Properties of z-Transform – Convolution, Inverse z-Transform through Partial Fractions, Properties of ROC

Hello, welcome to another module in this massive open online course. We are looking at the Z transform with properties and applications; let us continue this discussion today. Let us look at the convolution right, how to implement or what is a property of the Z transform with respect to the convolution operation. So, start by looking at convolution.

(Refer Slide Time: 00:33)

CONVOLUTION:

$$x_1(n) \leftrightarrow X_1(z)$$
$$x_2(n) \leftrightarrow X_2(z)$$
$$y(n) = x_1(n) * x_2(n)$$
$$y(n) = \sum_{m=-\infty}^{\infty} x_1(m) x_2(n-m)$$

Remember the convolution of two discrete time signals can be defined; that is let's say we have two discrete time signals $x_1(n]$ which has Z transform $X_1(z]$, and we have another signal $x_2(n]$ which has Z transform $X_2(z]$.

What can we say about $y(n]$, which is the convolution of $x_1(n]$ and $x_2(n]$; that is this is equal to summation, that is $y(n]$ equals summation m equals minus infinity to infinity $x_1(n]$ into or $x_1(m]$ rather into $x_2(n - m]$.

(Refer Slide Time: 01:53)

$$y[n] = \sum_{m=-\infty}^{\infty} x_1[m] x_2[n-m]$$
$$\Uparrow$$
$$Y(z) = \sum_{n=-\infty}^{\infty} y[n] z^{-n}$$

$$= \sum_{n=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} x_1[m] x_2[n-m] z^{-n}$$

$\xrightarrow{\text{y[n]}}$

Now we have the Z transform of y n is Y z which is given as summation n equals minus infinity to infinity y n z raised to minus n. This is the Z transform of the sequence y n which is summation from minus infinity to infinity y n z raised to minus n.

We want to find out what is the Z transform of y n, when y n is the convolution; that is convolution of two signals discrete time signals x 1 n and x 2 n, and therefore, now substitute the expression for y n from above. This is the expression for y n correct, and substitute the expression for y n from above. So, I have summation, we just write it clearly through this is equal to summation n equals minus infinity to infinity summation m equals minus infinity to infinity x 1 m x 2 n minus m z raised to minus m. So, this part, if you remember this part is y of n. So, summation n equals minus infinity to infinity y of n z raised to minus n. Now I am going to interchange the order of summation.

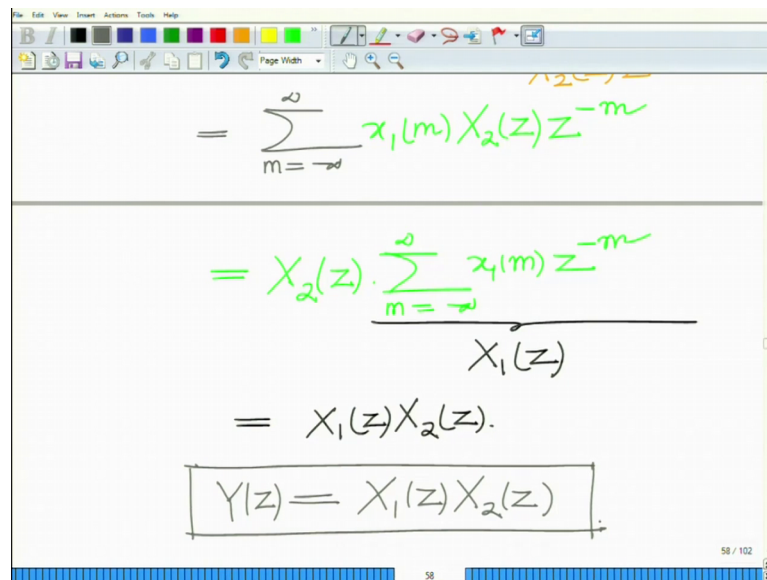

(Refer Slide Time: 03:27)

$$\begin{aligned}
 & n = -\infty \quad m = -\infty \\
 & \text{interchanging order of sum} \\
 & = \sum_{m=-\infty}^{\infty} x_1(m) \sum_{n=-\infty}^{\infty} x_2(n-m) z^{-n} \\
 & \quad \quad \quad \text{Z Transform of } x_2(m) \\
 & \quad \quad \quad \text{delayed by } m \\
 & \quad \quad \quad = X_2(z) z^{-m} \\
 & = \sum_{m=-\infty}^{\infty} x_1(m) X_2(z) z^{-m}
 \end{aligned}$$

So, I am going to write first m equals minus infinity to infinity \times 1 of m summation n equals minus infinity to infinity \times 2 of n minus m z raised to minus n . So, this is basically by interchanging the order of summation, interchanging the order of the sum and.

Now, you can see, this is the Z transform of x_2 ; that is x_2 n minus m that is x_2 delayed by m . So, this is Z transform x_2 n delayed by m , and therefore, this is nothing, but X_2 z into z raised to minus m and therefore, I can now write this as summation m equals minus infinity to infinity \times 1 \times X_2 z into z raised to minus m . Now the x to z comes out common.

(Refer Slide Time: 05:06)

$$\begin{aligned} &= \sum_{m=-\infty}^{\infty} x_1(m) X_2(z) z^{-m} \\ &= X_2(z) \cdot \underbrace{\sum_{m=-\infty}^{\infty} x_1(m) z^{-m}}_{X_1(z)} \\ &= X_1(z) X_2(z). \end{aligned}$$

$$Y(z) = X_1(z) X_2(z)$$

So, this is $X_2(z)$ summation m equals minus infinity to infinity $x_1(m)$ into z raised to minus m , and this you can clearly see, this is $X_1(z)$.

So, this is basically the product of the Z transforms $X_1(z)$ into $X_2(z)$. So, what we have here, is basically $Y(z)$ equals $X_1(z) X_2(z)$. So, the Z transform of the convolution of two signals is basically the product of their Z transforms, and this is similar to what we have seen in the Laplace transform. This is when you convolve two signals in the time domain in the transform domain. There are Laplace transforms are multiplied, there is a Laplace transform of the convolution of two signals, is basically the product of the individual Laplace transforms. Since they are similar to the Laplace transform this property gives us a convenient way to implement convolution, because convolution is typically fairly intricate to evaluate.

So, one can, rather one can otherwise as a trick evaluate the Z transforms of the signal multiply the Z transforms, and take the inverse Z transform to evaluate the convolution. So, this is an interesting property basically which.

(Refer Slide Time: 09:36)

The slide shows a handwritten derivation of the convolution theorem in the Z-transform domain. At the top, there is a partial equation: $= X_2(z) \cdot \sum_{m=-\infty}^{\infty} X_1(z) z^{-m}$. Below this, it is simplified to $= X_1(z) X_2(z)$. A boxed equation states $Y(z) = X_1(z) X_2(z)$. A blue arrow points from this boxed equation to the text: "convolution in time = Multiplication in Z Transform Domain". The slide is from a presentation, with a toolbar at the top and a footer showing "58 / 102".

Says that convolution in time, this multiplication in the Z transform domain. So, this can convert two signals; the Z transform resulting signal is basically the multiplication of the Z transforms of the signals being convolved. Let us now look at techniques to evaluate the inverse Z transform and similar to the inverse Laplace transform one can consider, one of the simplest techniques. So, there is by partial fraction expansion ok.

(Refer Slide Time: 07:22)

The slide is titled "INVERSE Z-TRANSFORM :". It shows the equation $X(z) = \sum_{n=-\infty}^{\infty} x(n) z^{-n}$. A blue arrow points from this equation to the text: "Express X(z) as a power series." Below this, it states $x(n) = \text{coefficient of } z^{-n}$. The slide is from a presentation, with a toolbar at the top and a footer showing "59 / 102".

So, let us say we have Xz equals summation n equals minus infinity to infinity $xn z$ raised to power of minus n . Now let $X z$. Now one thing we can do is, the simplest thing

you can do is, express Xz as a power series, simplest way to evaluate the Z transform is to express Xz as a power series. Now once you express Xz as a power series x_m is nothing, but the coefficient of z raised to minus n . So, that is one simple way to find the Z transform. So, x_n .

So, once you express Xz as a power series, realize that x_n is the coefficient of z raised to minus n . Now let us look at another technique that is. So, we can call this as the power series technique.

(Refer Slide Time: 09:06)

The image shows a whiteboard with handwritten mathematical notes. At the top, the Z-transform is defined as $X(z) = \sum_{n=-\infty}^{\infty} x(n)z^{-n}$. An arrow points from this equation to the text "Express $X(z)$ as a power series." Below this, it states " $x(n)$ = coefficient of z^{-n} ". The next section is titled "PARTIAL FRACTIONS:" in green. It shows the equation $X(z) = \frac{N(z)}{D(z)}$ labeled as a "Rational Function of Z ". This is then expanded to $= k \frac{(z-z_1)(z-z_2)\dots(z-z_m)}{(z-p_1)(z-p_2)\dots(z-p_n)}$.

Let us look at another technique that is a partial fraction expansion. So, basically you have, let us say a Z is a rational function; that is in Z divided by Dz , that is this is a rational function of Z , this is a rational function of Z which I can write as some constant k times Z minus Z_1 Z minus Z_2 Z minus Z_m divided by Z minus P_1 Z minus P_2 Z minus P_n .

(Refer Slide Time: 10:20)

$$\frac{z_1, z_2, \dots, z_m}{\text{zeros} - m}$$
$$\frac{p_1, p_2, \dots, p_n}{\text{poles} - n}$$

$n \geq m$

Assume all poles are simple
 \Rightarrow No Repeated Poles.

Now, we know that Z_1, Z_2, \dots, Z_m are the zeros that is denominator roots of the numerator polynomial Z s are the zeros, and you have m such zeros Z_1, Z_2, \dots, Z_m are the zeros, which are basically nothing, but the roots of the numerator polynomial. Remember we are assuming a rational function; that is Z transform is given by r_i is it given as a rational function of Z , and that is its of the form of a numerator polynomial divided by a denominator polynomial and P_1, P_2, \dots, P_n . These are; obviously, the poles, and we have these are the n poles.

And let us assume that n greater than or equal to m and further assume, all poles are simple; that is there are no repeated poles noise. This implies there are no repeated poles in which case I can express Xz over z , the partial fraction expansion of Xz over (Refer Time: 11:52) is given as C naught over z plus C_1 over z minus p_1 plus c_2 over z minus p_2 plus.

(Refer Slide Time: 11:54)

\Rightarrow No Repeated Poles.

$$\frac{X(z)}{z} = \frac{C_0}{z} + \frac{C_1}{z-p_1} + \frac{C_2}{z-p_2} + \dots + \frac{C_n}{z-p_n}$$

$$= \frac{C_0}{z} + \sum_{k=1}^n \frac{C_k}{z-p_k}$$

$$C_0 = X(z)|_{z=0}$$

$$C_k = (z-p_k)X(z)|_{z=p_k}$$

So, on C_n over z minus P_n which can be simplified as C_n over z plus the summation k equals 1 to n C_k over z minus P_k , where the coefficient C_n can be found as C_n equals simply evaluate $X(z)$ at z equal to 0, and C_k is basically given as z minus P_k times $X(z)$ evaluated at z equals P_k .

(Refer Slide Time: 13:24)

$z^{-1} + \sum_{k=1}^n \frac{z^{-1}}{z-p_k}$

$$C_0 = X(z)|_{z=0}$$

$$C_k = (z-p_k)X(z)|_{z=p_k}$$

$$X(z) = C_0 + \frac{C_1 z}{z-p_1} + \frac{C_2 z}{z-p_2} + \dots + \frac{C_n z}{z-p_n}$$

Compute Z Transforms of individual Terms. Sum together.

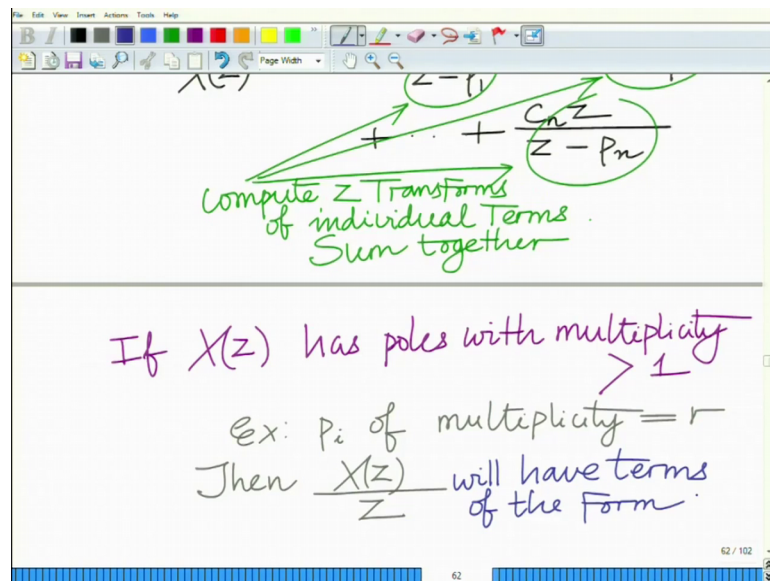

And finally, we have substituting the values of C_0 to C_n , where we have n simple poles we have, and taking the Z in the denominator on to the other side, we have

X equals $C_1 Z$ divided by $Z - P_1$ plus $C_2 Z$ divided by $Z - P_2$ plus $C_n Z$ divided by $Z - P_n$.

And now the inverse transform can be found, because remember we know the inverse transform of each factor, which is of the form $Z - P_i$ over $Z - P_i$. We know the inverse transform of every such term, and therefore, now forming the Z transforms of these individual partial fractions and then forming the sum that gives us the inverse Z transform of this, of this rational function of Z . So, we know the Z transform. So, for instance 0 minor or $Z - P_1$ Z over $Z - P_2$ Z or Z ; so, put these together. So, compute Z transforms of these terms, compute Z transforms of the individual terms, and then followed by their sum ok.

So, that gives us the inverse Z transform. Now if Xz has multiple poles.

(Refer Slide Time: 15:22)

If Xz , if fz has poles with multiplicity greater than 1; that is imply, lets say example P_i of pole P_i of multiplicity equals r correct multiple multiplicity means multiplicity greater than 1, means repeated poles that is your terms of the form $Z - P_i$ square multiplicity of 2 or multiplicity of 3 implies Z you have a term of the form $Z - P_i$ cube; that is pole P_i has multiplicity of 3. So, in that scenario.

If you, if let us say pole P_i has multiplicity r then Xz over Z will have terms of the form.

(Refer Slide Time: 16:56)

If $X(z)$ has poles with multiplicity > 1

Ex: p_i of multiplicity $= r$

Then $\frac{X(z)}{z}$ will have terms of the form

$$\frac{\lambda_1}{z-p_i} + \frac{\lambda_2}{(z-p_i)^2} + \dots + \frac{\lambda_r}{(z-p_i)^r}$$

$$\lambda_{r-k} = \frac{1}{k!} \left. \frac{d^k}{dz^k} \frac{(z-p_i)^k X(z)}{z} \right|_{z=p_i}$$

each such pole P_i with multiplicity greater than 1 will contribute to two terms of the form λ_1 by Z minus P_i over λ_2 by Z minus P_i square plus λ_r over Z minus P_i raised to the power of r , where this quantity λ_{r-k} , k equals. Well 0 to $r-1$, this will be given as 1 over k factorial d , d raised to k over $d z$ to the k minus P_i raised to the k Xz by z evaluated at; that is the k th derivative of Z minus P_i raised to the power of k times Xz over Z evaluated at Z equals P_i .

So, this is the expression for. So, this is the expression for λ_{r-k} . So, this is the expression hold the term λ_{r-k} , which basically there is a coefficient of the term Z minus P_i raised to the power of $r-k$ alright. So, we have λ_1 or Z minus P_i λ_2 or Z minus P_i square so on and so forth. λ_r over Z minus P_i raised to the power of r the coefficient λ_{r-k} is 1 over k factorial d to the k ; that is d raised to the power k over $dz^k z$ minus p_i to the power of k Xz over z evaluated at Z equal to P_i ; that is a k th derivative of Z minus P_i raised to k into Xz over Z evaluated at is equal to P_i . And from this, once again one can find the inverse Z transform of the given function.

Let us now look at the properties of the region of convergence.

(Refer Slide Time: 19:20)

$\sum_{r=k}^{\infty} c_k z^k \quad \leftarrow |z=p_k$

PROPERTIES OF ROC:

#1: ROC does NOT contain any pole.

#2: If $x(n) = \text{Finite Sequence}$
 $\Rightarrow x(n) = 0$ For $n < N_1$
or $n > N_2$.

The properties of the ROC, the properties of the ROC are as follows; number 1, ROC does not, the ROC does not contain any part 2, if x_n equals of finite implies that x_n equal to 0, for either x_n equals 0 for n less than n_1 or n greater than n_2 ; that is it is nonzero, only in the interval n_1 to n_2 and Xz converges for some value of Z Xz converges for some value of Z alright. Then this implies that ROC equals the entire Z plane.

(Refer Slide Time: 20:47)

PROPERTIES OF ROC:

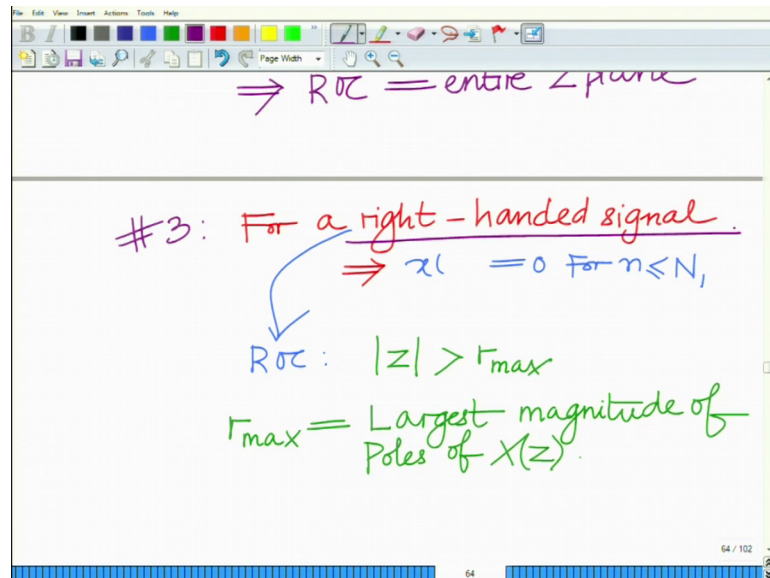

#1: ROC does NOT contain any pole.

#2: If $x(n) = \text{Finite Sequence}$
 $\Rightarrow x(n) = 0$ For $n < N_1$
or $n > N_2$
and $X(z)$ converges for some
value of Z
 $\Rightarrow \text{ROC} = \text{entire } z \text{ plane}$

So, the point is that basically if you have a finite sequence; that is if the sequence is not infinite, it is a finite sequence. It exists only in a finite region; that is it exists only in the

finite interval n_1 to n_2 ; that is 0. If n is less than n_1 or 0, if n is greater than n_2 and it is nonzero, only in this interval n_1 to n_2 , then basically the Z transform of that signal that is a finite signal exists everywhere on the Z plane, if it converges for a single point, if it converges for any single point it exists everywhere on the Z plane; that is the entire Z plane now for a right handed signal.

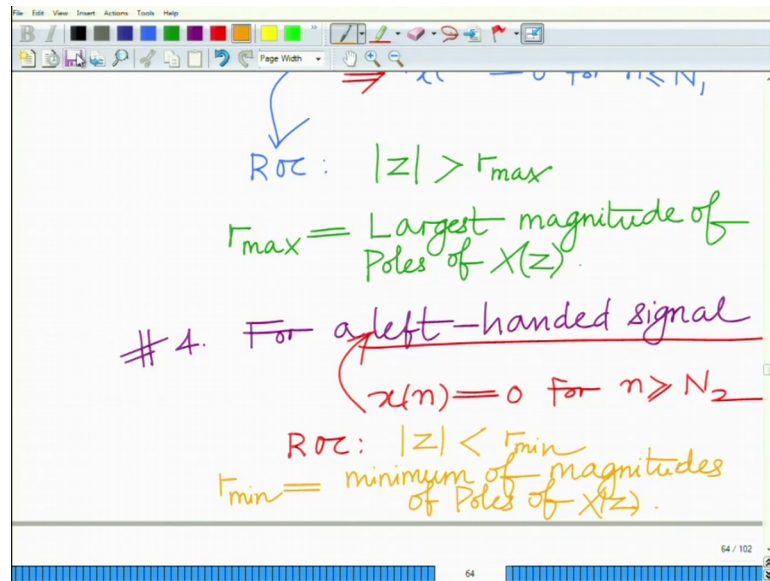

(Refer Slide Time: 22:00)

Again this is something similar to the Laplace transform for right handed signal. Now right handed signal implies that x_n equals 0; that is there exist some n_1 that says our x and equals 0 for n less than equal to n_1 . Now this implies for a right handed signal ROC is of the form magnitude of Z; that is ROC is of the form magnitude of Z greater than r_{\max} , where r_{\max} equals the magnitude largest magnitude of the largest or largest. This is the largest magnitude of the poles of poles of x of z .

So, r_{\max} is the largest amongst the magnitudes of the poles of Xz . And if it is a right handed signal, then the ROC has to be. If it is a right handed signal then the ROC has to be of the form magnitude of Z greater than r_{\max} . Now similarly for a left-handed signal.

(Refer Slide Time: 23:47)

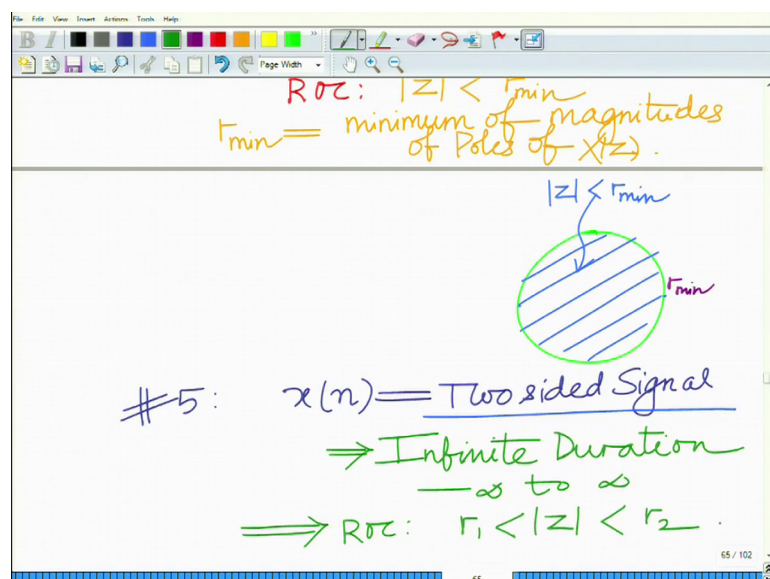

ROC: $|z| > r_{max}$
 $r_{max} =$ Largest magnitude of Poles of $X(z)$.

4. For a left-handed signal
 $x(n) = 0$ for $n \geq N_2$
ROC: $|z| < r_{min}$
 $r_{min} =$ minimum of magnitudes of Poles of $X(z)$.

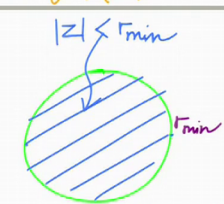

Now what is the left handed signal? once again left handed signal is, if x_n equals 0 for some n greater than or equal to n_2 ; that is there exist an n_2 such that x_n equals 0 for n greater than equal to n_2 . This implies that the ROC is of the form magnitude of Z is less than r_{min} , r_{min} equals smallest magnitudes; that is the minimum of the magnitude, minimum of the magnitude, minimum of the magnitudes of poles of X of c ; that is magnitude Z is less than that is for a left-handed signal. You have the ROC is of the form magnitude Z less than r_{min} , that r_{min} is the minimum of the magnitudes of the poles of X of c . So, your ROC will be of the form.

(Refer Slide Time: 25:35)

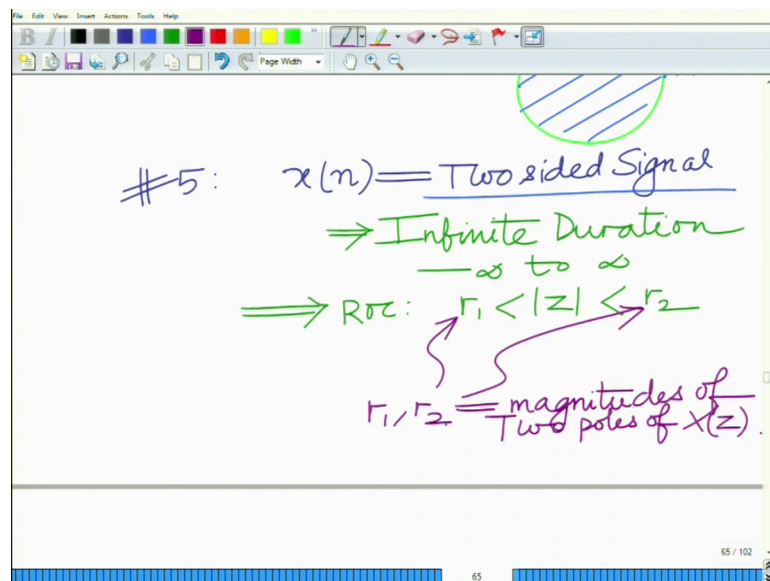

ROC: $|z| < r_{min}$
 $r_{min} =$ minimum of magnitudes of Poles of $X(z)$.

#5: $x(n) =$ Two sided Signal
 \Rightarrow Infinite Duration
 $-\infty$ to ∞
 \Rightarrow ROC: $r_1 < |z| < r_2$.

So, if this is r_{\min} minimum the magnitude of the poles, your ROC will inside, be inside this circle that is magnitude Z less than r_{\min} , where r_{\min} is. So, ROC will be interior of the circle or the circular region. So, this is the ROC, is of the form magnitude Z less than r_{\min} . And finally, if x_n is a 2 sided signal. Now if x_n equals a 2 sided signal; that is this infinite duration from minus infinity to infinity minus infinity to infinity. Then this implies that the ROC is of the form r_1 less than magnitude of Z is less than r_2 .

(Refer Slide Time: 27:12)

Now, r_1 and r_2 these are the magnitudes of two poles, the form r_1 less than magnitude z less than r_2 , where r_1, r_2 are the magnitudes of two poles of X of z . So, these are the properties of the ROC. Remember the ROC stands for region of convergence once again. I think we have seen that enough times before. So, I do need to go or that again. So, ROC stands for the region of convergence, and we have seen the properties of the ROC for several signals; that is what happens to the ROC for a finite signal of finite duration, ROC for a left-handed signal right handed signal and then a 2 sided signal all right. So, these are useful properties of the ROC. One has to bear in mind while, and this helps us better construct, reconstruct as well as analyze the properties of a signal by looking at this as Z transform this alright.

So, we will stop here and continue with other aspects in the subsequent modules.

Thank you very much.
