Conditions for Existence of Fourier Series – Dirichlet Conditions, Magnitude/ Phase Spectrum, Parseval's Theorem

Hello welcome to another module in this massive open online course. So, we are looking at the Fourier analysis and in particular the Fourier series of continuous time periodic function all right. So, in this module let us start by looking at the conditions for the existence of the Fourier series.

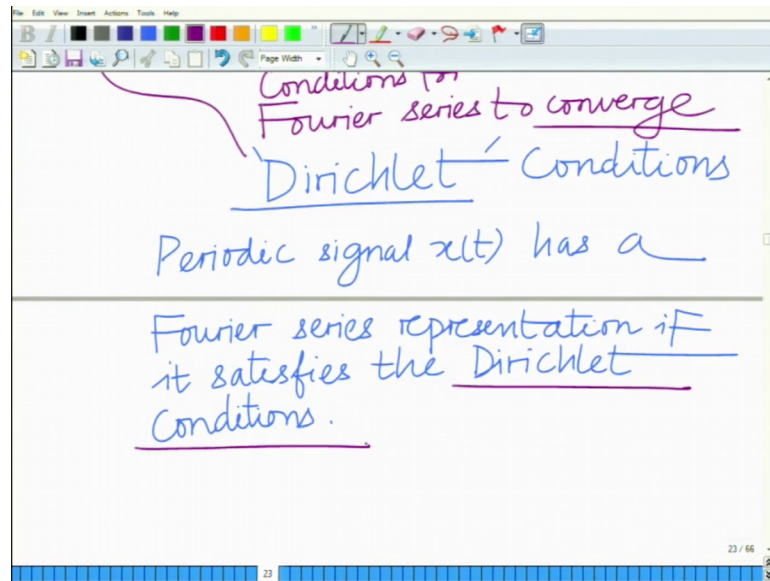

(Refer Slide Time: 00:31)

So, what we want to start with is the conditions for existence of Fourier series.

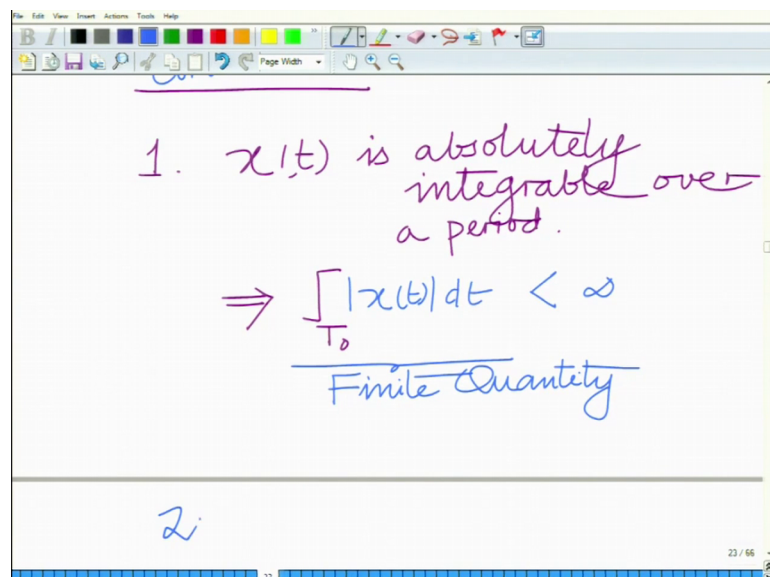

Under what conditions thus the Fourier series converge, no gas conditions for existence of the Fourier series. Basically known as a conditions for the convergence, for the Fourier series to converge that is conditions for the Fourier series to converge and these are also known as the these are also the Dirichlet, the Dirichlet conditions these are also known as the Dirichlet after the mathematician Dirichlet ok.

(Refer Slide Time: 01:38)

So, these are known as the Dirichlet conditions. So, next we have a Fourier series representation that is a periodic signal $x(t)$, has a Fourier series representation, if it satisfies the Dirichlet conditions. If it satisfies the Dirichlet conditions and these are as follows that is the Dirichlet conditions which are to be satisfied for the existence of the Fourier series are as follows that is $x(t)$ is absolutely integrable over a period.

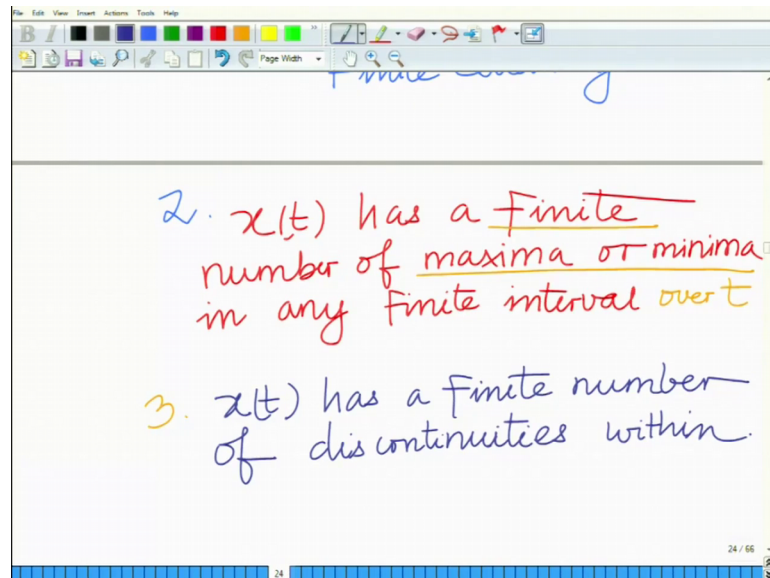

(Refer Slide Time: 02:53)

This implies that is if you look at this integral over a period of magnitude of $x(t) dt$ this has to converge or this has to be a finite quantity. So, over a period if you integrate

magnitude of $x(t)$ that is integral only period T of duration T naught continuous period of duration T naught where T naught is a fundamental period correct integral over any fundamental period T naught magnitude $x(t)$ has to be a finite quantity. So, this has to be a finite, this has to be a finite quantity and $x(t)$ has a finite number of maxima or minima.

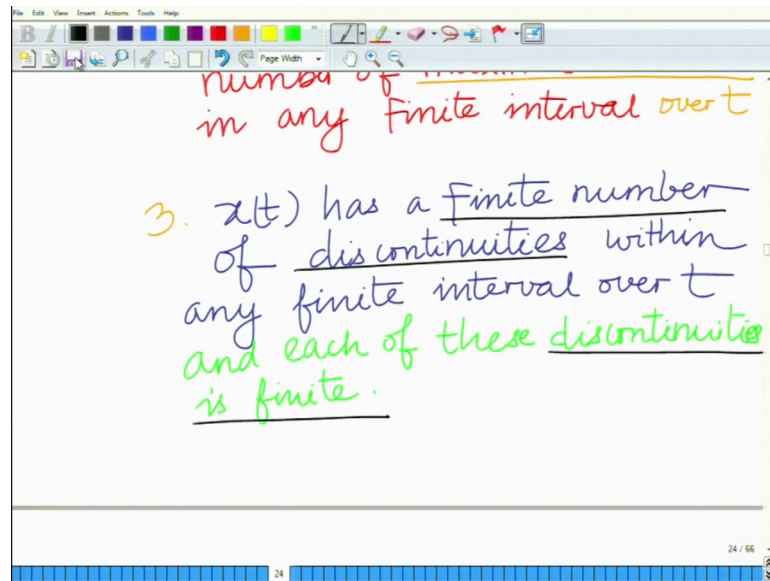

(Refer Slide Time: 04:08)

So, the other condition is $x(t)$ has a finite number of maxima or minima, finite number of maxima in any finite interval in any in any finite number of maxima or minima, in any finite interval over time. In any finite interval over t and the third condition that is the number of that is we look at any finite any interval of a finite duration the number of maxima and minima there is a number of extremum, number of extrema of this signal $x(t)$ has to be final ok.

And the third condition is that $x(t)$ has a finite number of discontinuities, the signal $x(t)$ has a finite the number of discontinuities, $x(t)$ is a finite number of discontinuities within any finite interval of duration t .

(Refer Slide Time: 05:56)

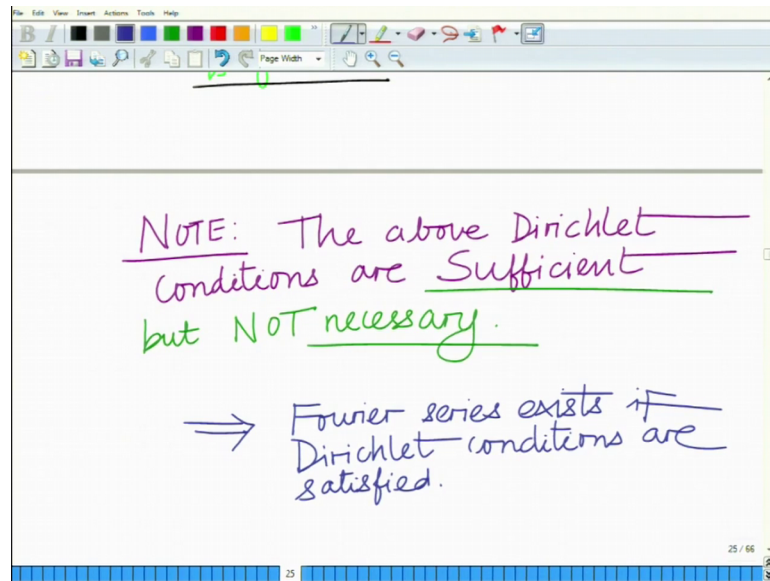

Any finite interval over t and each of these discontinuities is finite and moreover that it has a finite number of discontinuities, it has a finite number of discontinuities and each of these discontinuities is finite that is a third Dirichlet condition. So, these are the 3 Dirichlet conditions, Dirichlet conditions that is your first is that $x(t)$ is absolutely integrable.

That is integral over any fundamental period T of the magnitude of $x(t)$ has to be finite all right and $x(t)$ has a finite number of maxima or minima in any inter finite interval of finite duration over time and finally, $x(t)$ has a finite number of discontinuities and each of at each of these points the $x(t)$ the signal $x(t)$ is finite in any interval of finite duration over time ok.

Now, an important thing to note is that, these are sufficient conditions right; these are not necessary.

(Refer Slide Time: 07:26)

Note the above Dirichlet conditions, conditions are sufficient these are sufficient, but not necessary implies that the Fourier series exists.

If the Dirichlet conditions are satisfied, but not the other way round that is it is not that the Dirichlet conditions are satisfied if the Fourier series exists. So, these are sufficient conditions all right, which means that if these conditions are satisfied by this by the signal $x(t)$ then the by a periodic signal $x(t)$ by a continuous periodic signal $x(t)$ then the Fourier series exists all right.

So, these are summary these are the conditions for the Fourier series to exist for a continuous periodic signal $x(t)$ all right. Let us also look at the next topic which is the amplitude and phase spectrum.

(Refer Slide Time: 09:20)

AMPLITUDE AND PHASE

SPECTRUM: $x(t)$

continuous periodic signal.

Complex Fourier series coefficients of $x(t)$ can be expressed as,

$$c_k = |c_k| e^{j\phi_k}$$

26 / 66

So, what we want to look at now is the amplitude and phase spectrum of this continuous periodic signal, amplitude and phase spectrum of $x(t)$ we remember we are still looking at we are still looking at a continuous periodic signal, they are looking at a continuous periodic signal.

Now, the complex Fourier series coefficients of $x(t)$ remember these are complex, the complex of $x(t)$ can be expressed as magnitude this can be expressed as c_k equals, magnitude c_k $e^{j\phi_k}$ that is this is the magnitude of c_k and this is the phase of c_k , this is the phase.

(Refer Slide Time: 11:02)

$$C_k = |C_k| e^{j\phi_k}$$

Phase of C_k
magnitude of C_k
$$\phi_k = \angle C_k$$

Plot of $|C_k|$ versus angular Frequency ω — Termed as amplitude spectrum.
$$\phi_k = \angle C_k \text{ versus } \omega$$

In fact, you can also write ϕ_k equals the angle of this coefficient C_k .

Now, plot, if you plot this magnitude C_k versus the frequencies the discrete frequencies that is $k\omega_0$ remember the coefficients C_k are defined for the fundamental frequency ω_0 and multiples of the fundamental frequency that is at harmonics corresponding to ω_0 . So, if you plot this magnitudes of the Fourier coefficients C_k versus $k\omega_0$ all right versus ω this is termed as the magnitude spectrum of the signal $x(t)$. So, plot of, plot of magnitude C_k versus angular frequency ω correct angular frequency ω this is termed as the amplitude spectrum.

This is termed as a amplitude spectrum and similarly my plot of ϕ_k that is which is the angle of C_k versus ω this is term as your phase spectrum the plot of ϕ_k versus ω that is the phase, versus ω this is termed as the phase spectrum

(Refer Slide Time: 12:59)

The image shows a whiteboard with handwritten notes. At the top, it says $\phi_k = \angle C_k$ versus ω and labels this as the Phase Spectrum. Below that, a note states that $|C_k|$ and ϕ_k are not continuous functions of ω . An arrow points to these terms with the text 'Exist only at Discrete Frequencies $k\omega_0$ '. A further note specifies that k is an integer and ω_0 is the Fundamental Angular Frequency. The whiteboard interface includes a toolbar at the top and a page number '27' at the bottom.

Now, observe that these only exist that is this magnitude c_k ϕ_k only exists at discrete set of points that is at k times, ω_0 where ω_0 is the fundamental angular frequency therefore, this is also known as a discrete frequency spectrum or also known as a line spectrum ok.

So, note so note that c_k . So, note that magnitude c_k comma ϕ_k these are not continuous functions of ω of the angular frequency ω , these exist only at discrete set of frequencies, $k\omega_0$ where k is an integer and ω_0 equals fundamental angular frequency ok.

These only exist at a discrete set of frequencies and therefore, hence termed as the discrete frequency spectra or line spectra.

(Refer Slide Time: 14:53)

Fundamental Angular Frequency

Hence, Termed as discrete Frequency Spectrum or Line spectrum.

For a real periodic signal $x(t)$ we have,

$$C_{-k} = C_k^*$$

Hence termed as a discrete frequency spectrum or what is also known as a line spectrum, discrete frequency spectrum or a line spectrum. Now, further if you look at a real periodic signal, when the signal is real remember we have said that the Fourier coefficients right the Fourier coefficients that is C of minus k is the conjugate of the Fourier coefficient C of k corresponding to k of corresponding to the frequency $k\omega$ naught. So, for a real signal in fact, for a real periodic signal for a real periodic signal, $x(t)$ we have the coefficient C of minus k equals C_k conjugate.

Now, what this means is this implies.

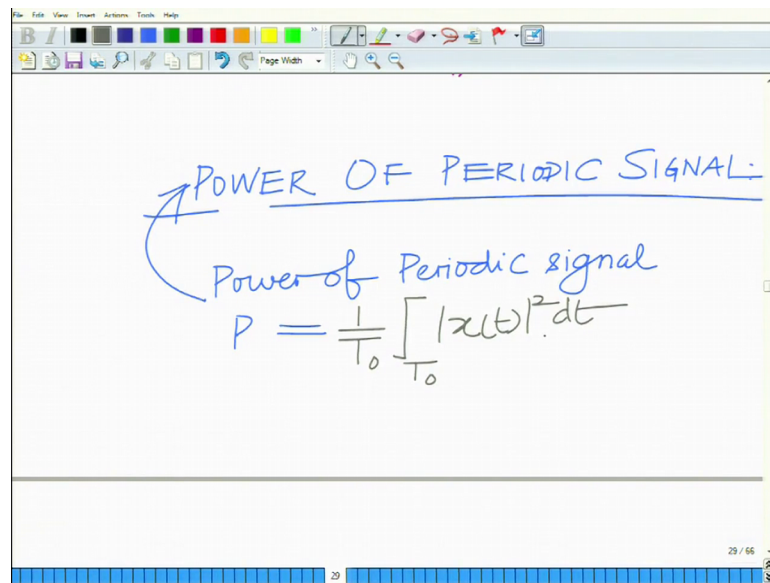

(Refer Slide Time: 16:21)

The image shows a whiteboard with handwritten notes in green and purple ink. At the top, it states $C_{-k} = C_k^*$. Below this, two green arrows point to $|C_{-k}| = |C_k|$ and "Magnitude spectrum = Even Function of ω ". A horizontal line separates this from the bottom section, where two purple arrows point to $\phi_{-k} = -\phi_k$ and "Phase Spectrum = odd Function". The whiteboard interface includes a toolbar at the top and a status bar at the bottom right showing "29 / 66".

Firstly this implies that magnitude C of minus k equals magnitude because they are complex conjugate of each other magnitude of C of minus k equals magnitude equals magnitude C of minus C of k , implies the magnitude spectrum is an even function of frequency magnitude spectrum is an even function of ω . Further we have since they are complex conjugate of each other this also implies what this also implies is that the phase or angle of C of minus k phase of minus k is minus of phase of k .

This implies that the phase spectrum is an odd function. So, we have magnitude spectrum which is even function the phase spectrum which is an odd function this is for a real periodic signal $x(t)$ all right. Let us now look at the power of this periodic signal and the property of the power.

(Refer Slide Time: 17:44)

POWER OF PERIODIC SIGNAL:

Power of Periodic signal

$$P = \frac{1}{T_0} \int_{T_0} |x(t)|^2 dt$$

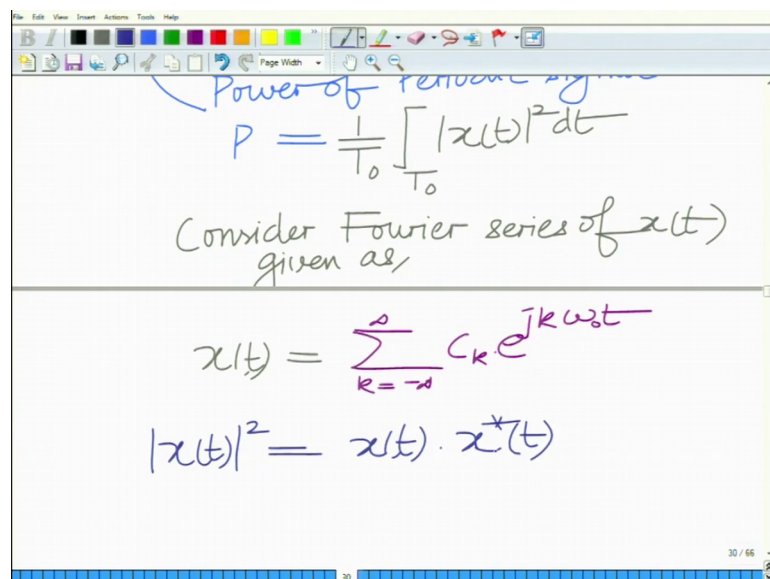

29 / 66

So, let us now look at another aspect that is the power of the.

Let us now look at this other aspect, which is the power of the periodic signal and we have power of the periodic signal, this is equal to this is given as P equals one over T naught, this is defined as integral 1 over T naught or any fundamental period t naught magnitude x t square d t this is the power of the periodic signal x t.

Now, what we are going to do is we are going to prove a property using the Fourier series. So, consider the Fourier series the Fourier series of x t.

(Refer Slide Time: 18:48)

Power of periodic signal

$$P = \frac{1}{T_0} \int_{T_0} |x(t)|^2 dt$$

Consider Fourier series of $x(t)$ given as,

$$x(t) = \sum_{k=-\infty}^{\infty} c_k e^{jk\omega t}$$
$$|x(t)|^2 = x(t) \cdot x^*(t)$$

30 / 66

Now, consider the Fourier series of $x(t)$ given as, $x(t)$ equals summation k equal to minus infinity to infinity $C_k e^{jk\omega_0 t}$. Let us say this is the Fourier series, then magnitude of $x(t)$ square is remember magnitude of a quantity, magnitude of quantity square is simply $x(t)$ times $x(t)$ conjugate which is equal to, now first I am going to write $x(t)$.

(Refer Slide Time: 19:47)

The image shows a whiteboard with handwritten mathematical equations. The first equation is
$$= \left(\sum_{k=-\infty}^{\infty} C_k e^{jk\omega_0 t} \right) \times \left(\sum_{m=-\infty}^{\infty} C_m e^{jm\omega_0 t} \right)^*$$
 The second equation is
$$= \sum_{k=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} C_k C_m^* e^{j(k-m)\omega_0 t}$$
 The whiteboard also shows a toolbar at the top and a status bar at the bottom with the number 30.

Yes which is we already have the expression in terms of the Fourier series that is summation over k , $C_k e^{jk\omega_0 t}$ multiplied by $x(t)$ conjugate. I am just going to change the index that is summation m equal to I can change the index summation m equal to minus infinity to infinity $C_m e^{jm\omega_0 t}$ whole conjugate and.

Now, if I open the brackets and expand this what I am going to have is I am going to have summation k equal to minus infinity to infinity, summation m equal to minus infinity to infinity, $C_k C_m^* e^{j(k-m)\omega_0 t}$. So, this is what I have. So, what I am doing is basically I am representing $x(t)$ in terms of its Fourier series considering $x(t)$ into $x(t)$ conjugate of t and that gives me magnitude $x(t)$ square ok.

(Refer Slide Time: 21:15)

$k = -\infty \quad m = \infty$

Therefore, For power, we have,

$$\frac{1}{T_0} \int_{-T_0}^{T_0} |x(t)|^2 dt = \frac{1}{T_0} \int_{-T_0}^{T_0} \sum_{k=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} \frac{C_k C_m^*}{x e^{j(k-m)\omega_0 t}} dt$$

And now, therefore, for the power therefore, for the power we have 1 over t naught magnitude x t squared dt, this is 1 over t naught substitute the expression above for magnitude x t square. This is 1 over T naught that is integral, remember this integral is over any duration t naught any period or any time interval contiguous time interval of duration t naught summation m equals minus infinity to infinity, ck cm conjugate times e raised to j k minus m omega naught t dt and.

(Refer Slide Time: 22:26)

$$\frac{1}{T_0} \int_{-T_0}^{T_0} |x(t)|^2 dt = \frac{1}{T_0} \int_{-T_0}^{T_0} \sum_{k=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} \frac{C_k C_m^*}{x e^{j(k-m)\omega_0 t}} dt$$

interchange sum/integral.

$$= \sum_{k=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} C_k C_m^* \frac{1}{x} \int_{-T_0}^{T_0} e^{j(k-m)\omega_0 t} dt$$

$$= \begin{cases} 1 & \text{if } k = m \\ 0 & \text{otherwise} \end{cases} = \delta(k-m).$$

Now, if I interchange the sum slash integral we bring the summations outside. So, that will give me k equals minus infinity to infinity, summation m equal to minus infinity to infinity $c_k c_m^*$ $\int_{-T_0/2}^{T_0/2} e^{j(k-m)\omega_0 t} dt$.

And we have seen this integral, that is integral of any harmonic of omega naught right any complex exponential with its frequency that is an integer multiple of omega naught you integrate it over the period t naught it is 0, unless all right unless k is equal to m in which case this is e raised to 0 which is 1 the integral over duration of t naught is t naught divided by t naught which is 1. So, this is equal to 1.

If k equals m and 0 otherwise implies this is basically the discrete impulse that is delta k minus m equals 1 if k equals m k equals to m and 0 otherwise.

(Refer Slide Time: 23:51)

The image shows a whiteboard with the following handwritten mathematical derivation:

$$= \sum_{k=-\infty}^{\infty} \sum_{m=-\infty}^{\infty} c_k c_m^* \delta(k-m)$$

$$= \sum_{k=-\infty}^{\infty} |c_k|^2$$

$$P = \frac{1}{T_0} \int_{-T_0/2}^{T_0/2} |x(t)|^2 dt = \sum_{k=-\infty}^{\infty} |c_k|^2$$

Parseval's Identity
or Parseval's Theorem

So, this is summation k equals minus infinity to infinity, summation m equals minus infinity to infinity $c_k c_m^*$ $\delta(k-m)$ which is of course, now exists only that is now only the terms corresponding to k equal to m survive all the rest of the terms are 0.

So, this is summation k equal to minus infinity, $c_k c_k^*$ which is magnitude c_k square and therefore, we have showed a very important property a very important and very interesting property which is basically that if I compute the power in the time

domain of this periodic signal that is magnitude $x(t)$ squared that is equal to summation k equal to minus infinity to infinity magnitude C_k squared and this is known as the Parseval's identity or the Parseval's theorem.

So, this important property is known as the Parseval's identity or this is also known as Parseval's also known as Parseval's theorem all right. So, that is an interesting property. So, what we have seen in this module is we have looked at the conditions for that that is the Dirichlet conditions. Dirichlet conditions for the existence of which are the sufficient conditions for the existence of the Fourier series representation or the convergence of the Fourier series representation of a periodic signal, continuous time periodic signal $x(t)$ and we have also seen the Parseval's relation which relates the power of continuous time periodic signal $x(t)$ to its Fourier series representation all right. So, we will stop here and look at other aspects in the subsequent modules.

Thank you very much.
