**Definition of Entropy, Average Information/ Uncertainty of Source, Properties of Entropy**

Hello. Welcome to another module in this massive open online. So, in this module alright, let us start looking at a new topic that is entropy which is one of the most fundamental aspects of information theory, which we will going to define shortly. So, this is entropy.

(Refer Slide Time: 00:42)

The image shows a digital whiteboard with handwritten notes. At the top, there is a horizontal line. Below it, the equation  $I(s_i) = \log_2\left(\frac{1}{P_i}\right)$  is written in blue ink, followed by the word "bits". A blue arrow points from  $P_i$  in the denominator to the equation  $P_i = \Pr(s_i)$  written below it. Below this, two lines describe the limiting behavior of  $I(s_i)$  as  $P_i$  approaches 0 and 1. The first line shows  $I(s_i) \xrightarrow{\text{as } P_i \rightarrow 0} \infty$  in blue ink. The second line shows  $I(s_i) \xrightarrow{\text{as } P_i \rightarrow 1} 0$  in orange ink. The whiteboard interface includes a toolbar at the top with various drawing tools and a status bar at the bottom showing "11 / 66".

So, we have seen in our discussion that,  $I(s_i)$  is the information per symbol with the corresponding to source alphabet  $S$ .  $I$  is  $\log_2 1$  to the base  $\log_2 1$  over  $P_i$  to the base 2 bit is correct right. And well  $P_i$  we have seen this is nothing, but the probability of the symbol  $s_i$  and we have seen that  $I(s_i)$  this quantity tends to infinity as  $P_i \rightarrow 0$  the probability as base equally  $P_i$  tends to 0. And  $I(s_i)$  tends to 0 that is for certain events that is when the event occurs with probability 1.  $I(s_i)$  tends to 0 information tends to 0 alright. So, frequently occurring event have less information rare events have higher amount of information associated with them.

(Refer Slide Time: 02:14)

Average Information of source S is

$$I(S) = E\{I(s)\}$$
$$= \sum_{i=0}^{M-1} P_i I(s_i)$$

12 / 66

Now, the average information the average information of the source can now be defined as the average information of source S well average information of source S is simply the expected value this is I of S which is expected value of I of well expected value of I of S which is basically nothing, but well this is summation i equal to 0 summation i equal to 0 to m minus 1 log 2. So, this is  $P_i \log 2$  or let me write it this way. This is  $P_i$  times the information that probability of symbol i times the information associated with symbol i.

(Refer Slide Time: 03:33)

$H(S) = E\{I(s)\}$

$$= \sum_{i=0}^{M-1} P_i I(s_i)$$

$$H(S) = \sum_{i=0}^{M-1} P_i \log_2 \left( \frac{1}{P_i} \right)$$

Entropy of source S

$I(s_i)$

12 / 66

So, we are computing of weighted average. So, this is equal to  $P_i \log_2 \frac{1}{P_i}$ . And this quantity it is expected value of  $s$  this quantity is termed as  $H$  of  $S$ .  $H$  of  $S$  equals  $\sum P_i \log_2 \frac{1}{P_i}$ . This is termed as it is a fundamental quantity of information theory is termed as the entropy. This is termed as the entropy of sources.

(Refer Slide Time: 04:57)

So, this is termed as the entropy of source  $S$ . So, it is basically information of symbol  $i$  this is your information of symbol  $i$  weighted by the probability  $P_i$ , weighted by it is probability of occurrence. So, it is the expected value as a average information of the source which is obtained by weighing the information of each symbol  $S_i$  that is  $I(s_i)$  with it is probability  $P_i$  and summing over all the alphabets summing over the entire source alphabet, alright.

So, this quantity is termed as the entropy of the source and as we have said is a fundamental quantity in information theory. It can characterizes the average information per source average it characterizes. So, this characterizes entropy characterizes or quantifies average information content, average information of the source average information of the source as in the information average information per symbol one can also think of average information per symbol emitted by the source. Emitted or generated emitted or generated. This can also be thought of as entropy can also be thought of as average uncertainty.

(Refer Slide Time: 07:16)

It is the average the average uncertainty associated with the source. So, more uncertainty also implies basically more randomness or so more uncertainty.

So, more uncertainty more uncertainty implies more information. So, you can also be thought of as the average uncertainty right. So, this symbol what is uncertain about the next symbol that is going to be generated about the source all right. There is which means that there is greater uncertainty, which captures the fact that that is created information in the symbols generated by the source. If this if there is a greater certainty if we know for sure what the or if we show or if you know with great certainty what the next symbol that is generated by the source is going to be; that means, on an average there is less information in the symbols or less information content in the symbols that is generated by the source.

We are going to see this also of course, as we proceed through subsequent aspects or subsequent examples of entropy.

(Refer Slide Time: 09:10)

The image shows a handwritten derivation on a digital whiteboard. At the top, the entropy formula is written:  $H(S) = \sum_{i=0}^{M-1} P_i \log_2 \left( \frac{1}{P_i} \right)$ . Below this, a series of logical steps are shown in green ink. First, the probability range  $0 \leq P_i \leq 1$  is noted, which implies  $1 \leq \frac{1}{P_i} < \infty$ . This leads to a boxed statement  $\log_2 \left( \frac{1}{P_i} \right) \geq 0$ . Then, it follows that  $P_i \log_2 \left( \frac{1}{P_i} \right) \geq 0$  for each  $i$ . A blue arrow points from the summation in the entropy formula to the text 'sum of non-negative terms', which then points to the conclusion  $H(S) \geq 0$ . The whiteboard interface includes a toolbar at the top and a status bar at the bottom showing '14 / 65'.

$$H(S) = \sum_{i=0}^{M-1} P_i \log_2 \left( \frac{1}{P_i} \right)$$

$0 \leq P_i \leq 1$   
 $\Rightarrow 1 \leq \frac{1}{P_i} < \infty$   
 $\Rightarrow \log_2 \left( \frac{1}{P_i} \right) \geq 0$   
 $\Rightarrow P_i \log_2 \left( \frac{1}{P_i} \right) \geq 0$  for each  $i$

sum of non-negative terms  
 $\downarrow$   
 $H(S) \geq 0$

Now, let us start by looking at some simple properties of entropy, if you look at the definition of entropy which is  $P_i \log$  on or  $p$  an observed that well  $P_i$  greater than equal to 0 less than equal to 1 over  $P_i$  less than or equal to 1 this implies well one less than or equal to 1 over  $P_i$  less than. So,  $1$  over  $P_i$  is always basically greater than or equal to 1 which implies  $\log 1$  over  $P_i$  to the base 2 is greater than or equal to 0. Since  $1$  over  $P_i$  is greater than equal to 1. So,  $P_i$  is greater than equal to  $1 \log$  to the 2 to the base  $1$  over  $P_i$ .  $\log$  to the base 2  $1$  over  $p$  is greater than equal to 0. So,  $P_i$  is greater than equal to 0 correct  $\log 1$ , over  $P_i$  to the base 2 is greater than equal to 0, this implies both of these are non negative quantities.

(Refer Slide Time: 10:33)

A handwritten derivation on a whiteboard showing the steps to prove that entropy is non-negative. The text is written in blue and green ink. It starts with the inequality  $0 \leq p_i \leq 1$ , which implies  $1 \leq \frac{1}{p_i} < \infty$ . This leads to  $\log_2\left(\frac{1}{p_i}\right) \geq 0$ , which is boxed. Then, multiplying by  $p_i$  gives  $p_i \log_2\left(\frac{1}{p_i}\right) \geq 0$  for each  $i$ . A blue arrow points from the boxed equation to the conclusion  $H(S) \geq 0$ , which is labeled as the 'sum of non-negative terms'. Finally, the statement 'Entropy is non-negative' is written and underlined, followed by  $H(S) \geq 0$ .

$$0 \leq p_i \leq 1$$
$$\Rightarrow 1 \leq \frac{1}{p_i} < \infty$$
$$\Rightarrow \log_2\left(\frac{1}{p_i}\right) \geq 0$$
$$\Rightarrow p_i \log_2\left(\frac{1}{p_i}\right) \geq 0 \quad \text{for each } i$$

sum of non-negative terms  $\downarrow$

$$H(S) \geq 0$$

Entropy is non-negative

$$\underline{H(S) \geq 0}$$

So, therefore,  $p_i \log \frac{1}{p_i}$  to the base 2 is greater than or equal to 0 for each  $i$ . So, this is basically this entropy is the sum of non negative terms, implies  $H$  of  $S$  is also greater than or equal to 0. So, entropy is non negative correct. Entropy can be zero, but it cannot be negative. In fact, we will see examples where entropy is 0. So, entropy has to be greater than equal to. So, this also means that the information content of a source cannot be negative. It is non negative either 0 or greater than 0 entropy of a source the information content of a source has to be greater than or equal to 0.

(Refer Slide Time: 11:50)

A handwritten conclusion on a whiteboard. It repeats the inequality  $p_i \log_2\left(\frac{1}{p_i}\right) \geq 0$  for each  $i$  and the conclusion  $H(S) \geq 0$ . Below this, the statement 'Entropy is non-negative' is underlined, followed by  $H(S) \geq 0$ . A blue arrow points from this underlined statement to the final conclusion 'Information content of source  $\geq 0$ ', which is also underlined.

$$H(S) \geq 0 \Rightarrow p_i \log_2\left(\frac{1}{p_i}\right) \geq 0 \quad \text{for each } i$$

Entropy is non-negative

$$\underline{H(S) \geq 0}$$

Information content of source  $\geq 0$

So, this basically means that the information content, information content of source is greater than equal to 0.

(Refer Slide Time: 12:16)

Further, if  $P_i = 1$

$$P_i \log_2 \left( \frac{1}{P_i} \right) = 1 \cdot \log_2 \left( \frac{1}{1} \right)$$

$$= 0$$

$= 0$  For  $P_i = 1$

↙  $P_i = 0 ?$

$$P_i \log_2 \left( \frac{1}{P_i} \right) = \frac{\log_2 \left( \frac{1}{P_i} \right)}{\frac{1}{P_i}}$$

Further observe that if  $P_i$  equal to 1, then  $P_i$  log to the base 2 or  $P_i$  equal to 1 times log to the base 2 1 over 1 this is 0. So, this is equal to 0.

So, this quantity equals 0 for  $P_i$  well for  $P_i$  equal to 1. Now what happens if  $P_i$  equal to 0 what happens to this quantity  $P_i$  equals 0  $P_i$  equals 0, let us look at this quantity  $P_i$  log to the base 2, 1 over  $P_i$ , which is equal to I can write it as log to the base 2, 1 over log to the base 2 1 over  $P_i$  divided by 1 over  $P_i$ .

(Refer Slide Time: 13:34)

$$P_i = 0? \quad \log_2\left(\frac{1}{P_i}\right) = \frac{\log_2\left(\frac{1}{P_i}\right)}{\frac{1}{P_i}}$$

Numerator & Denominator  $\rightarrow \infty$  as  $P_i \rightarrow 0$

Now, you can see here that both the numerator that is if you look at this quantity here, numerator and the denominator tend to infinity as  $P_i$  tends to 0 as  $P_i$  tends to 0 both the numerator and denominator tend to infinity. So, this is undefined. So, this expression at 0 in that sense it is undefined.

So, let us look at the limit as  $P_i$  tends to 0. And naturally if both the numerator and denominator tend to infinity as  $P_i$  tends to 0, we can use the l'Hopital's rule right which is the rule in calculus to evaluate the limit. So, correct.

(Refer Slide Time: 14:29)

$$\lim_{P_i \rightarrow 0} \frac{\log_2\left(\frac{1}{P_i}\right)}{\left(\frac{1}{P_i}\right)} = \lim_{P_i \rightarrow 0} \frac{-\log_2 P_i}{\frac{1}{P_i}}$$

$\rightarrow \infty$  as  $P_i \rightarrow 0$

So, now let us calculate the limit of this as  $P_i$  tends to 0, that is  $\log$  the base to 1 over  $P_i$  which is equal to well, I will write the numerator as minus  $\log$  to the base 2  $P_i$  1 over  $P_i$  which is equal to.

(Refer Slide Time: 15:06)

The image shows a digital whiteboard with a toolbar at the top. The handwritten text on the board is as follows:

$$\lim_{P_i \rightarrow 0} \frac{\log_2 P_i}{\left(\frac{1}{P_i}\right)}$$

$$= \lim_{P_i \rightarrow 0} \frac{-\log_2 P_i}{\frac{1}{P_i}}$$

$$= \lim_{P_i \rightarrow 0} \frac{\frac{d}{dP_i} (-\log_2 P_i)}{\frac{d}{dP_i} \left(\frac{1}{P_i}\right)}$$

To the right of the second equation, the text "L'Hopital Rule" is written in red, with a red arrow pointing to the fraction.

Now, again I can differentiate this I can take the derivative of the numerator since it is ill defined on substitution of 0, I can take minus  $\log 2$  to the base  $P_i$ . I can differentiate the numerator and denominator differentiate the numerator and denominator with respect to  $P_i$ . This is termed as a L'Hospital's Rule which is basically from calculus to evaluate correct the limit of precise with such quantities which are ill defined.

(Refer Slide Time: 16:18)

$$\begin{aligned}
 &= \lim_{p_i \rightarrow 0} \frac{\frac{d}{dp_i}(-\log p_i \log_2 e)}{-\frac{1}{p_i^2}} \\
 &= \lim_{p_i \rightarrow 0} \left(-\frac{1}{p_i}\right) \cdot \log_2 e \cdot (-p_i^2) \\
 &= \lim_{p_i \rightarrow 0} p_i \log_2 e = 0.
 \end{aligned}$$

Now, if I substitute this that becomes limit  $p_i$  tends to 0, if you look at this that becomes well the numerator is well  $d$  by  $d$  minus  $\log p_i$  to the base 2. I can write this as  $p_i^2$  the base that is your traditional logarithm to the base  $e$ , to  $\log e$  to the base 2 divided by well I can differentiate with respect to  $p_i$  that gives me minus 1 over  $p_i$  square. And finally, differentiating the numerator, I get minus  $\log$  minus derivative of  $\log$  is 1 over  $p_i$  minus  $\log$  in to  $\log e$  to the base 2 into  $p_i$  square from the denominator will come to the numerator. So this is basically limit  $p_i$  tends to 0, well  $p_i$  into  $\log_2 p$  to the base 2 which is equal to 0. So, basically what we have established is if you look at this is limit that is.

(Refer Slide Time: 18:03)

$$\begin{aligned}
 &= \lim_{p_i \rightarrow 0} \left(-\frac{1}{p_i}\right) \cdot \log_2 e \cdot (-p_i^2) \\
 &= \lim_{p_i \rightarrow 0} p_i \log_2 e = 0.
 \end{aligned}$$

$$\lim_{p_i \rightarrow 0} p_i \log_2 \left(\frac{1}{p_i}\right) \rightarrow 0$$

$p_i \log_2 \left(\frac{1}{p_i}\right) = 0$  for  $p_i = 1$

Since we cannot directly substitute  $P_i$  equal to 0 into  $P_i \log_2 \frac{1}{P_i}$  limit,  $P_i \log_2 \frac{1}{P_i}$  tends to 0  $P_i$  log to the base 2  $\frac{1}{P_i}$  also tends to 0.

So, you can say. So, and also remember we have also seen before that  $P_i \log_2 \frac{1}{P_i}$  equals also equals 0 for certain events that is for  $P_i$  equal to 1. So, we have seen that for both the what you see is that as  $P_i$  tends to 0 all for  $P_i$  equal to 1 the average information that is  $P_i \log_2 \frac{1}{P_i}$  is basically 0 that is for both events which occur with probability one, and events which tend to occur with probabilities close to 0 or the rarest of the rare events which rarely occur which means that the probability of occurrence is close to 0 for both such events both types of such events the average information associated with 0. And this is this can be understood as follows that of course, as we have seen events which occur very frequently that is the probability close to one naturally the information associated with them is 0.

So, the average information associated with them is 0 as we have seen before, but what we have seen is that although information associated with the rare events which are probability close to 0 is very high, since they occur extremely infrequently the average information associated with them is also 0 all right. So,  $P_i \log_2 \frac{1}{P_i}$  is 0 when  $P_i$  equal to 1 or when  $P_i$  is also close to 0. So, that is an important point.

(Refer Slide Time: 20:19)

The image shows handwritten notes on a digital whiteboard. At the top, it says  $P_i \rightarrow 0$  and  $0 \log_2 \frac{1}{0}$ . Below this, a blue arrow points to  $= 0$ . To the right, it says  $P_i \log_2 \frac{1}{P_i} = 0$  for  $P_i = 1$ . In the middle, it says  $P_i \log_2 \frac{1}{P_i} \approx 0$ . Below this, it says "For both very common & very rare events". Two arrows point from this text to  $P_i \approx 1$  and  $P_i \approx 0$ .

So, this basically shows that this is basically equal to. So,  $1/p_i \log_2$  to the base 2 to the base. So, what we have seen is  $p_i$  intuitively this is close to 0 for both very common and very rare very common, and very common meaning,  $p_i$  approximately equal to 1, very rare meaning  $p_i$  approximately equal to 0. So, that is what we have, so all right.

So, in this module what we have seen is basically we have defined a very important quantity, which is the entropy all right which is basically the average information associated with each symbol of the source which is expected value of the information expected value of the information per symbol that is  $H$  of the source which denotes the average information that is associated per each symbol of the source. Which also said this characterizes the uncertainty associated with the source all right, which is also basically used to characterize or quantify the information content of a particular source and we have also seen that  $p_i \log_2 1/p_i$  is equal to 0 when  $p_i$  is 1 or  $p_i$  is very close to 0.

So, we will stop here and continue with other aspects in the subsequent modules.

Thank you very much.
