$ divided by 2, that is also a d here, then there is square root of $n^2 d^2 - 1$ okay. So, this must be equal to $n - 1$ into π , if you are going to this notation for the waves to be cutting off or rather this expression must be equal to $n - 1$ into π .

(Refer Time Slide: 26:19)

You can replace ωc by $2 \pi f c$ right and divide by 2, 2 will cancel, π will cancel from left hand and the right hand side. So, $f c$ can be written as $n - 1$, don't confuse n with refractive index, $n - 1$ is the mode designation divided by square root of $\mu_0 \epsilon_0 n^2 d^2 - 1$ under root. But I know $1/\sqrt{\mu_0 \epsilon_0}$ is c . So, I have $c n - 1$ divided by $d \sqrt{n^2 - 1}$.

So, these are the cut off frequencies for higher order mode. So with n is equal to 1, clearly $f c$ is equal to 0, indicating that no cut off for the fundamental mode okay. There will always be this particular mode, that would exist. So, there is no cut off for fundamental mode. So, for the odd modes, the cut off condition is this one, this is for the condition for odd TE modes okay. What would be the cut off condition for the even TE modes? You can actually show that, instead of \tan it would be \cot , so, I will not derive this one.

So, the cut off condition for the even frequency modes will be equal to $n - \frac{1}{2}$ divided by d into square root of $n^2 d^2 - 1$ okay. This minus half simply indicates a $\pi/2$ shift in the argument that needs to be used. But the important point is when n is equal to 1, f_c is not 0, which means that first the odd TE mode will propagate the fundamental, then the even TE mode will propagate.
