Time Domain Description of Hilbert Transform - Impulse Response of the Hilbert Transform

Welcome to another module in this massive open online course. So we are looking at the Hilbert transform for the generation of (oyo) single sideband modulated signals and we also looked at a frequency domain description of the Hilbert transform, alright.

(Refer Slide Time: 1:09)

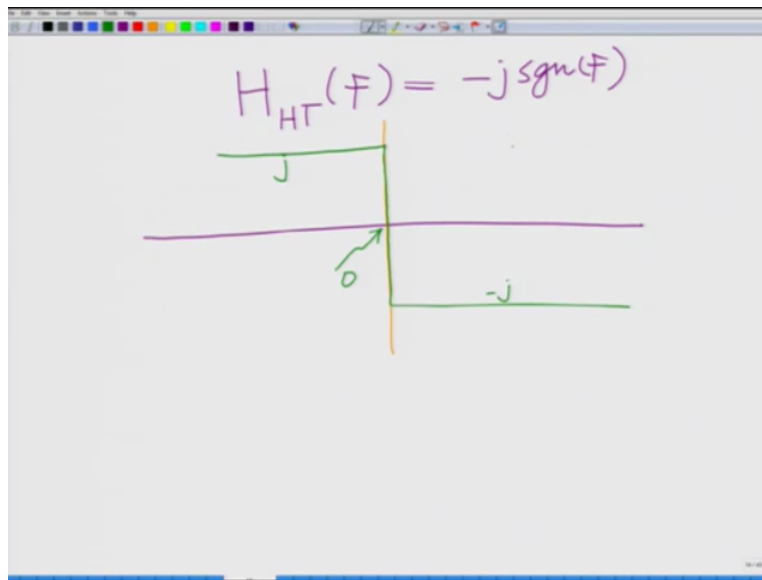

Impulse Response of Hilbert Transform — $h_{HT}(t)$

$$H_{HT}(F) = -j \operatorname{sgn}(F)$$

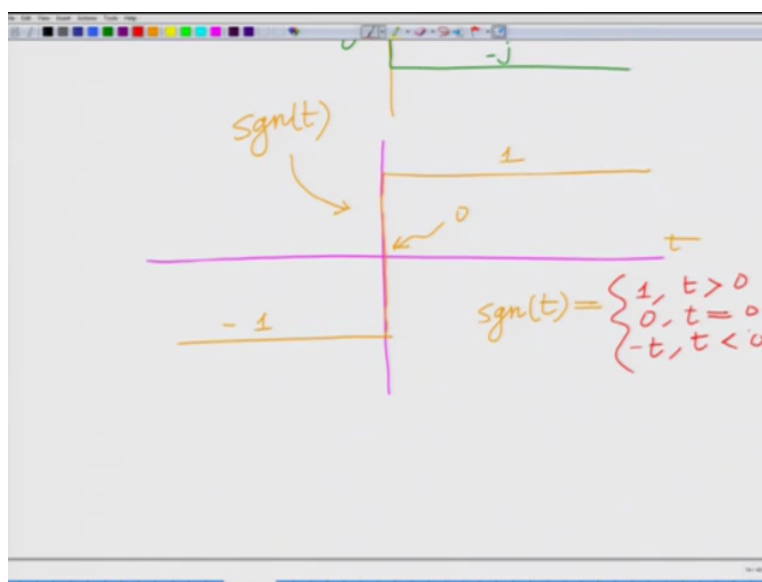

So now let us look at the time domain description that is the impulse response of the Hilbert transform. So we are looking at the impulse response of the (Hemb) Hilbert transform the impulse response of the Hilbert transform and we have denoted this by h_{HT} of t this is the impulse response of the Hilbert transform, alright.

(Refer Slide Time: 1:59)

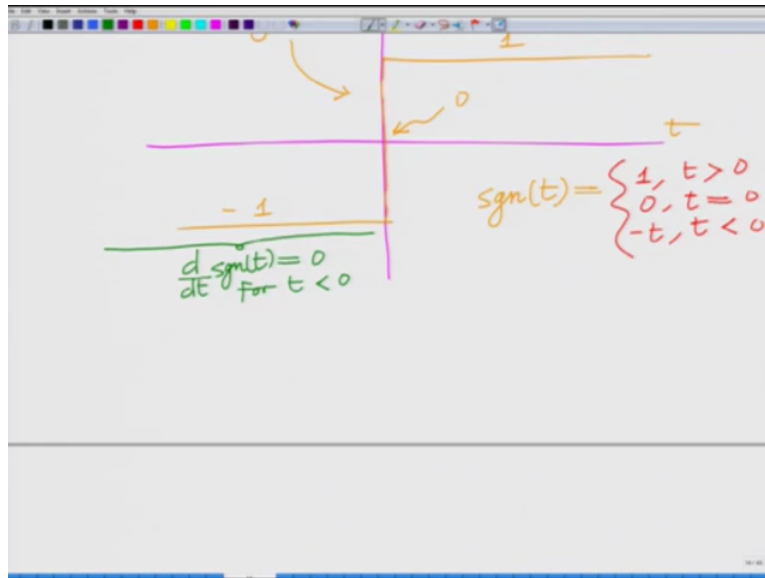

We are denoting it by hHT of t to start with let us recall that the frequency response of the Hilbert transform is minus $J \operatorname{sgn} F$ which looks something like this remember for convenience I can always denote it by this it's j for f less than 0 minus j for F greater than 0 and F equal to 0 this is 0. So this is your minus $j \operatorname{sgn} F$ to derive the impulse response of the Hilbert transform we already said that we are going to use that derivative property of the Fourier transform, alright. And I am going to talk about that shortly.

(Refer Slide Time: 3:04)

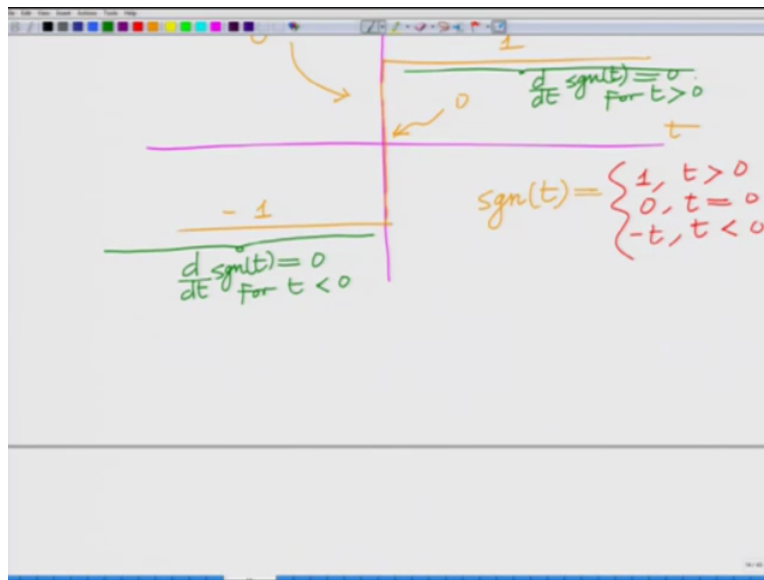

But first let us look at the derivative of the sgn function, let us go back looking at sgn of t, okay. So this is your sgn of t it is one for the greater than 0 minus one for t less than 0 and t equal to 0 it is 0. So sgn of t we already know sgn of t equals one for t greater than 0, 0 t equal to 0, minus t for t less than 0.

(Refer Slide Time: 3:26)

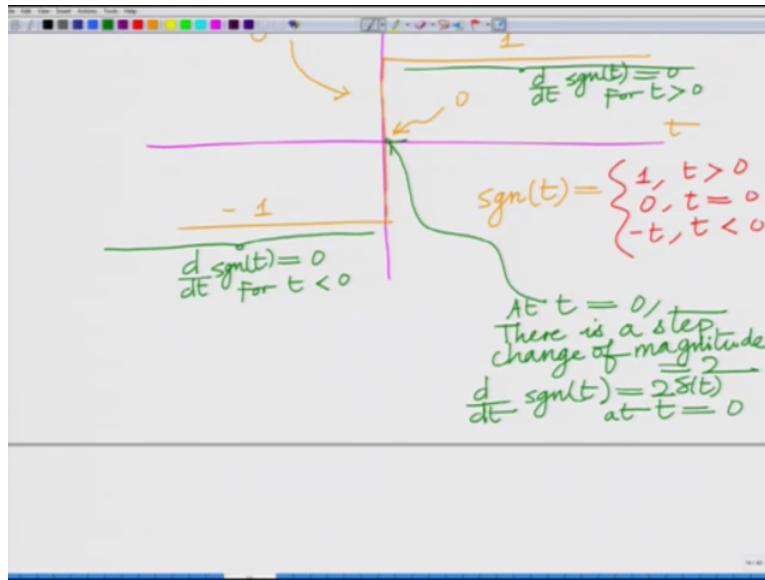

And now you can see the derivative of sgn of t, now here in this region sgn of t that is for t less than 0, sgn of t is constant. So in this region d by dt of sgn of t equal to 0 for t less than 0, right? You can see it is flat. For t less than 0 sgn of t is minus 1. So d by dt the derivative is 0 because it is a constant for t less than zero.

(Refer Slide Time: 3:54)

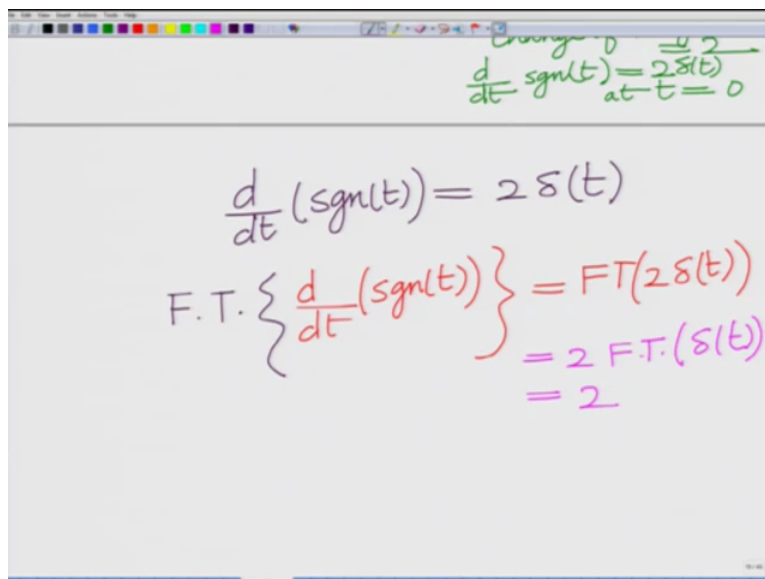

Similarly for t greater than 0 sgn of t is again a constant it is equal to one, so therefore the derivative is again 0, so in this region also d by dt sgn of t equal to 0 for t strictly greater than 0, alright. So for t both t strictly less than 0 and t strictly greater than 0 the derivative or sgn of t is 0 because sgn of t is constant in both these regions. The only place where the derivative of the sgn function that is sgn of t is nonzero is at the point t equal to 0 where it is transitioning from minus 1 to minus it takes a step jump from minus 1 to 1 and there the derivative you can see, since the magnitude is changing from minus 1 to 1 that is magnitude is changing by 2 the derivative is $2 \Delta t$, alright.

(Refer Slide Time: 4:45)

So in this position at t equal to 0 at t equal to 0 there is a step change of magnitude equal to 2 therefore d by dt of $\text{sgn } t$ equal $2\delta t$ at t equal to at t equal to 0. Therefore the derivative of this function, so you can see it is constant step change at t equal to 0 and again constant for t greater than or equal to 0, for t greater than 0 therefore the derivative is basically twice δt , alright. Since the change occurs only at so t equal to 0.

(Refer Slide Time: 5:39)

So therefore d by dt of sgn t equals two delta t which is nonzero only for t equal to zero, okay which implies, now let us start with the Fourier transform of the derivative I will show why this is convenient to find the Fourier transform the original function. Fourier transform of d by dt of Fourier transform of d by dt of sgn t d by dt of sgn t is 2delta t therefore the Fourier transform of d by dt sgn t equals the Fourier transform of 2delta t but the Fourier transform of 2delta t is simply 2 because of Fourier transform or we can write one more step that is twice the Fourier transform of delta t which is equal to two, right? Fourier transform of Delta t is simply one over the entire frequency domain.

(Refer Slide Time: 7:00)

$() = 2 \text{ F.T. } (\delta(t))$
 $= 2$

Derivative Property of FT

$x(t) \longleftrightarrow X(F)$

$\text{F.T.} \left(\frac{d}{dt} x(t) \right) \longleftrightarrow j2\pi F X(F)$

$\text{F.T.} \left(\frac{d}{dt} \text{sgn}(t) \right) = j2\pi F \text{ FT}(\text{sgn}(t))$

However we also have a result which states that the derivative of that is the Fourier transform of the derivative of a function that is if consider this is the derivative property of the Fourier transform states that if a signal $x(t)$ has Fourier transform $X(F)$ than the derivative of $x(t)$ that is if I look at the derivative of $x(t)$, the Fourier transform of the derivative of $x(t)$ is $j 2\pi F$ times $X(F)$. The Fourier transform of the derivative of a signal $x(t)$ is $j 2\pi F X(F)$ where $X(F)$ is a Fourier transform of $x(t)$.

And using this property the Fourier transform of the derivative of sgn t therefore the Fourier transform of the derivative that is the FT of the derivative of sgn t that is $j 2\pi F$ Fourier transform of sgn t however we have already seen that the derivative of the Fourier transform of sgn t from here. We have seen that the derivative of the Fourier transform of sgn t is 2 alright and therefore

this is also equal to from above this is also equal to this result we have from above implies that these 2 must be equal.

(Refer Slide Time: 9:25)

The image shows a whiteboard with handwritten mathematical derivations. At the top, there is a pink arrow pointing from the number '2' in the equation below to the text '2 (From above)'. The main derivation consists of two lines of equations:

$$\Rightarrow j2\pi F \text{ F.T.}(\text{sgn}(t)) = 2$$

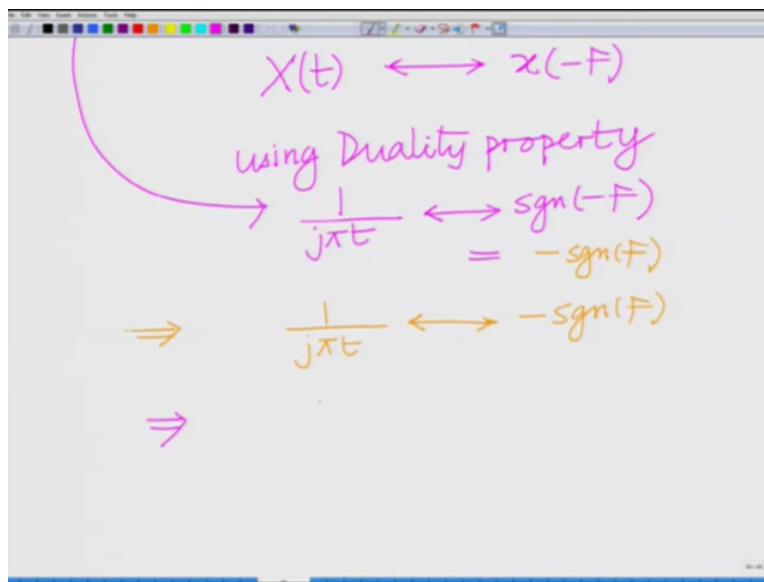

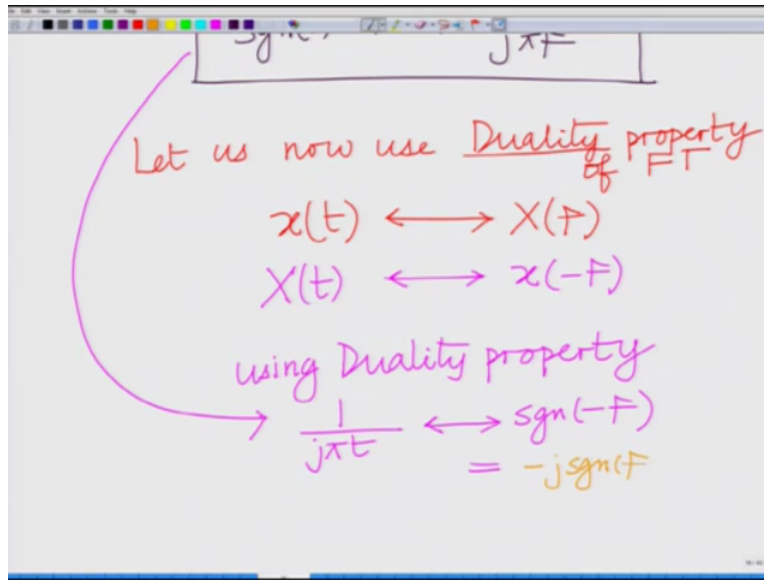

$$\Rightarrow \text{F.T.}(\text{sgn}(t)) = \frac{2}{j2\pi F} = \frac{1}{j\pi F}$$

Below these equations, a horizontal line separates them from a boxed result:

$$\boxed{\text{sgn}(t) \longleftrightarrow \frac{1}{j\pi F}}$$

So this implies we must have $j2\pi F$ Fourier transform of $\text{sgn } t$ equals 2, alright. We have already shown that the derivative of the Fourier (trans) that that the derivative that is the derivative of $\text{sgn } t$ is $2\delta t$ therefore the Fourier transform of the derivative of $\text{sgn } t$ is 2 and we also it is all from the derivative property of the Fourier transform we are saying that the derivative of $\text{sgn } t$ has a Fourier transform that is $j2\pi F$ times the (fou) the Fourier transform of $\text{sgn } t$ therefore the issue quantities must equal be equal which implies $j2\pi F$ Fourier transform of $\text{sgn } t$ equals 2 which implies that Fourier transform of $\text{sgn } t$ equals 2 by $j2\pi F$ which is basically equal to 1 by $j\pi F$, therefore $\text{sgn } t$ Fourier transform $\text{sgn } t$ has the Fourier transform 1 by j 1 over $j\pi F$ this is the property that we have been able to ((10:39) $\text{sgn } t$ has the (pou) Fourier transform 1 over $j\pi F$, alright.

(Refer Slide Time: 10:52)

And now let us use (pru) duality let us now use duality and using duality remember duality states that if $x(t)$ has duality property of Fourier transform which states that if $x(t)$ has Fourier transform $X(F)$ then $x(t)$ has Fourier transform x of minus F using the duality property we have $\text{sgn } t$ has Fourier transform 1 by $j\pi$. So using the duality property of $\text{sgn } t$ has Fourier transform 1 by $j\pi$ 1 by $j\pi$ has Fourier transform x of minus F that is sgn of minus F .

Now remember sgn function is an odd function, right? Because it is 1 for t (greater) $\text{sgn } t$ is 1 for t greater than 0 minus 1 for t less than 0 . 0 at equal to 0 this is an odd function. So sgn of minus F

is minus $j \operatorname{sgn} F$. This is sgn in the frequency domain by the way, so this is minus which is exactly what we want for the Hilbert transform this is minus $j \operatorname{sgn} F$ this implies that 1 by $j \pi t$ has Fourier transform minus sgn . I am sorry not minus sgn of minus F is minus minus $\operatorname{sgn} F$, so 1 by $j \pi t$ has Fourier transform minus $\operatorname{sgn} F$ which implies.

(Refer Slide Time: 13:05)

The image shows a whiteboard with handwritten mathematical notes. At the top, there is a small header with a color bar and some icons. The main content consists of two lines of equations:

- The first line shows an orange arrow pointing to the right, followed by the equation $\frac{1}{j\pi t} \longleftrightarrow -\operatorname{sgn}(F)$.
- The second line shows a purple arrow pointing to the right, followed by a purple box containing the equation $\frac{1}{\pi t} \longleftrightarrow \frac{-j \operatorname{sgn}(F)}{1}$.

Below the purple box, there are two labels with arrows pointing to the terms in the equation:

- A green label $h_{HT}(t)$ with an arrow pointing to $\frac{1}{\pi t}$.
- A purple label $H_{HT}(F)$ with an arrow pointing to $-j \operatorname{sgn}(F)$.

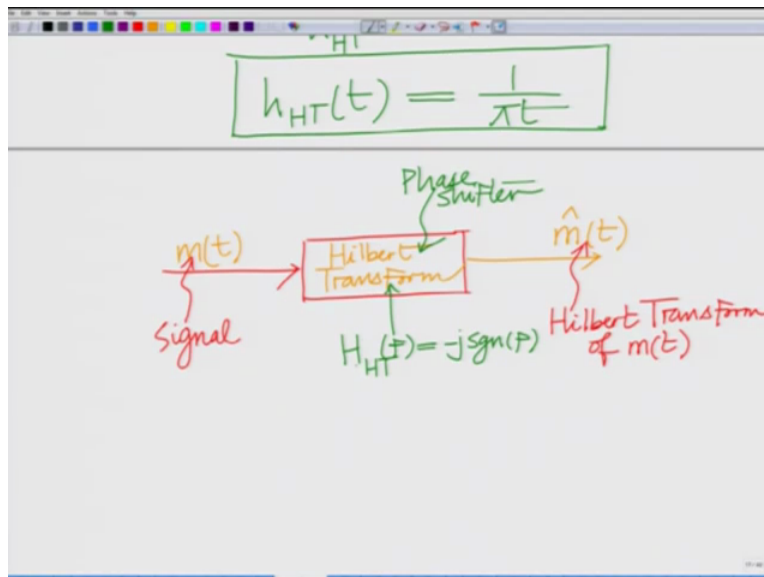

Now taking the j to the other side 1 by πt has the Fourier transform minus $j \operatorname{sgn} F$, 1 by πt has the Fourier transform of minus $j \operatorname{sgn} F$, now minus $j \operatorname{sgn} F$ is nothing but recall that minus $j \operatorname{sgn} F$ is nothing but the impulse response of the Hilbert transform H_{HT} of F which implies that 1 by πt which is the inverse Fourier transform of this must be nothing but the impulse response of the Hilbert transform therefore the impulse response of the Hilbert transformer is 1 by πt .

(Refer Slide Time: 14:08)

A screenshot of a whiteboard showing the impulse response of the Hilbert Transform. The equation $h_{HT}(t) = \frac{1}{\pi t}$ is written in green ink and enclosed in a green rectangular box. Above the box, a purple bracket spans the width of the box, with an arrow pointing to the label $h_{HT}(t)$ on the left and another arrow pointing to the label $H_{HT}(F)$ on the right.

And that is what we have derived H of HT of t equals 1 by π 1 by equals 1 by π t , okay. So that is a property that we have been able to show that the impulse response of the, that is if remember the Hilbert transform is a linear time invariant system whose Fourier transform is given by minus $j \text{sgn } F$. In the time domain its impulse response is 1 by π t therefore now if you look at the Hilbert transform remember the Hilbert transform is an LTI system, correct?

(Refer Slide Time: 14:44)

This is your Hilbert transform is an LTI system if you pass a signal $m(t)$ out comes the Hilbert transform $\hat{m}(t)$ of t this is your signal this is its Hilbert transform of $m(t)$ of $m(t)$ and now this system has (impu) Fourier transform we have already seen this equals minus $j \operatorname{sgn} F$ in fact this is a phase shifter, correct? Remember this is a phase shifter that is it shifts the phase of all the positive frequency components by minus π by two all the negative frequency components by π by two. This is a phase shifter it has (impu) frequency spectrum the Fourier transform is minus $j \operatorname{sgn} F$ and the frequency.

(Refer Slide Time: 16:10)

Handwritten notes on a whiteboard showing the Hilbert transform. The notes include the frequency response $H_{HT}(F) = -j \operatorname{sgn}(F)$, the impulse response $h_{HT}(t) = \frac{1}{\pi t}$, and the time-domain equation $\hat{m}(t) = m(t) * \frac{1}{\pi t}$. The word "Signal" is written in red on the left, and "Hilbert Transform of $m(t)$ " is written in red on the right. A green box encloses the final equation.

And now the impulse response we have derived the impulse response h_{HT} of t equals one by πt which implies in the time domain the Hilbert transform can be represented equivalently as $\hat{m}(t)$ of t equals the input signal remember when you pass input signal through LTI system signal gets convolved with the impulse response, so $m(t)$ convolved with $1/\pi t$.

(Refer Slide Time: 17:18)

The image shows a whiteboard with a handwritten equation: $\hat{m}(t) = m(t) * \frac{1}{\pi t}$. The equation is enclosed in a green rectangular box. Above the box, the words "HT" and " πt " are written. Below the box, there are two handwritten annotations: "Time Domain Representation of Hilbert Transform" in orange, with an arrow pointing to the $\hat{m}(t)$ term, and "Convolution in Time Domain" in purple, with an arrow pointing to the convolution symbol $*$.

This is the time domain representation of the Hilbert transform this is the time domain representation of the Hilbert transform and this is remember convolution this is a time domain representation therefore it is a convolution in time domain. That is convolution of the input signal with the impulse response.

(Refer Slide Time: 17:22)

The image shows a whiteboard with handwritten equations. At the top, "Convolution in Time Domain" is written in purple. Below it, the following equations are written in orange: $\hat{M}(F) = M(F) \cdot H_{HT}(F)$, $= M(F) \cdot -j \operatorname{sgn}(F)$, and $\hat{M}(F) = -j \operatorname{sgn}(F) M(F)$. The last equation is enclosed in a yellow rectangular box. Below the box, there are two handwritten annotations: "Frequency Domain Representation of HT." in red, with an arrow pointing to the $\hat{M}(F)$ term, and "Multiplication in Frequency Domain." in purple, with an arrow pointing to the $M(F)$ term.

Now frequency domain representation that is the output Fourier transform remember convolution in time domain is multiplication in the frequency domain, so this is MF into H HT of F which is

basically your $M F$ times minus j a product, correct? This is a product or you can write this as minus j times F , okay. So this is the product in the frequency domain. So this is the frequency domain representation of HT Hilbert transform and this is a multiplication in the frequency domain alright.

So in this module we have developed the time domain representation of the impulse of the Hilbert transform that is we have calculated the impulse response of the Hilbert transformer using 2 properties one is the derivative property of the Fourier transform and the duality property of the Fourier transform to demonstrate that the impulse response of the Hilbert transform is 1 over πt which corresponds to the spectrum of the Fourier transform of the Hilbert (transform) transform which is given by or the spectrum of the Hilbert transformer which is given by minus j times F , alright.

And therefore Hilbert transform can be represented in the time domain also equivalently by the convolution $\hat{m}(t)$ which is a Hilbert transform of $m(t)$ is given by the convolution of $m(t)$ with 1 over πt . However as you can see since 1 over πt is a messy signal, correct? 1 over πt is a quite a messy signal therefore it is much more easily and readily expressed in the it is much more this signal is much more readily expressed in the in the the Hilbert transform the operation of the Hilbert transform is much more readily expressed in the frequency domain rather than the time domain.

So the frequency domain specification of the Hilbert transform which is in the phase shifting property that is minus j times F , alright where it's which shifts the phase of all the positive frequency components by minus π by 2 and the negative frequency components by π by 2 is much more simpler compared to the times domain description of the Hilbert transform, alright. So we will stop this point over here and continue with the other aspects in the subsequent modules, thank you.
