**Modulation Property of Fourier Transform, Dirac Delta or Unit Impulse Function-
Definition and Fourier Transform**

Hello, welcome to another module in this massive open online course, alright. So let us continue our discussion on the Fourier transform, correct. Let us now look at the properties of the Fourier transform, let us look at the modulation property of the Fourier transform, alright. So let us look at the modulation that is what happens to the Fourier transform of a signal which is modulated, alright. So this is the modulation property of Fourier, transform.

(Refer Slide Time: 1:07)

MODULATION PROPERTY
OF FOURIER TRANSFORM

$$\tilde{x}(t) = x(t) \cdot e^{j2\pi f_c t}$$

Modulation

Signal carrier complex Sinusoid

Modulated Signal $f_c = \text{carrier Frequency}$

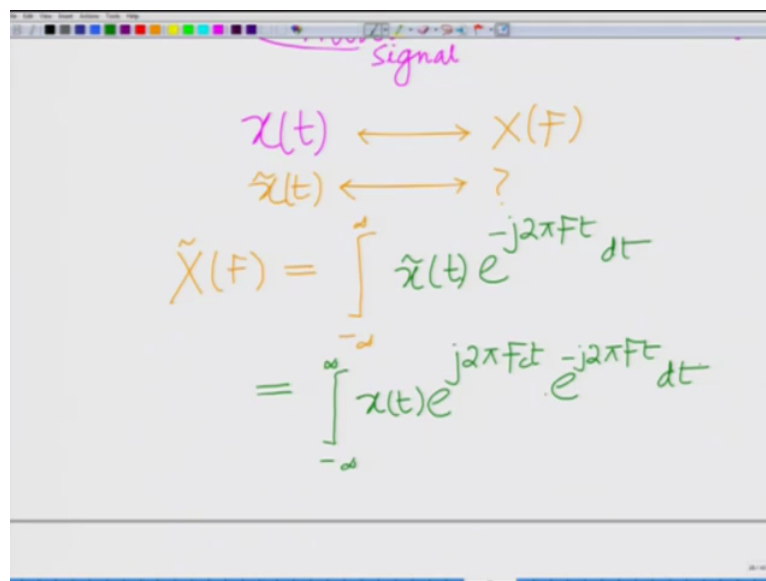

What we mean by modulation? Modulation simply refers to the operation that is $\tilde{x}(t)$, which is $x(t)$ multiplied by a complex a Sinusoid with a very high frequency that is multiplied by a Sinusoid at a very high frequency, in fact, this is 1 of the most fundamental principles of communication, that is this is a complex Sinusoid. This is which is termed as the carrier and this f_c that is this quantity f_c this is the carrier, this quantity f_c is the carrier frequency, alright. So we multiply with the Sinusoid this quantity f_c this denotes the carrier frequency and $x(t)$ is your signal and $\tilde{x}(t)$ is termed as the modulated signal, this is termed as the modulated signal, this is this process is modulation.

Now in general when we modulated because here we are employing a complex Sinusoid in general we employ a real signal that is either a cosine or a sine signal, alright but in general

so but this (prop) but in principle this can be presented as $x(t)$ multiplied by this complex Sinusoid $e^{j 2 \pi F_c t}$ is a complex Sinusoid at the carrier frequency F_c , alright. $e^{j 2 \pi F_c t}$ is the complex carrier F_c is the carrier frequency and this carrier frequency is much higher that is in communication system, this carrier frequency is much higher typically much higher than the maximum frequency orders of magnitude higher than the maximum frequency of the or maximum much higher than the bandwidth of the signal $x(t)$, alright and this process is termed as modulation.

Of course, we are going to keep encountering this frequently, right? As we go through the various modules in this course principles of modulation in various communication system. We are going to keep encountering this very frequently and this is a very key aspect a very important step in any communications system, alright. Now what happens to the Fourier transform under modulation? That is if I consider a signal $x(t)$ which has Fourier transform that is Fourier transform pair with that is $x(t)$ which has Fourier transform FF $X(F)$.

(Refer Slide Time: 4:31)

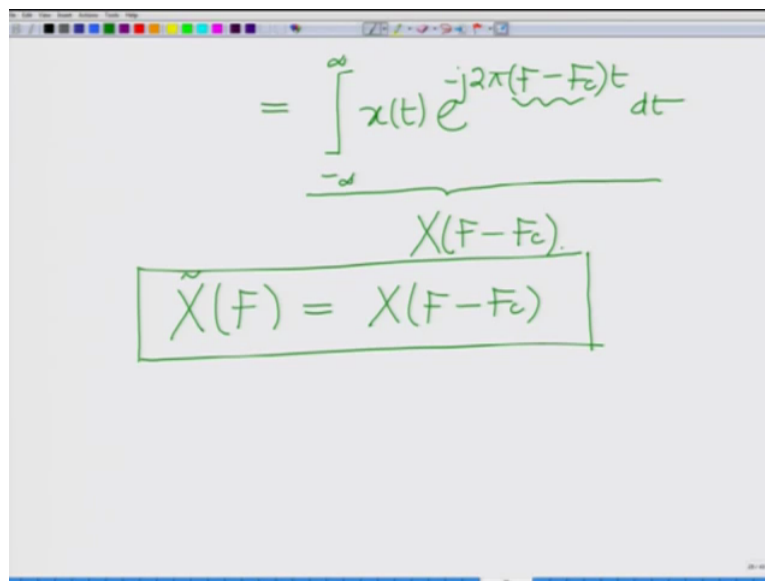

The image shows a digital whiteboard with handwritten mathematical derivations. At the top, the word "Signal" is written in purple. Below it, two Fourier transform pairs are shown with orange double-headed arrows: $x(t) \longleftrightarrow X(F)$ and $\tilde{x}(t) \longleftrightarrow ?$. The main derivation for $\tilde{X}(F)$ is written in orange and green:

$$\tilde{X}(F) = \int_{-\infty}^{\infty} \tilde{x}(t) e^{-j2\pi Ft} dt$$

$$= \int_{-\infty}^{\infty} x(t) e^{j2\pi Ft} e^{-j2\pi Ft} dt$$

Now what is the Fourier transform of the modulated signal $\tilde{x}(t)$, well $\tilde{x}(F)$ equals to minus infinity to infinity, I can write this as $x(t)$ or $\tilde{x}(t) e^{j 2 \pi F_c t}$ to the power of $-j 2 \pi F t$ dt, which is substituting the expressions for $\tilde{x}(t)$ that is $x(t) e^{j 2 \pi F_c t}$ to the power of $-j 2 \pi F t$ dt which is equal.

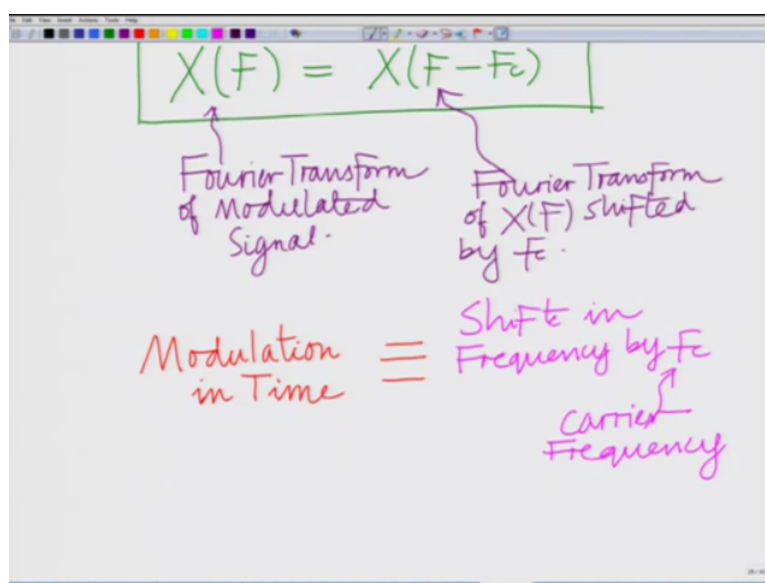

(Refer Slide Time: 5:57)

The image shows a handwritten derivation on a digital whiteboard. At the top, the integral
$$= \int_{-\infty}^{\infty} x(t) e^{-j2\pi(F-F_c)t} dt$$
 is written. A bracket underneath the integral points to the expression $X(F-F_c)$. Below this, the final result is boxed:
$$\tilde{X}(F) = X(F-F_c)$$

Now you can write this as $x(t) e^{-j2\pi(F-F_c)t}$ and now you can see this is nothing but the Fourier transform of X evaluated at the frequency $F - F_c$. So what we have, we have this interesting result we have $\tilde{X}(F)$ the Fourier transform of the modulated signal is simply $X(F - F_c)$, it is a very interesting result and as I said since modulation is a very important step or a very important aspect of any communication system, this principle is used very frequently is very important in communication that is what we have seen is $\tilde{X}(F)$ is $X(F - F_c)$ that is $\tilde{X}(F)$ the Fourier transform of the modulated signal is $X(F - F_c)$ that is, it is simply a shifted version.

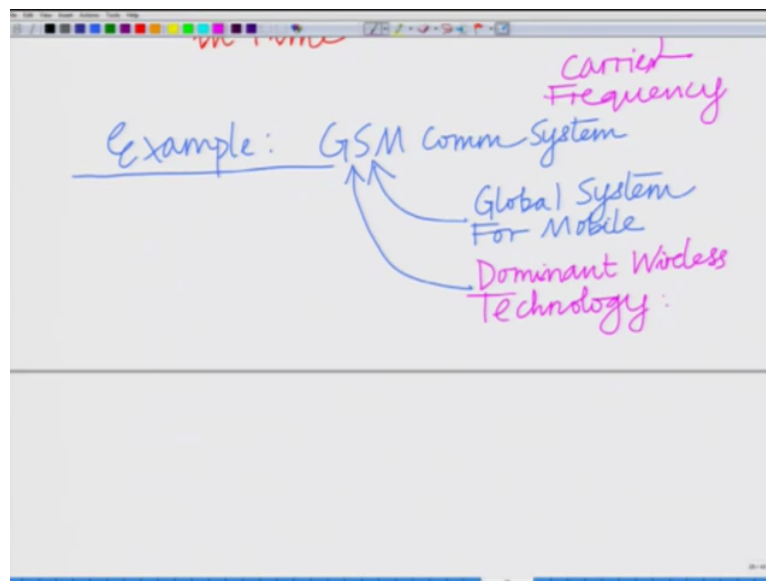

(Refer Slide Time: 7:28)

The image shows a handwritten explanation on a digital whiteboard. At the top, the equation
$$\tilde{X}(F) = X(F-F_c)$$
 is boxed. Two arrows point from the text below to the terms in the equation. The left arrow points to $\tilde{X}(F)$ and is labeled "Fourier Transform of Modulated Signal". The right arrow points to $X(F-F_c)$ and is labeled "Fourier Transform of $X(F)$ shifted by F_c ". Below these, the text "Modulation in Time" is written in red, followed by an equals sign, and then "Shift in Frequency by F_c " is written in purple. An arrow points from "Shift in Frequency by F_c " to the word "Carrier Frequency" written below it.

That is $X(F) - F_c$ is the Fourier transform of $X(F)$ shifted to F_c that is shifted by F_c , correct. So what we have is $\tilde{x}(F)$ this is the Fourier transform this is simply the Fourier transform of $X(F)$ shifted by F_c . That is, so modulation in time so the principle is modulation in time. If you modulate modulation in time, this is equivalent to shift in frequency by F_c , where F_c we know is the carrier frequency. So modulation in time so if you modulate the signal in time that is simply that can be vision as take the original spectrum and shift it the frequency domain by F_c , where F_c is the carrier frequency.

(Refer Slide Time: 9:16)

And this is an important principle in the communication systems as I have already said for instance let us take a simple example to understand this in a practical communication system, correct. Let us consider a GSM communication system as you all must be familiar, GSM is a wireless standard it stands for Global System For Mobile Communication and in fact it is one of the most popular wireless system wireless technology, wireless standards one of the most popular wireless technology which is used by a large number of wireless cellular user, alright, so GSM is the global for mobile and it is a very dominant wireless

(Refer Slide Time: 10:33)

For instance, let us take a simple GSM, let us GSM if you look at the original signal, correct. What is termed it as a bandwidth of W equals to 100 kilohertz centered at frequency 0, so this is the original message spectrum or the original message; this is the original message signal spectrum for the purpose of transmission this is modulated to a very high carrier frequency.

(Refer Slide Time: 11:24)

So this is modulated by a very high carrier frequency, I am not drawing it according to scale, alright. So it is modulated to a very high carrier frequency which is simply, so now it is shifted by F_c , so this will be $F_c - w$ $F_c + w$, so this is shifted to F_c we have already seen F_c as the carrier frequency and in GSM typically F_c equals to either 900 megahertz or 1800 megahertz.

(Refer Slide Time: 12:33)

So what you are seeing here is that you are having an original GSM signal the message signal, which is of a bandwidth 100 kilohertz centered at frequency 0, correct? Now for the purpose of transmission I have to employ a very high carrier frequency in GSM employs a very high carrier frequency, which is 900 megahertz are typically around 1800 Megahertz and therefore this message spectrum is modulated with the carrier at 900 megahertz, which means original spectrum which is centered at 0 is shifted to the carrier frequency that is at 900 megahertz or 1800 megahertz depending on the carrier frequency.

Now the other thing that you can observe is the signal bandwidth is 100 kilohertz, right, which is of the order of 10 to the power of 3 , correct or 10 to the power of 5 , 100 kilohertz that is 100 into 10 to the power of 3 , so 10 to the power of 5 , but the carrier frequency is 900 megahertz which is 900 into 10 to the power you can roughly say 1000 megahertz, 1000 megahertz that is 1 gigahertz that is 10 to the power of 9 . So your original message is of bandwidth 10 to the power around 10 to the power of 5 and when you translate it the transmitted symbol that is a modulated signal or the carrier has a frequency that is order of 10 to the power of 9 .

So you can see that the carrier frequency F_c is much larger than the message bandwidth and this has a reason we are going to explain it in greater detail once we come to the modulation aspect, but you can see the modulating frequency the carrier frequency is much higher than the message bandwidth and this is a very important principle in communication. So we can see basically that F_c , so what you can see is that your F_c equals to 900 Megahertz is much

larger than w which is equals to hundred kilohertz and this w is equals to the message bandwidth.

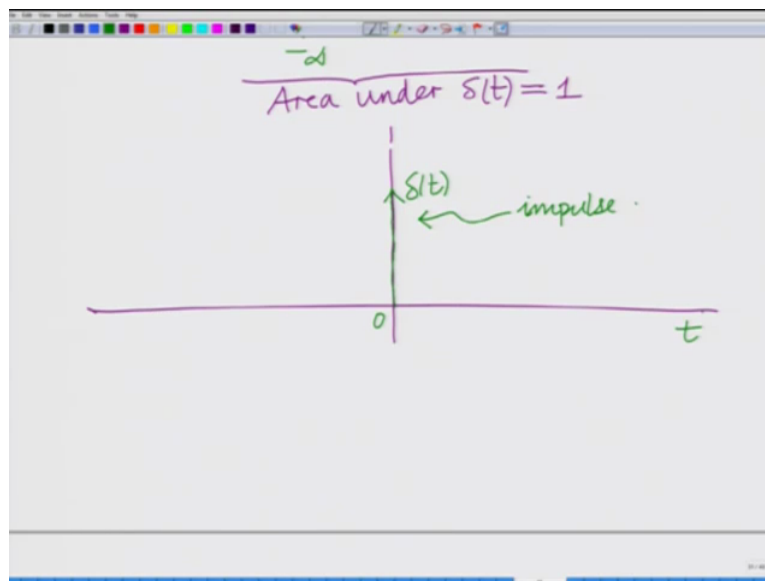

And this is also termed as the, this original message signal is also termed as the baseband signal this baseband signal, alright be centered at 0 frequency modulated to a very high carrier frequency and transmitted over the wireless radio channel and this is the principal of modulation, modulation means basically transmitting physically multiplying by a Sinusoid of a very high carrier frequency for the purpose of transmission, okay alright, so this is an important principle of communication. Now let us look at a very special function in both signal processing and communication for which we want to compute the Fourier transform and this is basically the unit impulse function.

(Refer Slide Time: 15:55)

UNIT IMPULSE FUNCTION:
DIRAC DELTA FUNCTION $\delta(t)$
 $\delta(t) = 0$ For $t \neq 0$
For $t = 0$, Not Defined
 $\int_{-\infty}^{\infty} \delta(t) = 1$

So let us start looking at another very interesting and important function, which is the unit impulse function. Now, this unit impulse function this is also known as the Dirac Delta function denoted by $\delta(t)$, this is the Greek symbol for Delta and this is represented in the time domain. Well, let us first define this Delta T, this direct Delta function is defined as 0 for all $t \neq 0$, and for $t = 0$ it is not really defined that delta function for $t = 0$ it is not really defined not particularly defined. However, the integral - infinity to infinity of $\delta(t)$ this is equals to unity that is the area under this function that is if I look at this function the area under this, okay. The area under this Direct Delta function is always unity.

(Refer Slide Time: 17:46)

That is it is 0 everywhere, so value at 0 is not defined however, the area under this that is integral from - infinity to infinity delta (t) that is basically unity that is basically always a constant, that is 1. And it is represented as follows the special function this Delta function is represented as follows that is I have 0 everywhere and at 0 it is represented using an impulse. Our unit this arrow this line with arrow pointing upwards is known as an impulse. That is it a 0 everywhere and at 0 its value is not defined, so it is shown with an arrow which is pointing upwards is also termed as an impulse for as we said the unit impulse function typically also termed simply as an impulse its meaning is evident from the (con) context. And the way to understand this impulse is, it cannot be described it cannot be visualize intuitively.

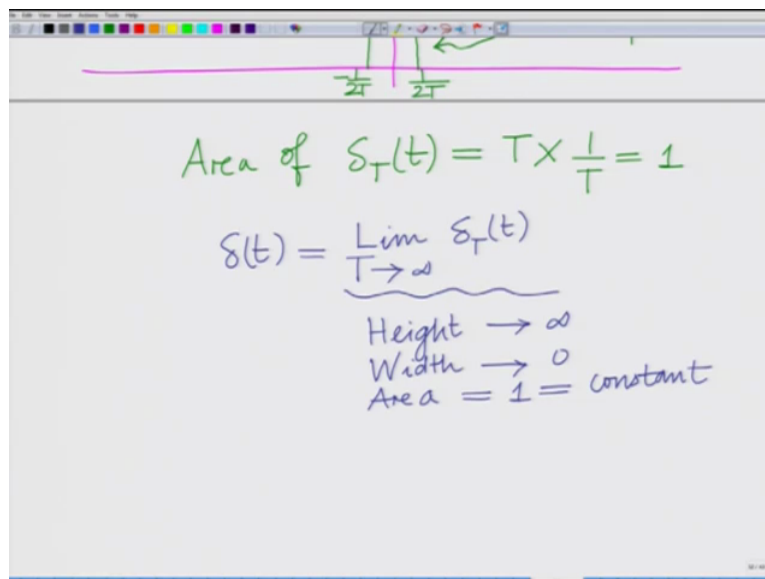

(Refer Slide Time: 19:15)

The way to understand this is basically, think of a pulse that is the way to understand this special function which is the impulse is to think about a pulse which is of height T of width $\frac{1}{T}$ over T . So this so it expands $\frac{1}{2T} - \frac{1}{2T}$ to $\frac{1}{2T}$, so width equals to $\frac{1}{T}$, alright. So area of the pulse, let us denote this pulse by $\delta_T(t)$ of sub capital T of t , Area, now you can see the area for any capital T , the area of $\delta_T(t)$ is basically its height, which is equals to the area is basically the height which is equals to T into the width which is $\frac{1}{T}$ which is equals to unity.

So we can think of a height, we impulse with height T , width $\frac{1}{T}$ spanning from $-\frac{1}{2T}$ to $\frac{1}{2T}$, so that the area is basically always capital T into $\frac{1}{T}$, which is basically 1 this is unity, alright. Now as the limit T tends to 0, now as a limit T tends to infinity, which means the height keeps increasing and the width keeps shrinking yet the area under it is a constant in the limit capital T tends to infinity and becomes the unit impulse function.

(Refer Slide Time: 21:33)

Area of $\delta_T(t) = T \times \frac{1}{T} = 1$

$\delta(t) = \lim_{T \rightarrow \infty} \delta_T(t)$

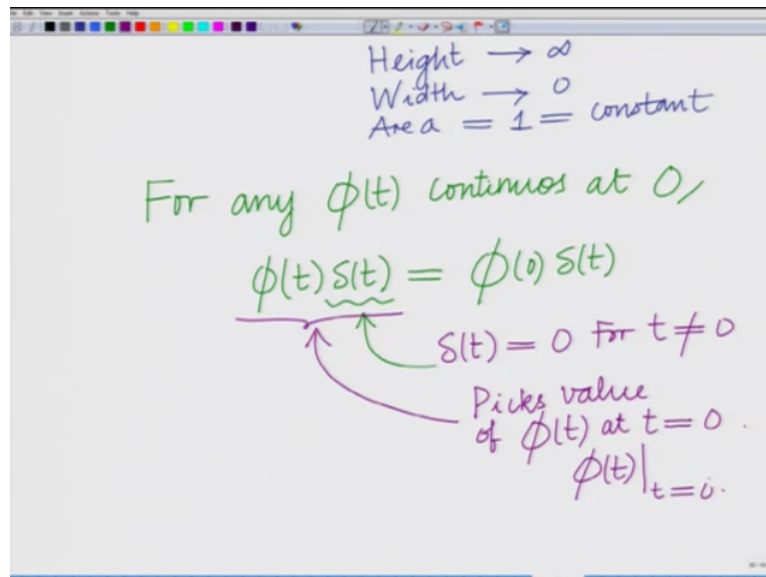

Height $\rightarrow \infty$
 Width $\rightarrow 0$
 Area = 1 = constant

So delta T can be understood as the limit, one way to understand delta T is the limit as T tends to infinity of delta T which means that is this means height of the pulse tends to infinity, width tends to 0, and however area is 1 which is a constant. So this is basically 1 way to sort of intuit sort of visualize this unit impulse function which otherwise is very difficult to visualize or understand intuitively, alright.

Think of it as a pulse width $\frac{1}{T}$ height capital T as the limit T tends to infinity, so that the width shrinks to 0, the height really becomes the height really becomes infinity, alright. And this impulse has several interesting properties, alright, so let us look at and it is

important to understand these properties and this is important to use and we are going to use this function very frequently to study or to define the various aspects and study the various properties of the medication systems, alright.

(Refer Slide Time: 23:02)

So the impulse has several interesting properties, alright. For instance, for any function and a continuous function Φ of t , for any continuous function Φ of t for any function Φ of t continuous at 0, alright. Need not be continuous in general for any function Φ of t continuous at 0 $\Phi(t)\delta(t)$ equals to $\Phi(0)\delta(t)$. And this is natural since $\delta(t)$ equals to 0 for any $t \neq 0$, so $\delta(t)$ is 0 for any $t \neq 0$, so $\Phi(t)\delta(t)$ equals to 0 even $\Phi(t)$ is continuous at 0. It is simply $\Phi(0)\delta(t)$. So $\delta(t)$ is sort of picking the value of this function Φ of t at t equals to 0. So sort of picks or if you can put it over here picks of this operation, this operation picks so this picks value of Φ of t at equals to 0. Picks value of Φ of t at t equals to 0 that is $\Phi(t)$ at evaluated at t equals to 0.

(Refer Slide Time: 25:42)

Further,

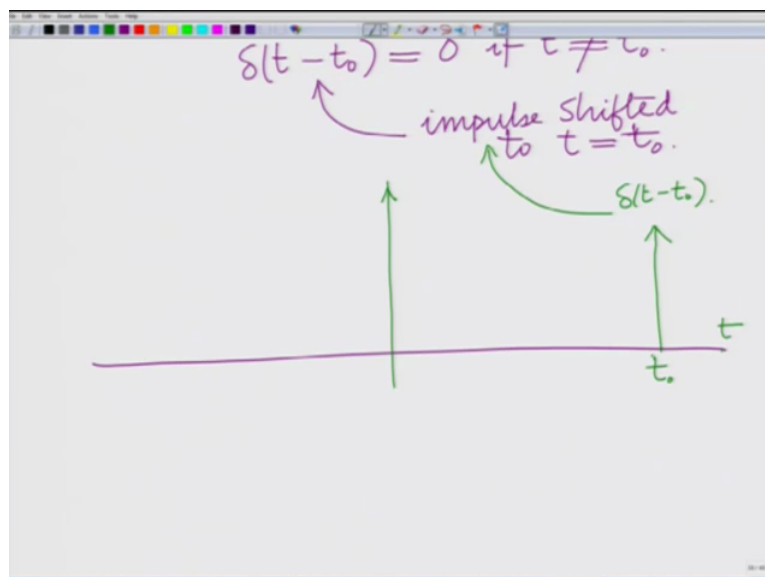

$$\int_{-\infty}^{\infty} \phi(t) \delta(t) dt = \int_{-\infty}^{\infty} \phi(0) \delta(t) dt$$

$$= \phi(0) \int_{-\infty}^{\infty} \delta(t) dt = \phi(0).$$

$$\boxed{\int_{-\infty}^{\infty} \phi(t) \delta(t) dt = \phi(0).}$$

Now naturally further integral - t to - infinity to infinity Φ of t delta t by the ϕ property is integral Φ of 0 delta t dt, Φ of 0 is constant, so it comes out of the integral so this is nothing by Φ of 0 integral - infinity to infinity delta t dt this is equals to Φ of 0, alright. So what we have is basically integral - infinity to infinity, Φ of t dt equals to Φ of 0, okay. So that is for any function Φ which is continuous at t equals to continuous at t equals to. Now let us consider a shifted version of this impulse that is shifted to t_0 that is delta $t - t_0$.

(Refer Slide Time: 27:12)

So let us consider delta $t - t_0$ naturally this is 0 for every t_0 equals to t not, correct, what is this? This is impulse shifted to t equals to t_0 therefore you have your axis, correct, your time axis, this is your time and this denotes the impulse shifted to t_0 , alright. So this is

basically your $\delta t - t_0$, alright this is the time axis, so this is your impulse shifted to t equals to t_0 .

(Refer Slide Time: 28:29)

$$\phi(t) \delta(t - t_0) = \phi(t_0) \delta(t - t_0)$$

For any function $\phi(t)$ continuous at $t = t_0$.

Naturally, ϕ of t again ϕ of t into $\delta t - t_0$, since $\delta t - t_0$ is 0, for all t_0 equals to t_0 , this is simply ϕ of t_0 into $\delta t - t_0$, correct, so this is obviously for any function ϕ of t , continuous at t equals to t_0 . Now I have to qualify the statement, this is for any function of ϕ of t continuous at t equals to t_0 .

(Refer Slide Time: 29:25)

Picks value of $\phi(t)$ at $t = t_0$.

$$\int_{-\infty}^{\infty} \phi(t) \delta(t - t_0) dt = \int_{-\infty}^{\infty} \phi(t_0) \delta(t - t_0) dt = \phi(t_0)$$

For any function $\phi(t)$ continuous at $t = t_0$.

Further, if I integrate this that is integral - infinity to infinity ϕ of t $\delta t - t_0$ dt this is naturally integral of ϕ of t_0 $\delta t - t_0$ dt , which is ϕ of t_0 , okay. So this is basically picks

the value or picks the value of Φ of t that is $\int_{-\infty}^{\infty} \Phi(t) \delta(t - t_0) dt$ from $-\infty$ to ∞ is basically $\Phi(t_0)$, alright. Basically, it picks the value of Φ of t the function Φ of t at t equals to t_0 , provided Φ of t is continuous at t equals to t_0 , alright. So this is an important constraint on the qualification of this argument or this result to keep in mind, okay alright.

(Refer Slide Time: 30:44)

$$= \phi(t_0).$$

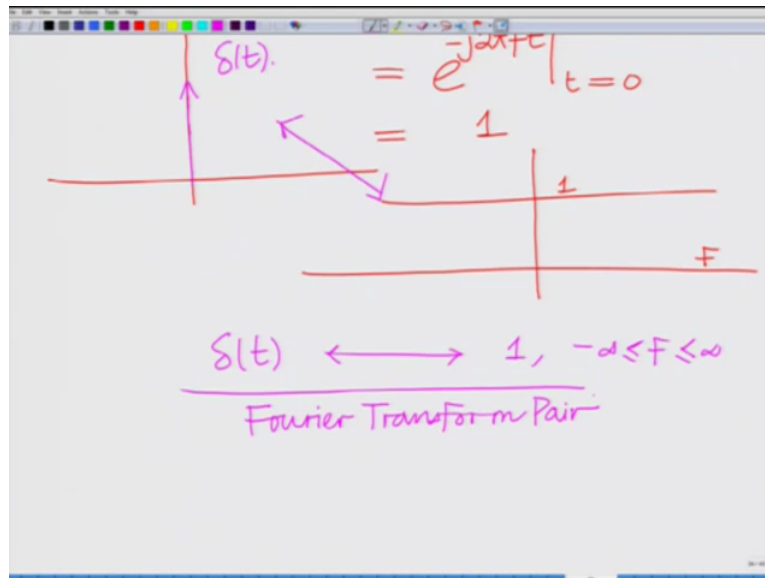

FOURIER TRANSFORM OF
UNIT IMPULSE

$$\text{F.T.}(\delta(t)) = \int_{-\infty}^{\infty} \underbrace{\delta(t)}_{\phi(t)} e^{-j2\pi ft} dt$$

$$= e^{-j2\pi ft} \Big|_{t=0}$$

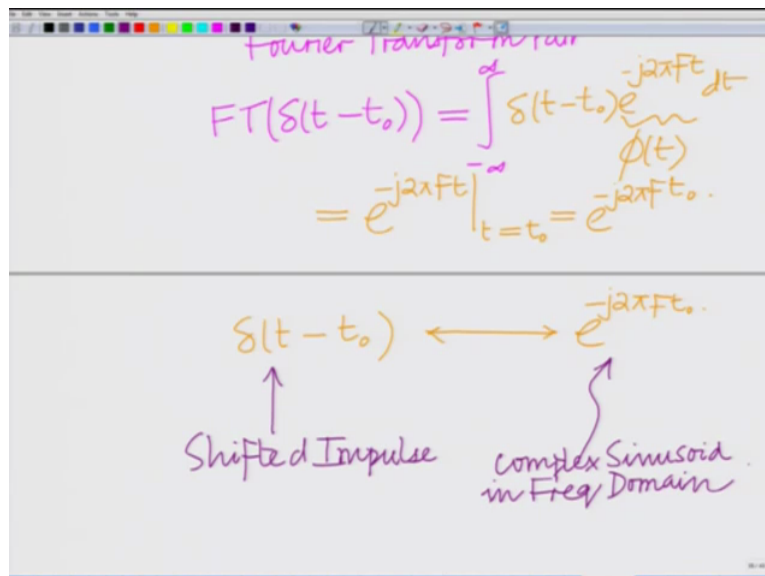

Now let us look at the Fourier transform of this unit impulse which is going to be very important, the Fourier transform of the unit impulse that is easy to evaluate that is your Fourier transform of $\delta(t)$, this is equals to $\int_{-\infty}^{\infty} \delta(t) e^{-j2\pi ft} dt$ alright, this is a standard expression for the Fourier transform and now you can treat this function Φ of t and by the property that we have shown before that is $\int_{-\infty}^{\infty} \delta(t) \Phi(t) dt$ is nothing but $\Phi(t)$ evaluated at t equals to 0. So this becomes $e^{-j2\pi ft}$ evaluated at t equals to 0 and $e^{-j2\pi ft}$ evaluated at t equals to 0 is 1, so this is simply basically just 1 at all frequencies the frequency domain, alright.

(Refer Slide Time: 32:25)

And this is the Fourier transform of this function which is the impulse, so these 2 forms a Fourier transform pair. So delta t the Fourier transform is simply unity for - infinity less than or equals to that is for all frequencies - infinity less than equals to infinity, this form a Fourier transform this form a Fourier transform pair.

(Refer Slide Time: 33:27)

Against similarly, you can find the Fourier transform, the shifted impulse delta t - t0, correct. The shifted impulse of FT of delta t - t0 equals to - infinity to infinity delta t - t0 e power - j 2 Pi dt, once again this is your Phi t from the previous properties. So this is e to the power of - j 2 Pi Ft evaluated at equals to t0 that is e to the power of - j 2 Pi F Ft0. So delta t - t0 that is the shifted impulse is basically the Fourier transform pair is delta t - t0 is e to the power of - j 2 Pi

Ft and notice that this is well, of course we know this is the shifted impulse, this is your shifted impulse and this e to the power of $-j 2 \pi F_0 t$ in the frequency, remember this is in the frequency domain not the time domain, so this is a complex Sinusoid in the frequency domain, correct.

Usually we have the Sinusoid in the time domain which is e to the e power $-j 2 \pi F_0 t$, which is frequency F_0 which is a function of time at frequency F_0 . Now we have the analog in the frequency domain e power $-j 2 \pi F t_0$, alright. So this is a complex Sinusoid in the frequency domain this is defined for all frequencies - infinity to infinity less than equals to F less than equals to infinity. So this is a complex Sinusoid in the frequency domain.

So the shifted impulse $\delta(t - t_0)$ has basically the Fourier transform which is a complex Sinusoid in the frequency domain, alright. So basically we will have to stop this module here, we have looked at the modulation property, alright. The modulation is a very important; we said modulation is a very important step in any communication system, alright. And subsequently we looked at this very interesting and very fundamental function which is the unit impulse function which is also known as the direct delta function denoted by $\delta(t)$, looked at it is various properties and also the Fourier transform of $\delta(t)$ and $\delta(t - T_0)$, which is the shifted impulse or the shifted direct delta, alright. So let us stop here and continue with other aspects in the subsequent modules, thank you.
