Laplace Transform – Partial Fraction Expansion with simple Poles and Poles with Multiplicity Greater than Unity, Laplace Transform of LTI Systems

Hello welcome to another module in this massive open online course all right. So, we are looking at the properties of the region of convergence of the Laplace transform. We will let us just continue this discussion if $x(t)$ is a 2 sided signal.

(Refer Slide Time: 00:26)

On the other hand, if $x(t)$ is a 2 sided signal which implies $x(t)$ is non-zero for entire range; that is minus infinity less than t less than infinity, that is it looks something like it is a 2 sided signal. This is the time axis and this is $x(t)$ is non-zero.

(Refer Slide Time: 01:24)

ROC of the Form
 $\sigma_1 < \text{Re}\{s\} < \sigma_2$
 $\sigma_1, \sigma_2 = \text{Real Parts of Two poles of } X(s).$

Thus, ROC = vertical strip
between lines $\text{Re}\{s\} = \sigma_1,$
 $\text{Re}\{s\} = \sigma_2$

Then the ROC is of the form $\sigma_1 < \text{real part of } s < \sigma_2$, where σ_1 comma σ_2 are the real parts of two poles of X of s , where σ_1 σ_2 are the real parts of two poles of X of s . Thus the ROC is the vertical strip. This ROC equal to vertical strip between the lines, real part of s equals σ_1 comma real part of s equals σ_2 . So, the ROC is basically a vertical strip and this, you can check this as follows; that is basically if you look at this.

(Refer Slide Time: 02:47)

Thus, ROC = vertical strip
between lines $\text{Re}\{s\} = \sigma_1,$
 $\text{Re}\{s\} = \sigma_2$ ROC.

Again let me just draw this. So, you have sigma, you have j omega, you have your sigma 1, you have your sigma 2. The real parts between these two poles, and therefore, the ROC will be this vertical strip. This is your ROC.

For instance, let us take again a simple example; this I think is best illustrated using an example.

(Refer Slide Time: 03:17)

ex: $x(t) = -e^{2t}u(-t) + e^{-3t}u(t)$

2 sided signal.

$X(s) = \frac{1}{s-2} + \frac{1}{s+3}$

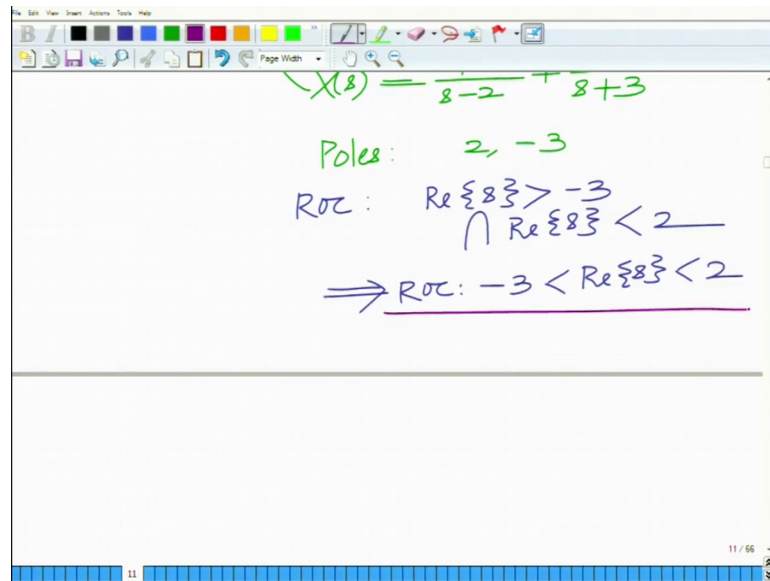

Poles: 2, -3

ROC: $\text{Re}\{s\} > -3$
 $\cap \text{Re}\{s\} < 2$

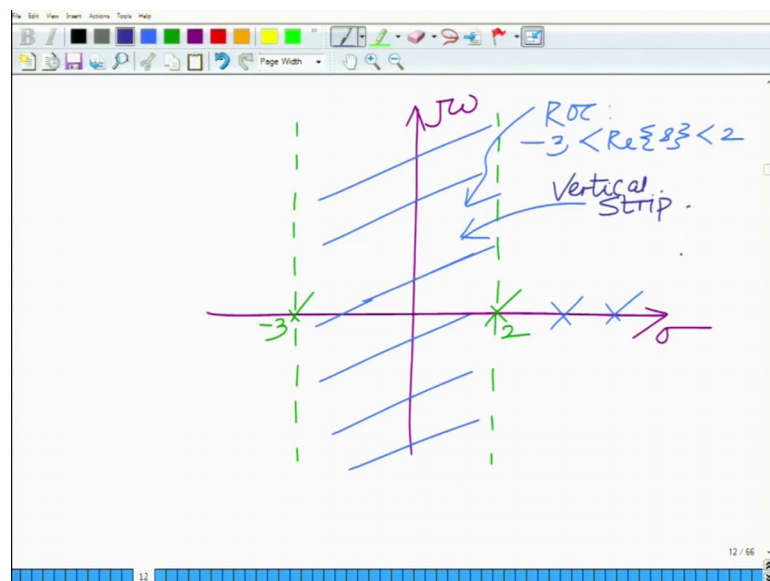

For instance if you take xt equals minus e raise to 2 t, you mind u u minus t minus e raise to 2 t u minus t correct, and plus e raise to minus 3 t u t, then the Laplace transform. Now look at this, this is a 2 sided signal. So, this you can click, this you can check, because u minus t is non 0 for t less than 0, u t is non 0 for t greater than 0.

So, this is a 2 sided signal this and the Laplace transform Xs. You can verify that is given as 1 over s minus 2 plus 1 over s plus 3, and the poles are 2 comma minus 3, and the ROC will be. Basically you can see it is the intersection of the ROCs of the both signals; that is real part of s greater than minus 3 intersection real part of s less than 2; that is the intersection, and which implies the ROC is basically minus 3 less than real part of s less than.

(Refer Slide Time: 04:58)

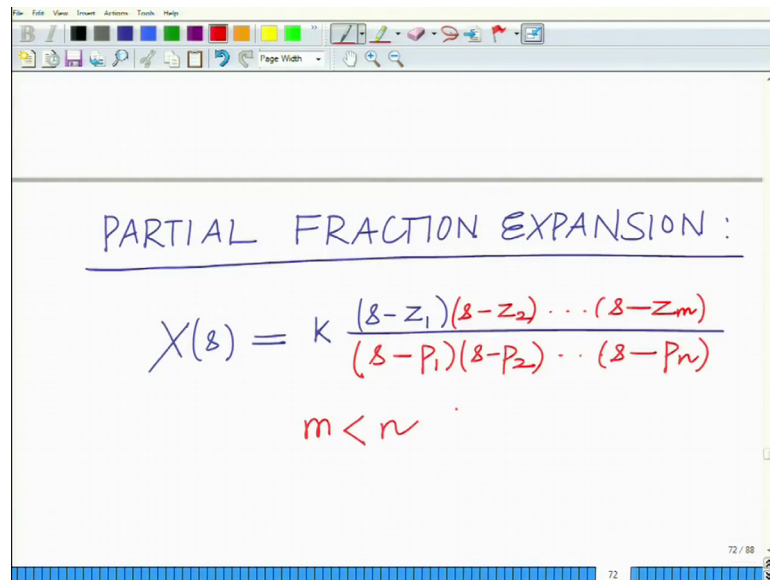

(Refer Slide Time: 05:13)

So, this is basically your final ROC and therefore, it includes the strip between minus 3 and 2, and this can be simply illustrated as follows; this is sigma, this is j omega and you have minus 3 sigma equals minus 3. Here this is one pole and you have sigma equals 2. Here this is another pole, this is the other pole and ROC is the strip between this two. ROC is minus 3 less than real part of s less than 2, and any other poles can only lie outside the ROC. So, you can have poles which are outside only, outside the ROC ok.

And this is basically a vertical strip. So, this is the ROC; that is σ_1 less than σ less than σ_2 . This is basically the ROC, and the ROC in this example is $\sigma < -3$ less than real part of s less than, and so let us look at the partial fraction expansion.

(Refer Slide Time: 06:51)

PARTIAL FRACTION EXPANSION :

$$X(s) = K \frac{(s-z_1)(s-z_2) \dots (s-z_m)}{(s-p_1)(s-p_2) \dots (s-p_n)}$$

$m < n$

The partial fraction of expansion that is, if X we have X s equals some constant K times s minus Z_1 times s minus Z_2 into s minus Z_m divided by s minus P_1 ; that is $Z_1 Z_2 Z_m$ are the zeros s minus P_2 into s minus P_n , where $m < P_1 < P_2 < P_n$ are the poles and m is less than, m is less than. And remember when m is less than n , this is known as a proper rational expression or the proper rational function.

(Refer Slide Time: 08:05)

$n=2$
 $m < n$
 \Rightarrow Proper Rational Function.

$$= \frac{4(s + \frac{3}{4})}{2(s+2)(s+1)}$$
$$= \frac{2(s + \frac{3}{4})}{(s+2)(s+1)}$$

$z_1 = -\frac{3}{4}$: zero.
 $p_1 = -2, p_2 = -1$: Poles.

ROC cannot include poles $= -2, -1$.

PROPERTIES OF ROC :

So, if it is a proper rational function, I can express, that is implies this is a proper rational function. If this is a proper rational function then I can express X s as the sum, and simple pole case. We are assuming all the poles are distinct; that is we have simple poles.

(Refer Slide Time: 08:40)

$m < n \Rightarrow$ Proper Rational Function

Simple poles \Rightarrow All poles are Distinct
 $p_i \neq p_j$

$$X(s) = \frac{C_1}{s-p_1} + \frac{C_2}{s-p_2} + \dots + \frac{C_n}{s-p_n}$$

Partial Fraction Expansion.

$$C_k = (s-p_k)X(s)|_{s=p_k}$$

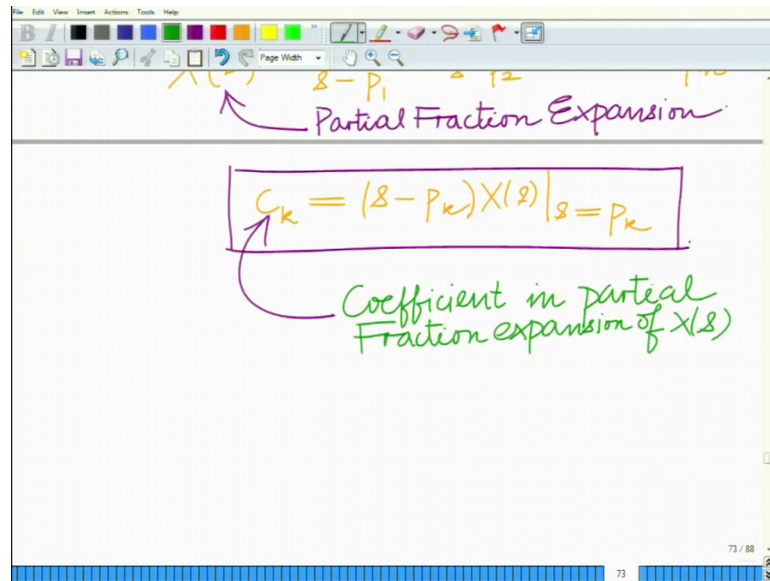

That is no two poles are such that P_i equals P_j ; that is all poles P_i not equals P_j .

So, we have all the poles are distinct for. So, for the simple pole case, all poles are simple, which means all poles are basically distinct, and for that scenario Xs can be expressed as C_1 by s minus P_1 plus C_2 by s minus P_2 plus C_n by s minus P_n , where

the coefficient C_k is given as $s - p_k$ times $X(s)$ evaluated at $s = p_k$. So, this is the partial fraction expansion of $X(s)$, and C_k is the coefficient k th coefficient all right.

In the partial fraction this is a coefficient in the partial fraction expansion of $X(s)$. This is a coefficient in the partial fraction expansion of $X(s)$.

(Refer Slide Time: 10:23)

So, far; so, what we have, is a partial fraction expansion for the case where m is less than n all right; that is the degree of the numerator polynomial is strictly lower than the degree of the denominator polynomial. This is a proper rational function, $X(s)$ is a proper rational function all right.

In this case we express using its partial fraction expansion; that is the sum C_1 by $s - p_1$ plus C_2 by $s - p_2$ so on, and C_k , the coefficient of the k th term is given as $s - p_k$ times $X(s)$ evaluated at the pole $s = p_k$. And all the poles are assumed to be simple; that is there are no repeated poles. So, all the poles are distinct p_i not equals p_j ok.

(Refer Slide Time: 11:40)

Coefficient in partial Fraction expansion of $X(s)$

MULTIPLE POLE :

$X(s)$ in denominator has a factor of form $(s - P_i)^r$

Pole P_i has multiplicity $= r$

73 / 88

Now, for the multiple pole case, now for the multiple pole case $X(s)$ in denominator has a factor of form. It has a factor of form s minus P_i raise to the power of r and then in this scenario, we say that the pole P_i has a multiplicity of r . So, this implies pole P_i , pole P_i has multiplicity equal to r .

(Refer Slide Time: 12:51)

Pole P_i has multiplicity $= r$

$X(s)$ will have terms of form

$$\frac{\lambda_1}{s - P_i} + \frac{\lambda_2}{(s - P_i)^2} + \dots + \frac{\lambda_r}{(s - P_i)^r}$$

Terms for pole P_i

74 / 88

And therefore, $X(s)$ will have terms of the form the partial fraction expansion of $X(s)$ will have terms of the form. We will have terms of the form λ_1 divided by s minus P_i

plus λ_2 divided by $s - p_i$ square plus λ_r divided by $s - p_i$ raised to the power of r .

So, these are the terms corresponding to $s - p_i$ corresponding. These are the terms corresponding to pole p_i and you will have the rest of the terms corresponding to other poles, terms for pole p_i which has multiplicity r . So, these are the terms. So, there will be r terms corresponding to the pole p_i all right. λ_1 by $s - p_i$, λ_2 by $s - p_i$ square so on up to λ_r divided by $s - p_i$ raised to the power of r , where r is a multiple of the multiplicity of the pole here, and the coefficient λ_k , λ_{r-k} is evaluated as follows

(Refer Slide Time: 14:18)

The image shows a whiteboard with the following content:

$X(s)$ will have terms of form

$$\frac{\lambda_1}{s - p_i} + \frac{\lambda_2}{(s - p_i)^2} + \dots + \frac{\lambda_r}{(s - p_i)^r}$$

Terms for pole p_i

$$\lambda_{r-k} = \frac{1}{k!} \frac{d^k}{ds^k} ((s - p_i)^r X(s)) \Big|_{s=p_i}$$

74 / 88

We have the expression for λ_{r-k} that will be equal to $1/k!$. So, this expression will be equal to $1/k!$ d^k raised to power k $s - p_i$ to the power raised to the power of r into $X(s)$ evaluated at $s = p_i$. So, this λ_{r-k} . Let me just write it again. Once again clearly $\lambda_{r-k} = 1/k!$ terms be to the d^k to the $s - p_i$ raised to the power of r $X(s)$ evaluated at $s = p_i$ evaluated at $s = p_i$ ok.

(Refer Slide Time: 15:48)

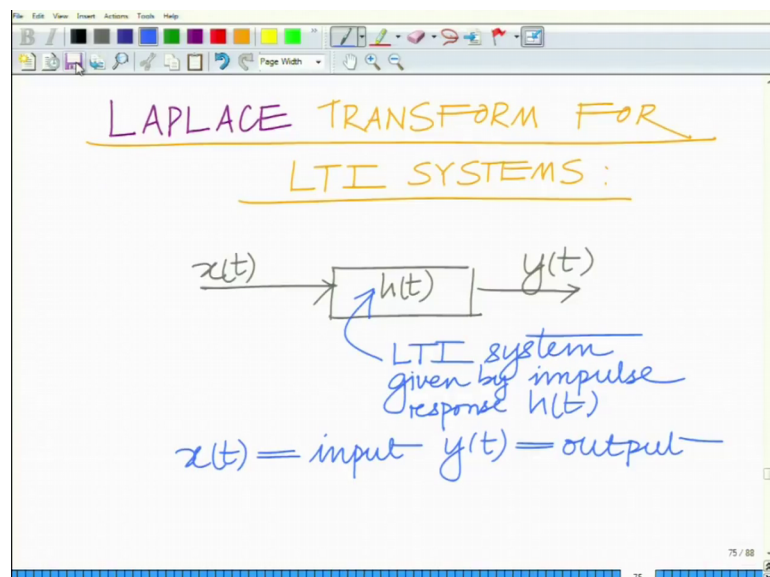

The slide shows a handwritten formula for the coefficient in the partial fraction expansion of $X(s)$ for a pole p_i . The formula is:

$$A_{r-k} = \frac{1}{k!} \left. \frac{d^k}{ds^k} ((s-p_i)^r X(s)) \right|_{s=p_i}$$

Below the formula, it is noted that this is the "Coefficient in PF expansion of $X(s)$ ". Above the formula, the text "Terms for pole p_i " is written. The slide also shows a toolbar at the top and a page number "74" at the bottom right.

So, this is basically the expression coefficient of. Remember coefficient in the partial fraction expansion, coefficient in partial fraction expansion of $X(s)$. This is the coefficient in the partial fraction expansion of the rational function, the rational for $X(s)$ which is the rational function of s only. So, that takes care of various scenarios; that is when you have simple poles as well as multiple poles.

(Refer Slide Time: 16:37)

Now, let us look at the Laplace transform properties for LTI systems; that is the next aspect, the Laplace transform and its application for the for LTI systems. So, let us look

at Laplace transform for LTI systems. Now for an LTI system, consider an LTI system given by impulse response $h(t)$. So, this is LTI system $x(t)$, $x(t)$ equals the input and $y(t)$ equals the output of the LTI system.

Then we have, we know that the output $y(t)$ of an LTI system is a convolution of the input $x(t)$ with the impulse response $h(t)$ of the LTI system. Therefore, the output impulse response. Remember convolution in the time domain is a product in the transform domain, there is a Laplace domain. Therefore, since we have $y(t)$ equals $x(t)$ convolved with $h(t)$.

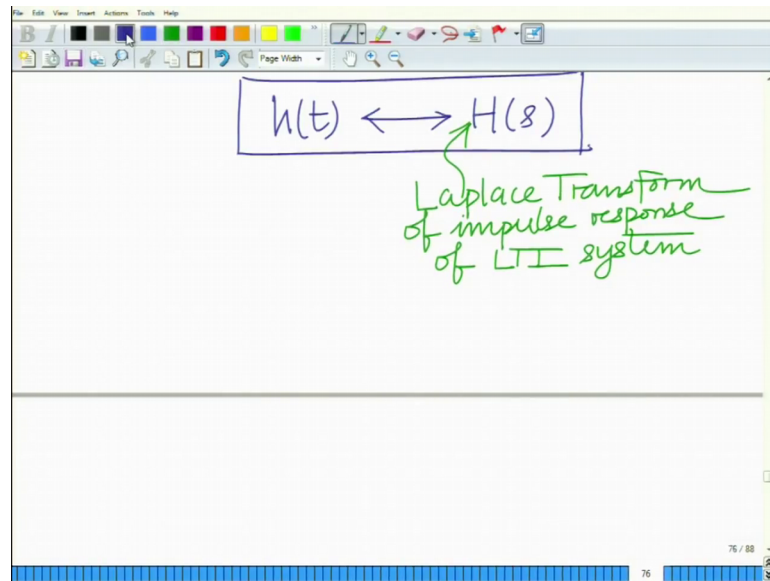

(Refer Slide Time: 18:26)

The image shows a whiteboard with handwritten mathematical equations and text. At the top, it says $x(t) = \text{input}$ and $y(t) = \text{output}$. Below this, it states $y(t) = x(t) * h(t)$, where $*$ is convolution, and $h(t)$ is the impulse response. This is followed by the Laplace transform equation $\Rightarrow Y(s) = X(s)H(s)$. A horizontal line separates this from the next part, which shows $\Rightarrow H(s) = \frac{Y(s)}{X(s)}$ enclosed in a box. An arrow points from the text "Transfer Function of system." below to the $H(s)$ in the box. The whiteboard also has a toolbar at the top and a page number "76 / 88" at the bottom right.

Remember this is your convolution and therefore, when we take the transform, the Laplace transform $Y(s)$ will be the product of the Laplace transforms of $X(s)$ term $H(s)$.

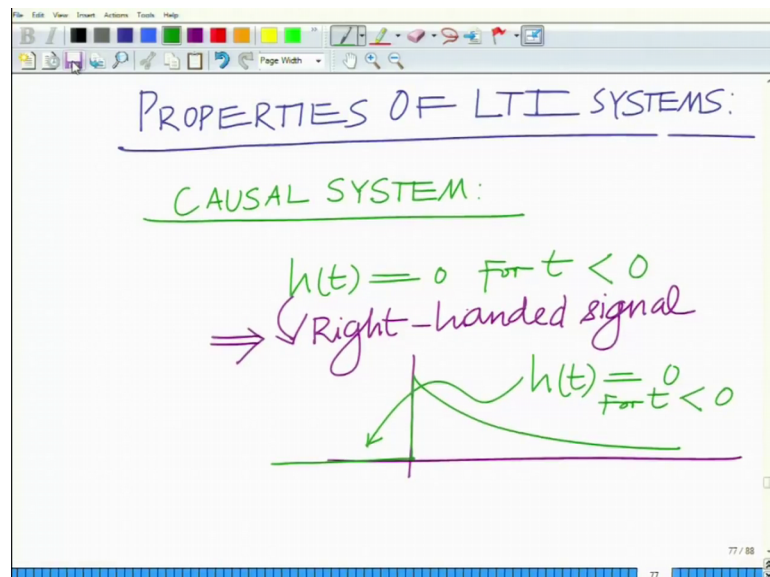

And. In fact, this also implies this, implies that also, implies that $H(s)$ equals $Y(s)$ divided by $X(s)$ and $H(s)$. This quantity is known as. This is a very important role in analysis of LTI systems. This is known as the transfer function, this is known as the transfer function, this is known as the transfer function of the system. So, $H(s)$ which is the Laplace transform of the impulse response. Remember $H(s)$ is the Laplace transform of the impulse response $h(t)$. This is known as the transfer function, and this characterizes, this is a fundamental aspect property of the system, it characterizes the behavior of this LTI system in a very fundamental fashion ok.

(Refer Slide Time: 20:00)

So, remember $h(t)$ has Laplace transform. So, $H(s)$ is the Laplace transform of the impulse response. So, this is the Laplace transform of the impulse response of the LTI system under consideration further. Now let us look at other properties of the LTI systems and from the perspective of the Laplace transform.

(Refer Slide Time: 20:53)

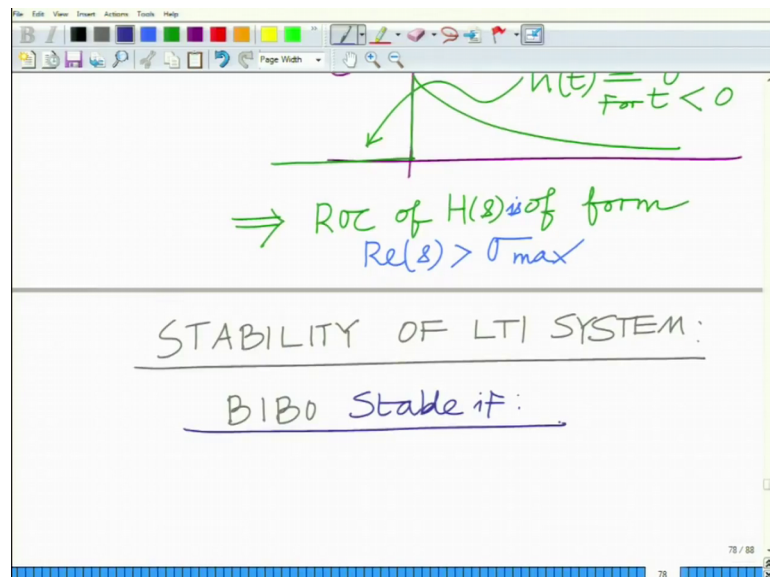

So, other properties of the LTI systems. Let us look at some other properties of the LTI systems. Now let us in particular, let us look at causality. Now for a causal system, remember we have $h(t) = 0$ for $t < 0$, which implies basically if you look at

this, this basically implies that $h(t)$ is a right handed signal. This basically implies $h(t)$ is a. Remember we have $h(t)$ of the form correct, we have $h(t)$ equal to 0 correct $h(t)$ equal to 0, for the impulse response has to be 0 for t less than 0 correct; that is the property of the causal, that is the property of the causal, that is the property of the causality a system that is $h(t)$ equals 0 for t less than 0, which implies $h(t)$ is a right handed signal, which implies the ROC of $h(t)$.

Now, from the properties of the ROC. Therefore, in the Laplace transform $H(s)$ must have ROC, which is of the form real part of s is greater than the σ_{max} .

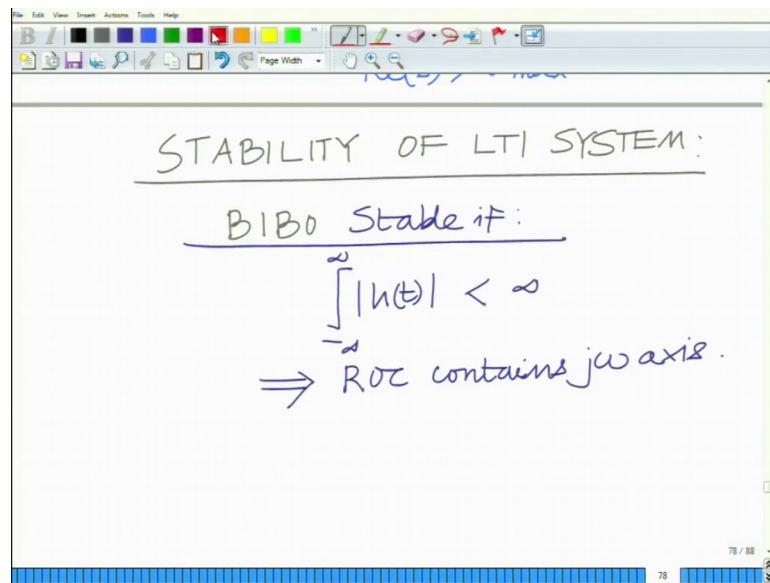

(Refer Slide Time: 22:52)

So, the ROC this implies in the ROC of $H(s)$ is a form, is a form. The real part of s is greater than σ_{max} . So, remember this follows from the properties of the ROC; that is since $h(t)$ is a causal system, if the LTI system is a causal system, it must be the case that the impulse response is non-zero for t less than 0, which is implies that it is a right handed signal, and therefore, the ROC of $H(s)$ which is impulse response of $h(t)$, which is the Laplace transform of $h(t)$ must be of the form, real part of s greater than σ_{max} ok.

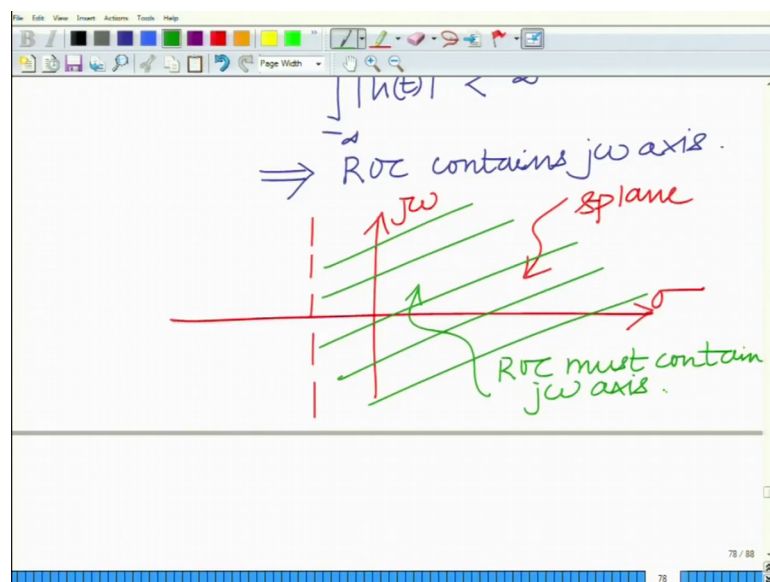

Now, let us look at stability of the LTI system. Now let us look at the stability of the LTI system. Now it is BIBO stable; remember bounded input bounded output stable.

(Refer Slide Time: 24:28)

If integral minus infinity to infinity magnitude h of t less than infinity. This implies that ROC contains the $j\omega$ axis; that is if you look at the s plane y axis is the $j\omega$. This is the. So, this is basically your s plane.

(Refer Slide Time: 24:56)

Now, whatever is ROC must contain the $j\omega$ plane. If the system is stable ROC must contain the $j\omega$ axis; that is this can be seen as follows.

(Refer Slide Time: 25:42)

The image shows a whiteboard with handwritten mathematical derivations. At the top, there is a note: "ROC must contain jw axis." with a diagram of a vertical line on the real axis and a shaded region to its left. Below this, the derivation starts with $s = j\omega$ and the equation $|H(j\omega)| = \left| \int_{-\infty}^{\infty} h(t) e^{-j\omega t} dt \right|$. This is followed by an inequality: $\leq \int_{-\infty}^{\infty} |h(t)| \frac{|e^{-j\omega t}|}{1} dt$. The final result is $= \int_{-\infty}^{\infty} |h(t)| dt \leftarrow \infty$, with the word "Finite" written in red below the integral.

If you look at magnitude of H of j omega; that is equal to integral minus infinity to infinity h of t e raise to minus; that is if you substitute s equals j omega magnitude of H of j omega is integral minus infinity to infinity h of t e raise to power minus j omega t dt , which is less than. That is a magnitude of the integral is less than or equal to the integral of the magnitude, which is less than or equal to. Therefore, integral h t integral e power minus j omega t dt .

But magnitude of e power raise to minus j omega t is 1 which means this is equal to integral e power minus minus infinity to infinity h of t dt . So, magnitude of h of j omega is a less than or equal to this, which means. Therefore, if this is finite, if this quantity is finite which implies, if this is finite implies, if this quantity, if integral magnitude integral minus infinity to infinity magnitude h t dt is finite, this implies

(Refer Slide Time: 27:12)

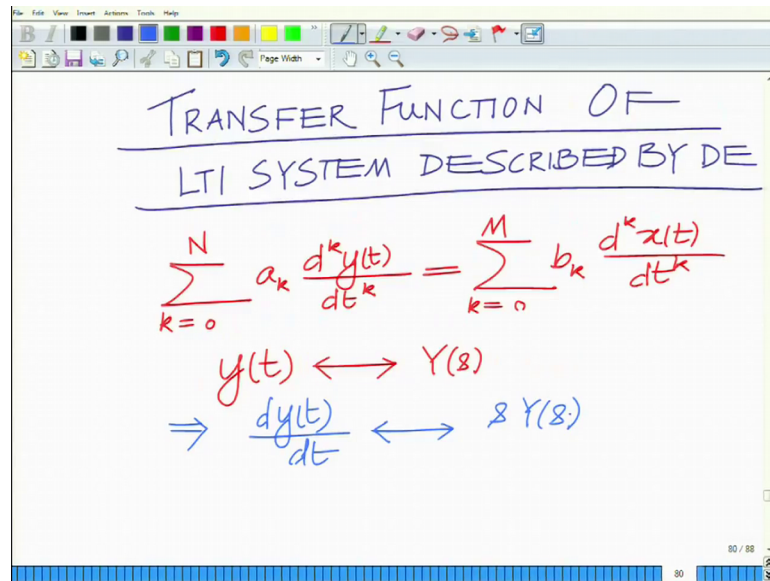

The image shows a whiteboard with handwritten mathematical derivations. The first line is $\leq \int_{-\infty}^{\infty} |h(t)| |e^{-j\omega t}| dt$. The second line is $= \int_{-\infty}^{\infty} |h(t)| dt < \infty$. Below the second line, the word "Finite" is written in red. The third line is $\Rightarrow H(j\omega) = \text{Finite} < \infty$. The fourth line is $\Rightarrow j\omega \in \text{ROC}$. The whiteboard has a toolbar at the top and a status bar at the bottom showing "79 / 88".

$H(j\omega)$ equals for finite quantity less than infinity which implies $j\omega$ is an element of $j\omega$ belongs to the ROC.

So, argument is the following; that is $H(j\omega)$ is strictly less than or equal to integral from minus infinity to infinity of $|h(t)| dt$, which is a finite quantity. Therefore, the magnitude of $H(j\omega)$ must be a finite quantity, which implies the Laplace transform must converge for $s = j\omega$, which implies that $j\omega$ belongs to the ROC of the Laplace transform. So, $j\omega \in \text{ROC}$ of the Laplace transform that is $H(s)$.

And finally, Laplace transform; that is a transfer function of the LTI system described by the differential equation.

(Refer Slide Time: 28:25)

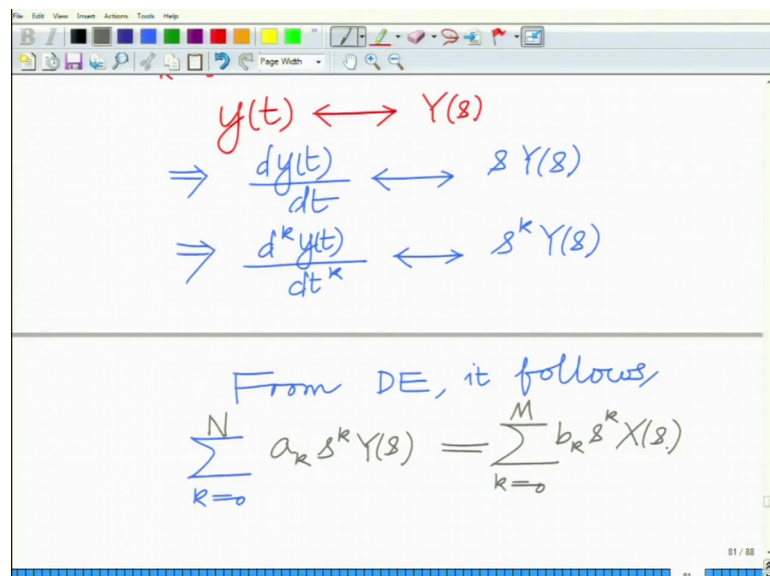

TRANSFER FUNCTION OF
LTI SYSTEM DESCRIBED BY DE

$$\sum_{k=0}^N a_k \frac{d^k y(t)}{dt^k} = \sum_{k=0}^M b_k \frac{d^k x(t)}{dt^k}$$
$$y(t) \longleftrightarrow Y(s)$$
$$\Rightarrow \frac{dy(t)}{dt} \longleftrightarrow s Y(s)$$

We have the transfer function of the LTI system described by the differential equation, described by a differential equation; that is I have sum k equals 0 to N a_k d raised to k y over dt^k ; that is equal to sum k raised to 0 to M b_k d raised to k x over dt^k , and d k d to the k x over dt^k .

Now, we know from the properties of the Laplace transform that $y(t)$ has Laplace transform $Y(s)$ implies. So, $y(t)$ implies d raised to k y over dt^k . Remember d y over dt has Laplace transform $s Y(s)$. In fact, this implies progressing this way.

(Refer Slide Time: 30:32)

$$y(t) \longleftrightarrow Y(s)$$
$$\Rightarrow \frac{dy(t)}{dt} \longleftrightarrow s Y(s)$$
$$\Rightarrow \frac{d^k y(t)}{dt^k} \longleftrightarrow s^k Y(s)$$

From DE, it follows

$$\sum_{k=0}^N a_k s^k Y(s) = \sum_{k=0}^M b_k s^k X(s)$$

We can show, one can show the d raise to k y t over dt k or for that matter d raise to k yt or dt k has Laplace transform s to the power s raise to k Ys.

Similarly, d raise to k d raise to k xt dt over dt k all right. The k th order derivative of the signal xt with respect to time, has a Laplace transform s to the power of k X s. So, substituting this we have. So, from the differential equation it follows, it follows that we have summation k equal to 0 to N a k s k s raise to k Ys equals summation k equal to 0 to M b k s raise to k X s.

(Refer Slide Time: 32:03)

$$\sum_{k=0}^N a_k s^k Y(s) = \sum_{k=0}^M b_k s^k X(s)$$

$$H(s) = \frac{Y(s)}{X(s)} = \frac{\sum_{k=0}^M b_k s^k}{\sum_{k=0}^N a_k s^k}$$

Transfer function of system

Rational Function

So, implies taking Ys common on the left Xs common on the right.

So, Ys by X s, if you look at this. This is equal to summation k equals 0 to M b raise to k x k s k divided by k equal to 0 to N a raise to k a k s raise to k and this is a transfer function. In fact, let me, we remember we said H s is defined as the impulse response that is the Laplace transform of the output divided by the Laplace transform the input. So, this is the transfer function of the system. This is the transfer function of the system, and remember this is a rational function. You can clearly see this is a rational, then you can clearly see that this is a rational function ok. So, all right. So, basically that completes our description of the definition, and the properties of the Laplace transform.

So, for, with this what we have done is, we have completed our discussion of the definition, definition of the ROC properties of the ROC, some of the properties of the

Laplace transform and the description of the properties of the Laplace transform with LTI, or with respect to LTI systems and several other aspects. So, this completes our discussion of the theory, behind the theory and applications theory, applications and the properties of the Laplace transform. And in the subsequent modules, we look at some of the examples related to Laplace transform solving problems, involving Laplace transform as it applies to the principles of signals and systems all right. So, we will stop here.

Thank you very much.
