Fourier Transform of Exponential, Unit Step Function, Properties of Fourier Transform – Linearity, Time Shifting, Frequency Shifting, Time-Reversal

Hello, welcome to another module in this massive open online course. So, we are looking at the Fourier transform and the properties of the Fourier transform of continuous signals all right. So, let us continue our discussion.

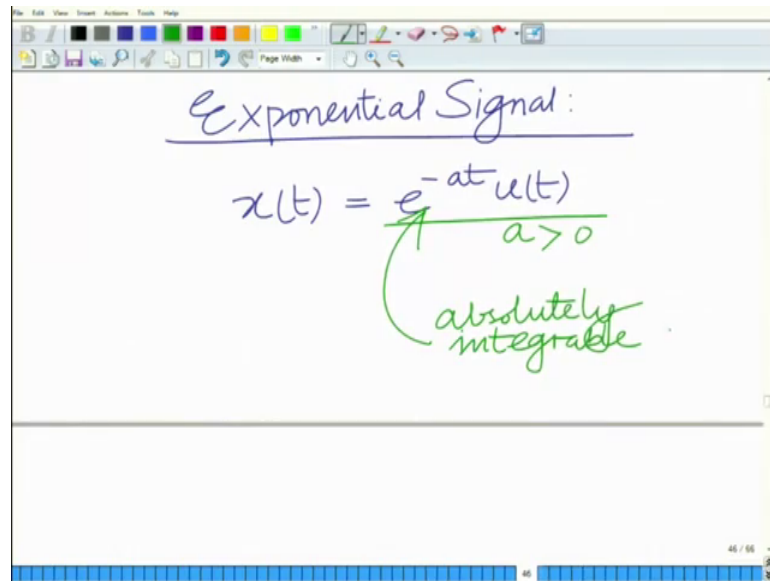

(Refer Slide Time: 00:27)

So, we are looking at the Fourier transform and the properties of the Fourier transform. We have looked at the Fourier transform of the impulse signal ok.

Let us now look at the Fourier transform of the exponential of an exponential signal; that is a signal of the form $x(t)$ equals e raised to minus t $u(t)$ assuming that a is a positive quantity a is greater than 0. Now, notice that this signal is absolutely integrable ok.

(Refer Slide Time: 01:26)

The image shows a handwritten slide titled "Exponential Signal:". Below the title, the signal is defined as $x(t) = e^{-at}u(t)$. A green arrow points from the text "absolutely integrable" to the expression $e^{-at}u(t)$. The condition $a > 0$ is written below the expression. The slide is presented in a software window with a toolbar at the top and a status bar at the bottom showing "46 / 66".

Exponential Signal:

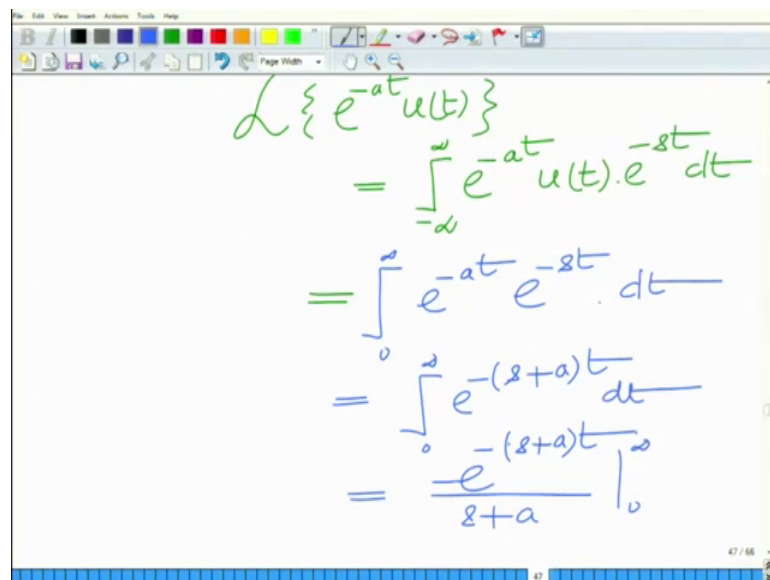

$$x(t) = e^{-at}u(t)$$

$a > 0$

absolutely integrable

Notice that this is an absolutely if you look at this signal this signal is an absolutely integrable signal this is an absolutely integrable signal and in fact, if you look at the Laplace transform of this.

(Refer Slide Time: 01:56)

The image shows a handwritten slide deriving the Laplace transform of the exponential signal. The derivation starts with the Laplace transform definition: $\mathcal{L}\{e^{-at}u(t)\} = \int_{-\infty}^{\infty} e^{-at}u(t)e^{-st}dt$. This is simplified to $\int_0^{\infty} e^{-at}e^{-st}dt$, then to $\int_0^{\infty} e^{-(s+a)t}dt$. The final result is $\frac{e^{-(s+a)t}}{-(s+a)} \Big|_0^{\infty} = \frac{1}{s+a}$. The slide is presented in a software window with a toolbar at the top and a status bar at the bottom showing "47 / 66".

$$\mathcal{L}\{e^{-at}u(t)\}$$
$$= \int_{-\infty}^{\infty} e^{-at}u(t)e^{-st}dt$$
$$= \int_0^{\infty} e^{-at}e^{-st}dt$$
$$= \int_0^{\infty} e^{-(s+a)t}dt$$
$$= \frac{e^{-(s+a)t}}{-(s+a)} \Big|_0^{\infty}$$
$$= \frac{1}{s+a}$$

You can check the Laplace transform of this the Laplace transform of this is Laplace transform of $e^{-at}u(t)$ this is integral minus infinity to infinity or integral. In fact, let me just write it integral minus infinity to infinity $e^{-at}u(t)e^{-st}dt$

Now, it is nonzero only for t greater than or equal to 0. So, this reduces to the integral 0 to infinity e^{-st} and for t greater than or equal to 0 this is 1. So, so e^{-st} raised to minus st in that is integral 0 to infinity e^{-st} plus a dt which is $1/(s+a)$ times e^{-st} plus a . In fact, minus $1/(s+a)$ e^{-st} plus a evaluated between the limit 0 to infinity.

(Refer Slide Time: 03:08)

The image shows a whiteboard with the following handwritten content:

$$= \frac{1}{s+a}$$

$\text{If } \text{Re}\{s+a\} > 0$
 $\Rightarrow \text{Re}\{s\} > -a$
 ROC: includes $\text{Re}\{s\} = 0$
 $s = \sigma + j\omega$
 $\sigma = 0$

And this is equal to if s plus a is greater than equal to 0, this is equal to $1/(s+a)$; if s plus a greater than 0 implies that is remember real part of s plus a greater than 0; this implies that the roc therefore, from the Laplace transform you will remember that real part of s is greater than minus a

Now, since a is positive since a is positive this includes real part of s equal to 0 includes ok. So, what we are observing is that; if you look at the roc of the Laplace transform that is real part of s is greater than minus a , but since we have said a is greater than 0; that is a positive quantity therefore, real part of s greater than some negative quantity which implies that real part of s is equal to 0 is in the ROC.

And, now if you look at this the complex frequency s equals $\sigma + j\omega$ real part of s equal to 0 implies σ equal to 0. So, implies $j\omega$ is in the roc.

(Refer Slide Time: 04:26)

The image shows a whiteboard with handwritten notes. At the top, it says $s = j\omega$ belongs to ROC if $a > 0$. Below that, it says "Fourier Transform". The main part of the whiteboard shows the derivation of the Fourier Transform of $e^{-at}u(t)$. It starts with the integral $\int_0^{\infty} e^{-at} e^{j\omega t} dt$, which is then evaluated to $\frac{-e^{-(a+j\omega)t}}{a+j\omega} \Big|_0^{\infty}$.

$$s = j\omega \text{ belongs to ROC if } a > 0$$

Fourier Transform

$$= \int_0^{\infty} e^{-at} e^{j\omega t} dt$$
$$= \frac{-e^{-(a+j\omega)t}}{a+j\omega} \Big|_0^{\infty}$$

So, $s = j\omega$ belongs to the ROC if a is greater than 0 and this is nothing, but $s = j\omega$ this is nothing, but $a = j\omega$ we are nothing, but the Fourier transform and. In fact, if you evaluate the Fourier transform you will observe that the Fourier transform equals integral minus infinity to infinity e^{-at} or directly write integral 0 to infinity $e^{-at} e^{j\omega t} dt$, which is $e^{-at} e^{j\omega t}$ divided by $a + j\omega$ evaluated between the limits 0 to infinity.

(Refer Slide Time: 05:39)

The image shows a whiteboard with handwritten notes. It shows the Laplace transform $X(s) = \frac{1}{a+s}$ and the Fourier transform $X(j\omega) = \frac{1}{a+j\omega}$. A green arrow points from the Laplace transform to the Fourier transform. Below this, it says $\lim_{t \rightarrow \infty} e^{-(a+j\omega)t} = 0$ since $a > 0$. At the bottom, it says "Fourier Transform obtained by setting $s = j\omega$ " and "Laplace Transform".

$$X(s) = \frac{1}{a+s}$$
$$X(j\omega) = \frac{1}{a+j\omega}$$

$\lim_{t \rightarrow \infty} e^{-(a+j\omega)t} = 0$ since $a > 0$.

Fourier Transform obtained by setting $s = j\omega$

Laplace Transform

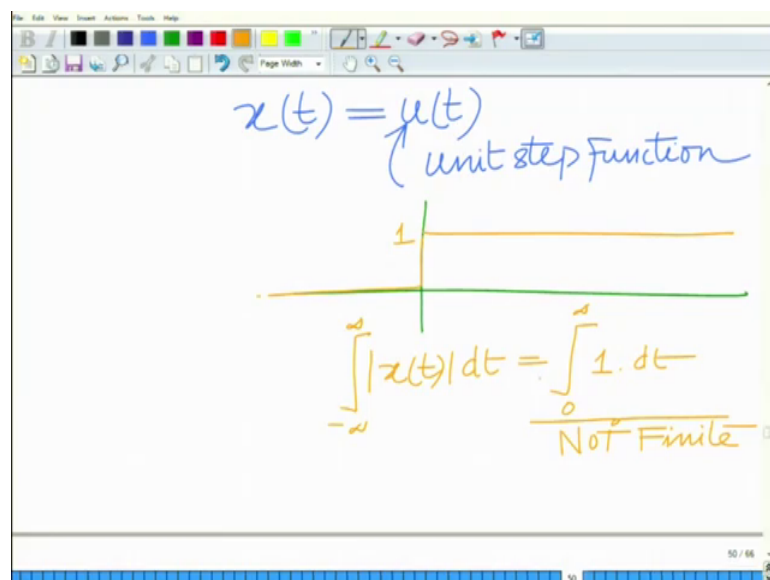

And this would be $1/(1 + j\omega)$ and this is your $X(\omega)$ is $1/(1 + j\omega)$.

And, here we are assuming that we are setting $e^{-j\omega t}$ limit t tending to infinity equals 0 since $\sigma > 0$ that is for $\sigma > 0$. Remember this is a decreasing exponential it is absolutely integrable therefore, its Fourier transform exists. In fact, the Fourier transform is obtained by setting s equal to $j\omega$ in the Laplace transform remember the Laplace transform is $1/(s + a)$ set s equal to $j\omega$ you obtain $1/(j\omega + a)$ which is. In fact, the Fourier transform exists.

So, the Fourier transform. So, it is absolutely integrable and observe that the Fourier transform is observed is obtained by setting s equal to $j\omega$ in the Laplace transform is obtained by setting s equal to $j\omega$ in the Laplace transform and also note that this follows since $x(t)$ the signal $x(t)$ is absolutely integrable.

Now, let us see a scenario where that is not to let us consider a signal which is not absolutely integrable.

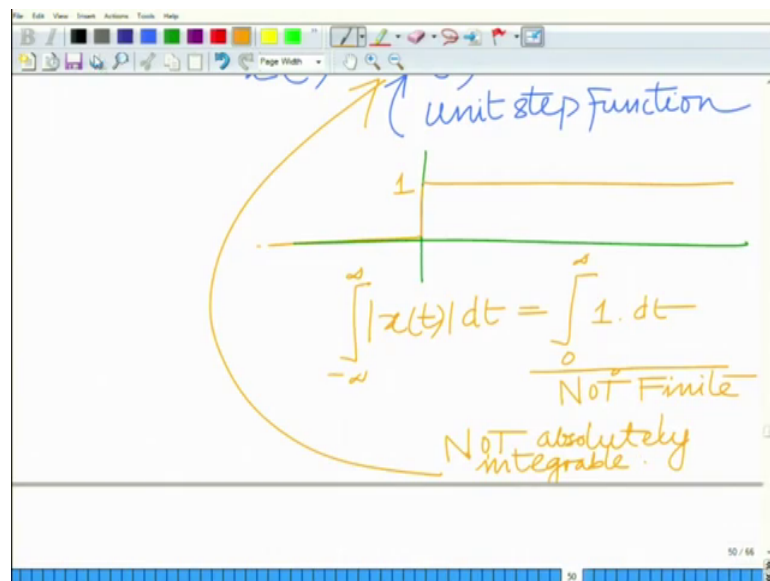

(Refer Slide Time: 07:30)

For instance consider $x(t)$ equals the unit step function $x(t)$ equals the unit step function and that looks like this if you look at 0 for t less than equal to 0 for t greater than equal to 0 0 for t less than 0 this is 1 for t greater than or equal to 0.

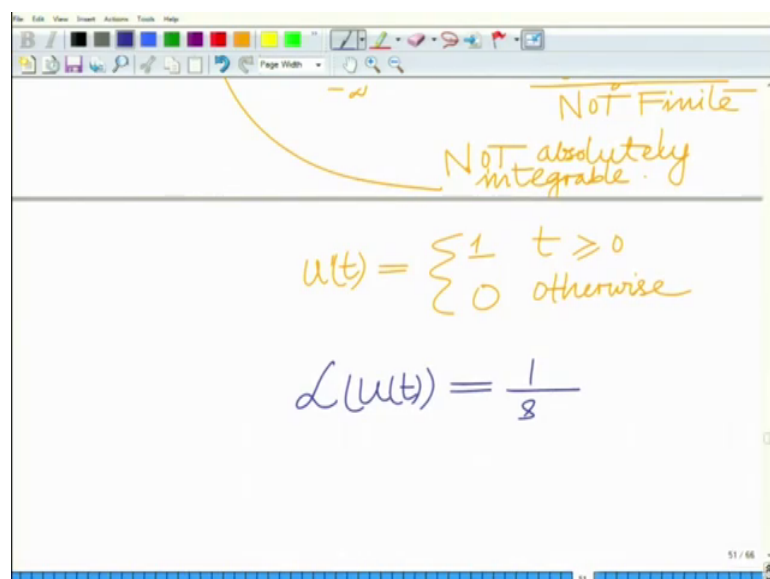

And, now if you look at integral minus infinity to infinity magnitude $x(t) dt$ that is integral 0 to infinity times 1 dt and this is not finite you can clearly see this is not finite.

(Refer Slide Time: 08:35)

And therefore, this signal is not absolutely integrable not absolutely this is not absolutely integrable.

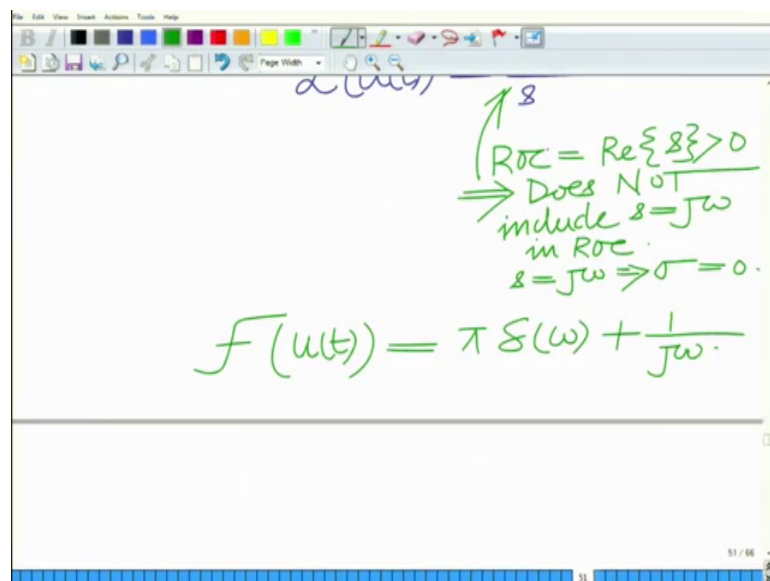

(Refer Slide Time: 08:54)

And. In fact, if you look at the Laplace transform. So, u t remember ut let me just write down the expression for ut ut equals 1 for t greater than equal to 0 this is 0 otherwise and. In fact, you will remember that the Laplace transform of u t equals 1 over s ok. So, the Laplace transform of u t is 1 over s and the region of convergence roc of the Laplace transform remember the roc of the Laplace transform is a real part of s greater than 0, which means the sigma that is a real part of this complex frequency has to be greater than 0 all right.

So, it does not equal sigma. So, it does not equal include sigma equal to sigma equals 0, in the region of convergence therefore, the J omega axis is not present in the region of convergence of this signal ok, which means that you cannot employ the straight Fourier transform in a straightforward fashion ok, region of convergence ROC.

(Refer Slide Time: 10:01)

A real part of s greater than 0 implies does not include s equal to J omega in roc s equal to J omega implies sigma equals 0; that is a real part of s that is equal to 0.

And in fact, if you look at the Fourier transform you cannot evaluate this in a straightforward fashion, but the Fourier transform of this exists and the Fourier transform it can be shown to be given as pi of delta omega plus 1 over J omega. In fact, if you have if you set s equal to J omega in the Laplace transform all you will obtain is 1 over J omega. So, you will miss this factor which is pi times delta omega.

In fact, this is therefore, you can see that the Fourier transform is not obtained by setting s equal to $j\omega$ in the Laplace transform; because well s equal to 0 does not that is real part of s equal to 0 is not in the region of convergence and you can also see that this function is not absolutely integrable. So, naughty this is not obtained from Laplace transform not obtained from the Laplace transform by setting.

(Refer Slide Time: 11:54)

The image shows a handwritten slide with the following content:

include $s = j\omega$
in ROC.
 $s = j\omega \Rightarrow \sigma = 0$.

$$F(u(t)) = \pi \delta(\omega) + \frac{1}{j\omega}$$

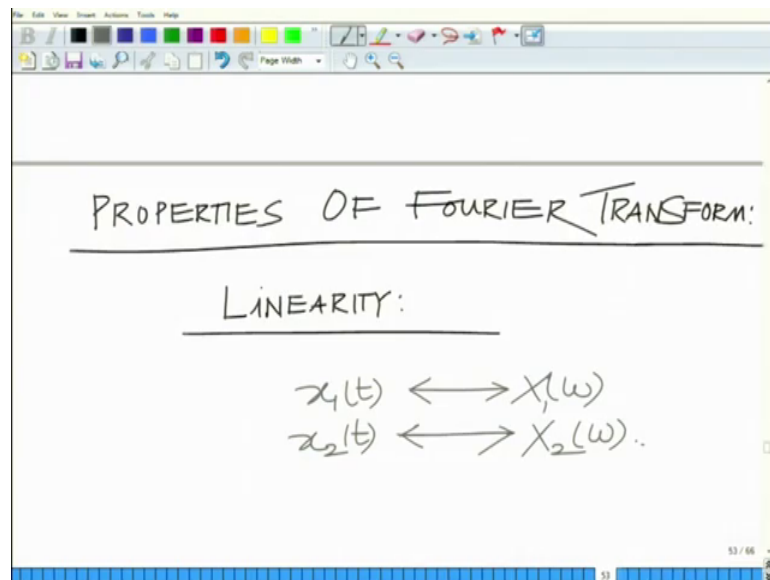

NOT obtained From
Laplace Transform by
setting $s = j\omega$.

52 / 66

s equal to $j\omega$ there is a Laplace transform is not obtained by replacing s equal to $j\omega$ in the. So, the Fourier transform is not obtained from by replacing s equal to $j\omega$ in the Laplace transform; because it is not absolutely integrable ok.

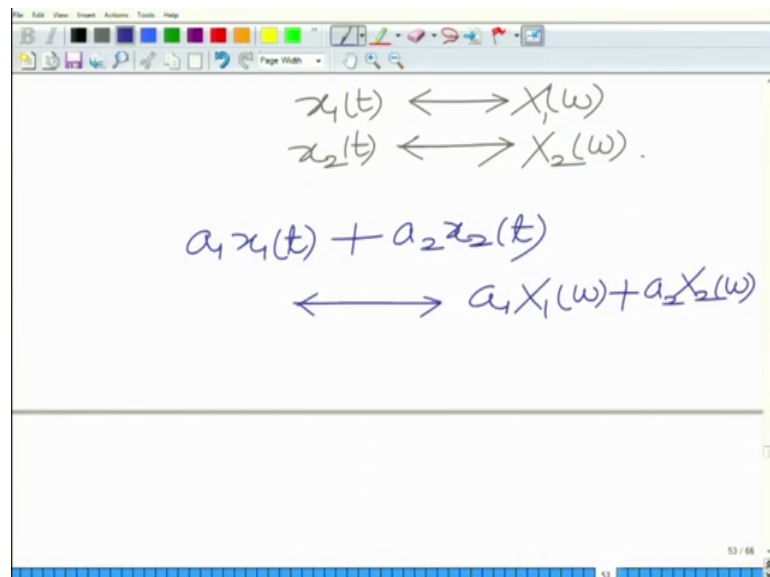

Let us, now continue our discussion let us look at the properties of the Fourier transform or let me just start this on a different page we want to look at the properties of the Fourier transform.

(Refer Slide Time: 12:31)

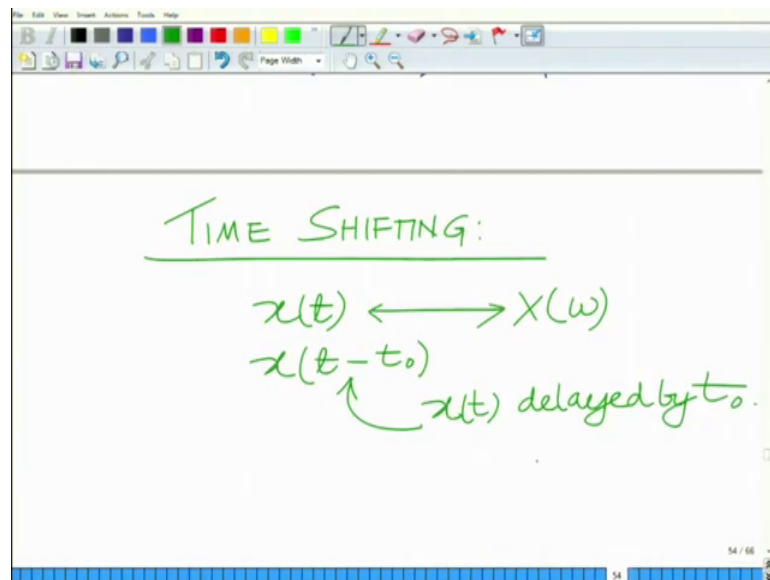

And the first property that we want to look at is what is termed as the linearity property of the Fourier transform; it is very simple if you have 2 signals $x_1(t)$ with Fourier transform $X_1(\omega)$ and $x_2(t)$ which has the Fourier transform $X_2(\omega)$.

(Refer Slide Time: 13:25)

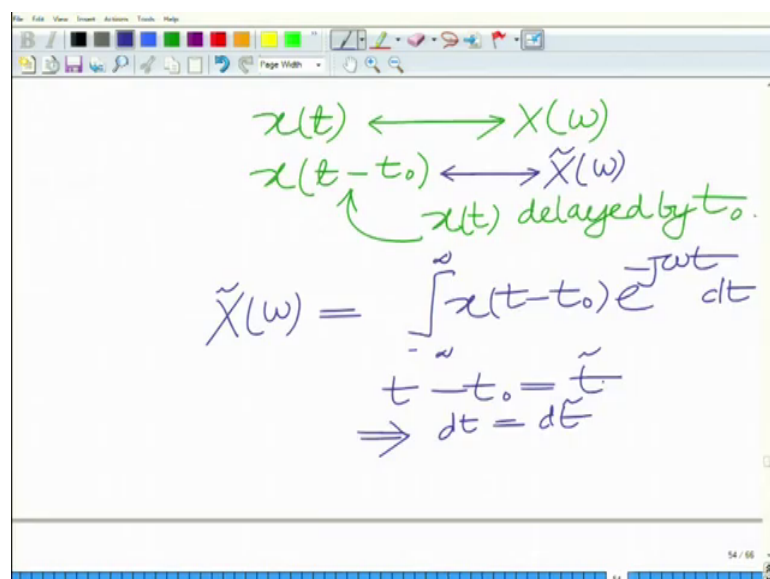

Then $x_1(t)$ plus $x_2(t)$ or $a_1 x_1(t)$ plus $a_2 x_2(t)$ has the Fourier transform $a_1 X_1(\omega)$ plus $a_2 X_2(\omega)$ ok; this is the Fourier transform.

(Refer Slide Time: 13:53)

The time shifting property let us look at another property which is the time shifting property which is $x(t)$ has the Fourier transform X of ω consider a time shift x of t minus t_0 that is this is x of $t - t_0$ that is the signal x of t minus t_0 . So, we are considering x of t which is the Fourier transform X of ω capital X of ω what is the Fourier transform of x of t minus t_0 and this can be obtained as follows; now let us call this Fourier transform as \tilde{x} of ω

(Refer Slide Time: 14:53)

Now $\tilde{X}(\omega)$ is minus infinity to infinity $x(t - t_0) e^{-j\omega t}$ dt. Now set $t - t_0 = \tilde{t}$ that implies $dt = d\tilde{t}$ and therefore, now if you simplify this.

(Refer Slide Time: 15:27)

$$\begin{aligned}
 &= \int_{-\infty}^{\infty} x(\tilde{t}) e^{-j\omega(\tilde{t} + t_0)} d\tilde{t} \\
 &= \int_{-\infty}^{\infty} x(\tilde{t}) e^{-j\omega\tilde{t}} d\tilde{t} \cdot e^{-j\omega t_0} \\
 &= X(\omega) \cdot e^{-j\omega t_0} \\
 \tilde{X}(\omega) &= X(\omega) e^{-j\omega t_0}
 \end{aligned}$$

Complex Exponential.

I can write this as minus infinity to infinity $x(t - t_0) e^{-j\omega t}$ dt is $x(\tilde{t}) e^{-j\omega(\tilde{t} + t_0)} d\tilde{t}$. So, this is basically $\tilde{t} = t - t_0$. So, this is basically $\tilde{t} = t - t_0$ plus t_0 dt is $d\tilde{t}$ which is basically now minus infinity to infinity $x(\tilde{t}) e^{-j\omega\tilde{t}} d\tilde{t} e^{-j\omega t_0}$ and if you look at this this is nothing, but $X(\omega)$. So, we have finally, that $\tilde{X}(\omega) = X(\omega) e^{-j\omega t_0}$ and this is basically you can see that this is equal to a complex exponential there are complex exponential ok

(Refer Slide Time: 16:44)

$$\tilde{X}(\omega) = X(\omega) e^{-j\omega t_0}$$

$$x(t - t_0) \leftrightarrow X(\omega) e^{-j\omega t_0}$$

Complex Exponential

Shift in Time \leftrightarrow Modulation in Frequency

So, basically what we are seeing is that $x(t - t_0)$ has the Fourier transform $X(\omega) e^{-j\omega t_0}$. So, this is the Fourier transform; that is basically shift in time which implies multiplication by or modulation. This complex exponential is nothing, but modulation. So, this is modulation in shift in time basically results in a modulation in the frequency all right. So, if a shift in time $x(t - t_0)$ the signal it is delayed by denote the corresponding Fourier transform is multiplied by this factor $e^{-j\omega t_0}$ which is $e^{-j\omega t_0}$ in the frequency ok.

(Refer Slide Time: 17:57)

Time in Frequency

FREQUENCY SHIFTING:

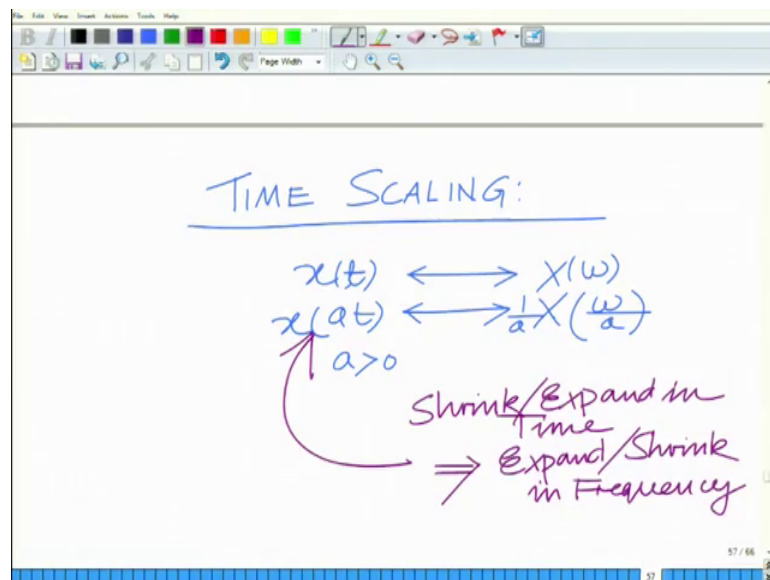

$$e^{j\omega_0 t} x(t) \leftrightarrow X(\omega - \omega_0)$$

Modulation in Time Shift in Frequency Domain

Now, let us look at another property which is the frequency shifting property of the Fourier transform. So, let us look at the frequency shifting property you know the frequency shifting property this states that again it is a dual of the time shift that is if you have the modulation if you have a modulation in time $e^{j\omega_0 t}$ $x(t)$ in frequency you have $X(\omega - \omega_0)$.

So, this basically shows and you can easily demonstrate this similar to what we have done above. So, this is basically modulation in time that is multiplying by this complex exponential $e^{j\omega_0 t}$ this is equal to shift in frequency domain. This is basically a shift in the frequency this results in a shift in the frequency domain and then another interesting property is basically the time scaling property.

(Refer Slide Time: 19:17)

And this is as follows consider $a > 0$, that is a positive constant then now let us consider $x(t)$ ok. Let us start with that $x(t)$ as the Fourier transform $X(\omega)$ then $x(at)$ where a is a positive scaling factor that is assume that $a > 0$ as the Fourier transform $\frac{1}{a} X(\frac{\omega}{a})$.

Now this is interesting because now look at this if $a > 0$ all right you can see that $x(at)$ is a shrunk version of $x(t)$ that is x is a is for instance let us say $5x(t)$ times t is basically $x(t)$ the shrinks by a factor of 5 by a factor of 5.

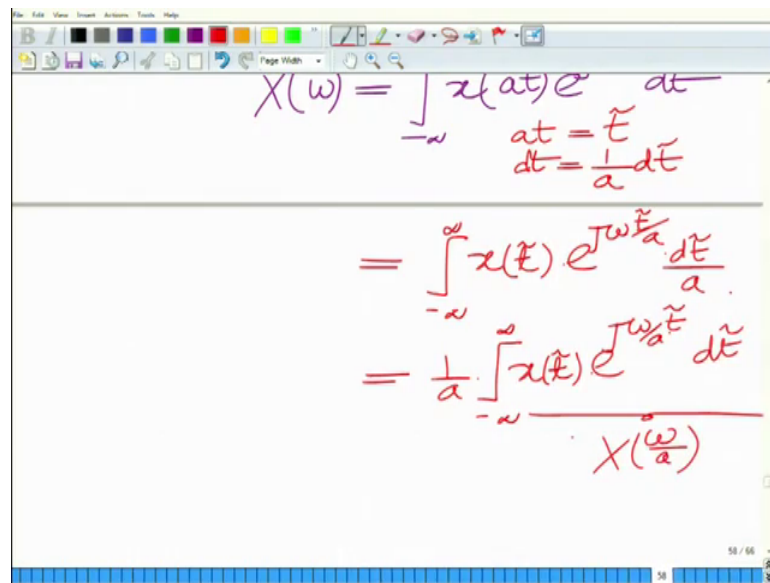

So, in the frequency domain, what happens is you have x of ω over 5 which means it expands by a factor of 5. Similarly if a is less than 1 then x of a is an expanded version of a and correspondingly X of ω over a is a shrunk version of X of ω . So, basically expansion in the time leads to a shrinking in the frequency and similarly a shrinking in a time all right scaling down in time leads to an expansion or scaling up in frequency ok.

So, basically what we have is it is a very interesting property. So, shrink slash expand in time leads to the opposite effect expand slash shrink in frequency. So, what happens is if it is well localized in time that is it becomes more and more localized in time it becomes less and less localized in frequency all right and you can clearly see the example of this that is when in time it becomes extremely narrow. It becomes an impulse in time, then frequency it is spread over the entire frequency axis which is basically it is one the you can see that the Fourier transform for impulse in time is one that is spreads over entire frequency axis minus infinity to infinity.

As it starts shrinking in time as it starts as it starts expanding in time then starts shrinking in frequency all right and this know this is a well known property of the Fourier transform the time domain representation and it is Fourier transform that is time frequency localization all right. So, it is well localized in time then it is not well localized in frequency it is well localized in frequency or it is poorly localized a time that is it is wider in time then it shrinks in the in the then it is as it starts to become wider in the time domain it starts to shrink in the frequency domain ok.

So, this is an important property and you can see this as follows the proof of this is straightforward for a equal to greater than 0.

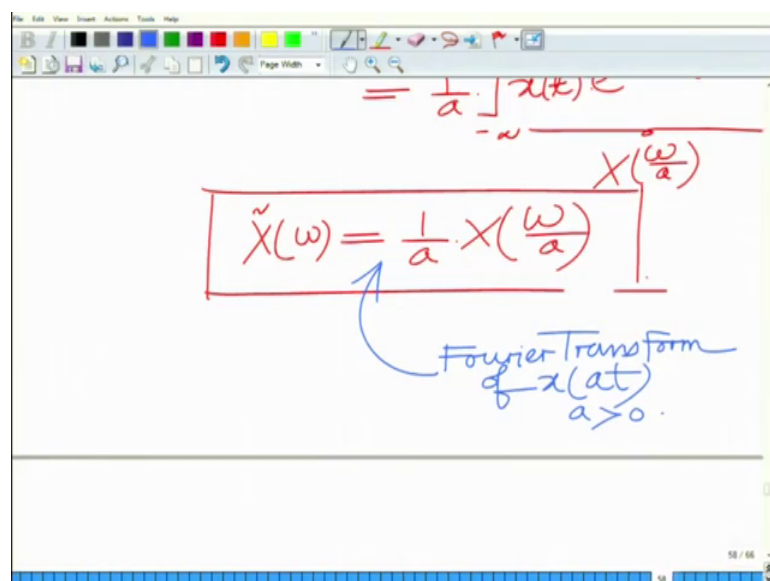

(Refer Slide Time: 22:33)

$$\begin{aligned}
 X(\omega) &= \int_{-\infty}^{\infty} x(at) e^{j\omega t} dt \\
 &= \int_{-\infty}^{\infty} x(\tau) e^{j\omega \frac{\tau}{a}} \frac{d\tau}{a} \\
 &= \frac{1}{a} \int_{-\infty}^{\infty} x(\tau) e^{j\omega \frac{\tau}{a}} d\tau \\
 &= \frac{1}{a} X\left(\frac{\omega}{a}\right)
 \end{aligned}$$

You have $\tilde{X}(\omega)$ the Fourier transform of $x(at)$ is minus infinity to infinity x of t $e^{j\omega t} dt$ set $at = \tau$ which means $dt = \frac{1}{a} d\tau$ which is minus infinity to infinity this is x of τ $e^{j\omega \frac{\tau}{a}}$ $\frac{d\tau}{a}$ which is nothing, but $\frac{1}{a}$ minus infinity to infinity x of τ $e^{j\omega \frac{\tau}{a}}$ $d\tau$ this is nothing, but this is X of $\frac{\omega}{a}$ over a remember we are assuming $a > 0$ therefore, we have.

(Refer Slide Time: 23:49)

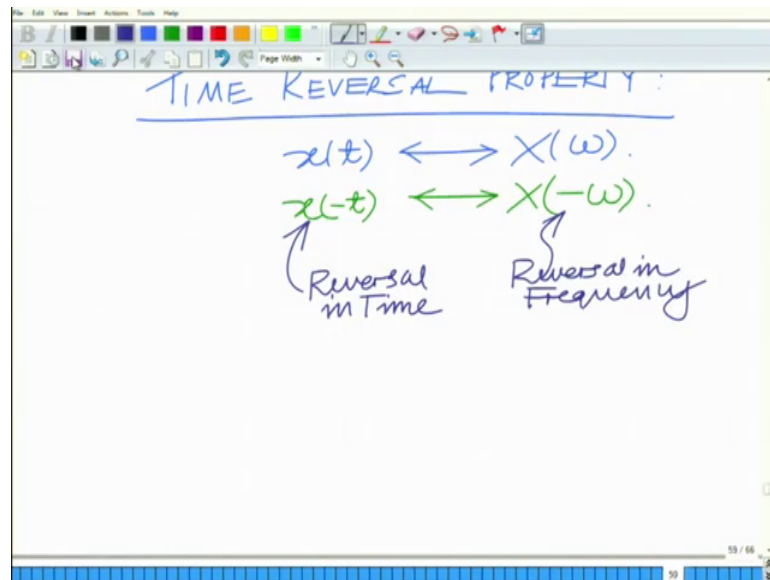

$$\tilde{X}(\omega) = \frac{1}{a} X\left(\frac{\omega}{a}\right)$$

Fourier Transform of $x(at)$ $a > 0$.

$\tilde{X}(\omega)$ equals $\frac{1}{a} X\left(\frac{\omega}{a}\right)$.

So, this is the Fourier transform of x of a t where a is greater than 0 a is greater than 0 and similarly you can show, what is known as the time reversal property the time reversal property or the time reversal property the time reversal property of the Fourier transform states.

(Refer Slide Time: 24:33)

That if $x(t)$ has the Fourier transform $X(\omega)$ then you can show that $x(-t)$ has the Fourier transform $X(-\omega)$ that is reversal in time leads to a reversal in frequency reversal in time leads to a reversal in frequency also this can also be shown very simply ah. So, we have reversal in time leads to a reversal in frequency this is the time reversal property of the Fourier transform all right.

So, what we have seen in this module is we have looked at some interesting properties. So, you consider continued our analysis of the Fourier transform we have looked at the Fourier transform the exponential and the unit step function and we also started looking at the at some of the interesting properties of the Fourier transform all right. So, we will stop here and continue in their subsequent modules.

Thank you very much.
