Practical Application: Multiple Input Multiple Output (MIMO) Beamformer Design

Hello welcome to another module in this massive open online course, so we are looking at MIMO beam forming; how to design the optimal transmit and receive Beamformers in a multiple input multiple output wireless communication system. So let us continue our discussion.

(Refer Slide Time: 00:29)

MIMO BEAMFORMING:

$$\bar{u}^H \bar{y} = \bar{u}^H H \bar{v} x + \bar{u}^H \bar{n}$$

Rx Beamformer TX Beamformer

So, what we want to look at is we want to look at MIMO beamforming and we have said after combining with \bar{u} Hermitian \bar{u} is at receive beamformer we have \bar{u} Hermitian H \bar{v} times x plus \bar{u} Hermitian noise this is the noise vector. Now, what we have to do is this is your receive beamformer and \bar{u} and \bar{v} is a transmit beamformer and we want to design this to maximize jointly design transmit and receive beamformers to maximization are first what we will do is we will set $H \bar{v}$.

(Refer Slide Time: 01:35)

$$H \bar{v} = \bar{h}$$
$$= \bar{u}^H \bar{h} x + \bar{u}^H \bar{n}$$

effectively becomes multiple RX antenna system

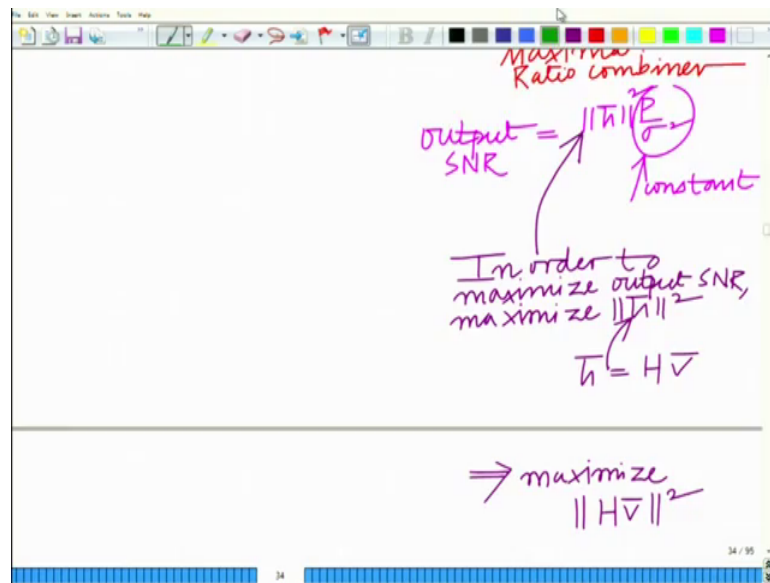

$$\bar{u} = \frac{\bar{h}}{\|\bar{h}\|}$$

Maximal Ratio Combiner

We will set this quantity equal to \bar{h} and now you will observe something interesting this becomes $\bar{u}^H \bar{h} x + \bar{u}^H \bar{n}$. Now if you see this \bar{h} this effectively becomes a single input multiple output system by setting \bar{v} equal to \bar{h} this effectively becomes us a SIMO system or a multiple simply multiple receiver antenna system.

For which we already know the optimal beamformer effectively becomes your multiple RX antenna system and once it become an RX antenna system what you have is that this is equal to. Now, therefore, now you know what is optimal beam former \bar{u} , the optimal beam former \bar{u} for this multiple antenna system optimal RX beamformer is the maximal ratio combiner; that is \bar{u} equals \bar{h} divided by norm \bar{h} ok. And therefore, we know this is the maximal ratio combiner, this is your optimal beamformer maximum this is a maximal ratio combiner.

(Refer Slide Time: 03:25)

And the output SNR of the maximal ratio combiner is given as $\|\mathbf{h}\|^2 P$ over σ^2 remember P is the transmit power σ^2 is the noise power. So, this quantity is constant P over σ^2 because, P is the transmit power σ^2 is the noise power implies that we have to maximize $\|\mathbf{h}\|^2$. So, to maximize the SNR we have to maximize $\|\mathbf{h}\|^2$ ok. So, in order to maximize SNR, so that is optimisation problem maximize or let us say maximize output SNR we have to maximize $\|\mathbf{h}\|^2$.

But \mathbf{h} equals we have seen $\mathbf{h} = \mathbf{H}\mathbf{v}$ or capital \mathbf{H} times \mathbf{v} . So, \mathbf{h} equals $\mathbf{H}\mathbf{v}$ which basically implies substituting this we have to maximize $\|\mathbf{H}\mathbf{v}\|^2$ which is basically $\|\mathbf{H}\mathbf{v}\|^2$. And what is $\|\mathbf{H}\mathbf{v}\|^2$ $\mathbf{H}\mathbf{v}$ square is the vector Hermitian itself for a complex vector which is basically $\mathbf{v}^H \mathbf{H} \mathbf{H} \mathbf{v}$ which is equal to $\mathbf{v}^H \mathbf{G} \mathbf{v}$.

(Refer Slide Time: 04:49)

$$\begin{aligned} &= \mathbf{v}^H \mathbf{H}^H \mathbf{H} \mathbf{v} \\ &= \mathbf{v}^H \mathbf{G} \mathbf{v} \\ &\quad \text{maximize.} \\ &\quad \mathbf{G} = \mathbf{H}^H \mathbf{H} \end{aligned}$$
$$\begin{aligned} \text{max. } & \mathbf{v}^H \mathbf{G} \mathbf{v} \\ \text{s.t. } & \|\mathbf{v}\| \leq 1 \end{aligned}$$

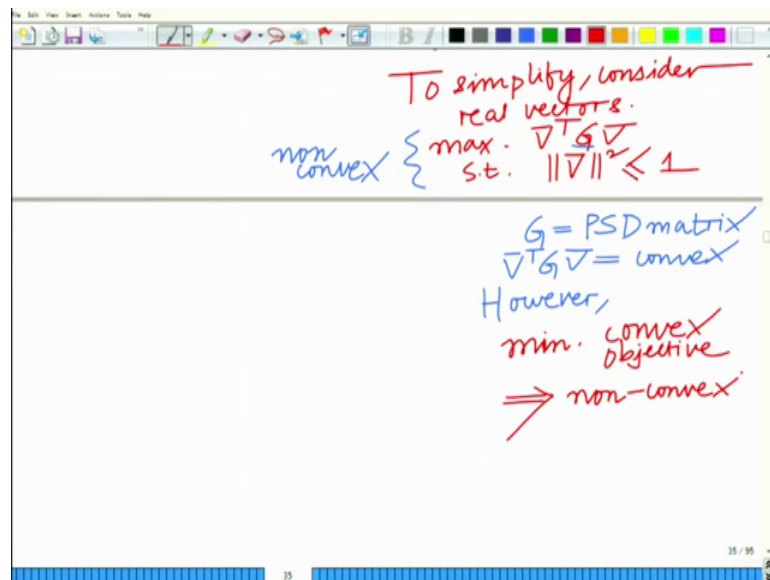

To simplify, consider real vectors.

$$\begin{aligned} \text{max. } & \mathbf{v}^T \mathbf{G} \mathbf{v} \\ \text{s.t. } & \|\mathbf{v}\|^2 \leq 1 \end{aligned}$$

So, we have to maximize this quantity where what is G , G equals H Hermitian H G equals H Hermitian H and we have to maximize. So, optimisation problem, so the net optimisation problem becomes maximize \mathbf{v}^H Hermitian G \mathbf{v} subject to the constraint remember the constraint is still there unit norm constraint that is the transmit beam former energy of the transmit beamformer or power of the transmit beam former $\|\mathbf{v}\|$ is less than or equal to 1. So, this is the resulting problem for optimal beam forming alright we have substituted $\mathbf{H}^H \mathbf{H}$ equals \mathbf{H} times \mathbf{v} bar and from that you derive this in terms of the optimal this optimisation problem for the optimal beam former.

And a now to just to simplify it what I am going today is I am going to assume real vectors I am going to place this Hermitian by transpose. So, I am going to say to simplify consider real vectors. So, this becomes \mathbf{v}^T G \mathbf{v} subject to the constraint $\|\mathbf{v}\| \leq 1$ or $\|\mathbf{v}\|^2 \leq 1$ both these constraints are equal equivalent and observe that interestingly this is a non-convex problem.

(Refer Slide Time: 07:01)

This is one of the few and very interesting non-convex ones because if you look at this $\bar{v}^T G \bar{v}$ is a convex function correct. However, we are maximizing it we are not minimizing remember standard form convex optimisation problem we have a convex objective, but your minimizing it here a convex objective your maximizing. So, the problem is a non-convex problem although the objective is convex because your maximizing it is it so non-convex.

In fact, if you minimize it you have to take the minimum and minimiser, but once you take the minimum the convex objective becomes a concave objectives as and therefore, it is a non-convex problem ok. And therefore, is because G is a positive semi definite matrix G equals a PSD matrix and $\bar{v}^T G \bar{v}$ equals convex however, what your doing is your minimizing a convex objective. Your performing minimization over a convex objective function implies that this is non-convex and therefore, now what will do is we will form the Lagrangian the same thing that we have done before.

(Refer Slide Time: 08:39)

$$\begin{aligned} & \Rightarrow \text{non-convex} \\ f(\bar{v}, \lambda) &= \bar{v}^T G \bar{v} + \lambda(1 - \|\bar{v}\|^2) \\ &= \bar{v}^T G \bar{v} + \lambda(1 - \bar{v}^T \bar{v}) \\ \nabla_{\bar{v}} f &= 2G\bar{v} + 0 - \lambda \cdot 2\bar{v} = 0 \end{aligned}$$

That is F of \bar{v} comma λ remember you have the objective $\bar{v}^T G \bar{v}$ plus λ times $1 - \|\bar{v}\|^2$ objective plus eigen plus Lagrange multiplier times constraint. This is equal to $\bar{v}^T G \bar{v}$ plus λ times $1 - \bar{v}^T \bar{v}$ now, differentiate it take its gradient with respect to \bar{v} this $\bar{v}^T G \bar{v}$ twice $G \bar{v}$ plus gradient of λ with respect to \bar{v} is 0 minus λ derivative of $\bar{v}^T \bar{v}$ is twice \bar{v} minus twice \bar{v} or it write minus twice $\lambda \bar{v}$ this is equal to 0 .

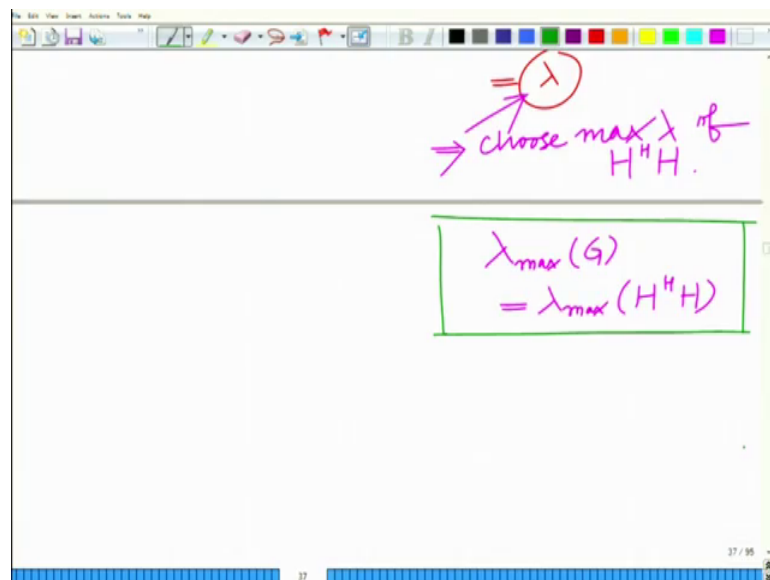

(Refer Slide Time: 09:41)

$$\begin{aligned} & \Rightarrow \boxed{G\bar{v} = \lambda \bar{v}} \\ & \bar{v} = \text{eigenvalue of } G = H^T H \\ & \text{How to find } \lambda? \\ & \bar{v}^T G \bar{v} \\ &= \bar{v}^T \lambda \bar{v} \\ &= \lambda \cdot \|\bar{v}\|^2 \end{aligned}$$

Now, if you solve this the two is cancel and therefore this implies that $G \bar{v}$ equals λ times \bar{v} and then you observe something very interesting what you observe is the $G \bar{v}$ equals $\lambda \bar{v}$. And recall you have already seen this kind of equation this equation before this is the nothing, but with the definition of the eigenvector of G that is any vector \bar{v} which satisfy this property that is G times \bar{v} vector equal simply a scaling factor λ times \bar{v} \bar{v} is the eigenvector and λ is the eigenvalue. So, that is the interesting property so what this shows is that the optimal transmit vector \bar{v} equals eigenvalue of G equals now you can write H Hermitian H that was just for simplicity.

So, there is a eigenvector of H Hermitian H there is an eigenvector of H Hermitian H right, but correct right. So, this has many eigenvalues now which eigenvalue now how to find which eigenvalue or you can say how to find the Lagrange multiplier λ ah. So, we can say that this will be $\bar{v}^T G \bar{v}$ now $G \bar{v}$ equals $\lambda \bar{v}$ so this because $\bar{v}^T \lambda$ into \bar{v} which is $\lambda \bar{v}^T \bar{v}$ which is λ times norm \bar{v} square, but norm \bar{v} square equal to 1 so this becomes λ .

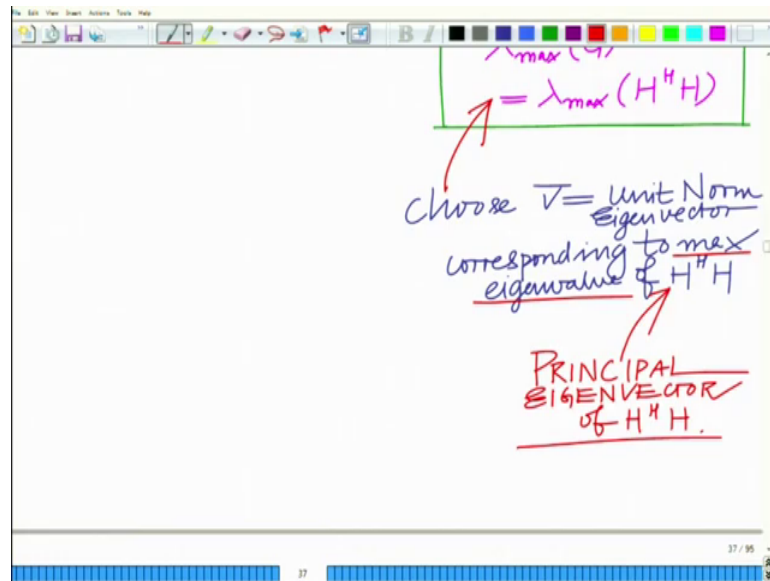

(Refer Slide Time: 11:15)

So, this is λ and you want to maximize this want to maximize $\bar{v}^T G \bar{v}$ implies choose the maximum λ or choose eigenvector corresponding to maximum λ eigenvalue of H Hermitian H . That is let us say we can denote this by

lambda max of G which is lambda max of H Hermitian H G is a H Hermitian H. And that is something that is extremely interesting what you have what it says is the transmit beamformer H Hermitian H corresponds to the max eigenvalue corresponding to the maximum eigenvector of H Hermitian H that is the transmit beamformer v bar unit norm transmit beamformer v bar which maximizes the SNR at the receiver.

(Refer Slide Time: 12:18)

So, choose v bar unit norm choose v bar equals unit norm eigenvector corresponding to maximum eigenvalue of corresponding to the maximum eigenvalue of H Hermitian H that is the interesting aspect. This is also termed this Eigen vector corresponding to the largest eigenvalue this also termed as the principal eigenvector, transmit beam former v Hermitian transmit beamformer v bar is the principal eigenvector corresponding to H Hermitian H.

(Refer Slide Time: 13:46)

The whiteboard contains the following handwritten text:

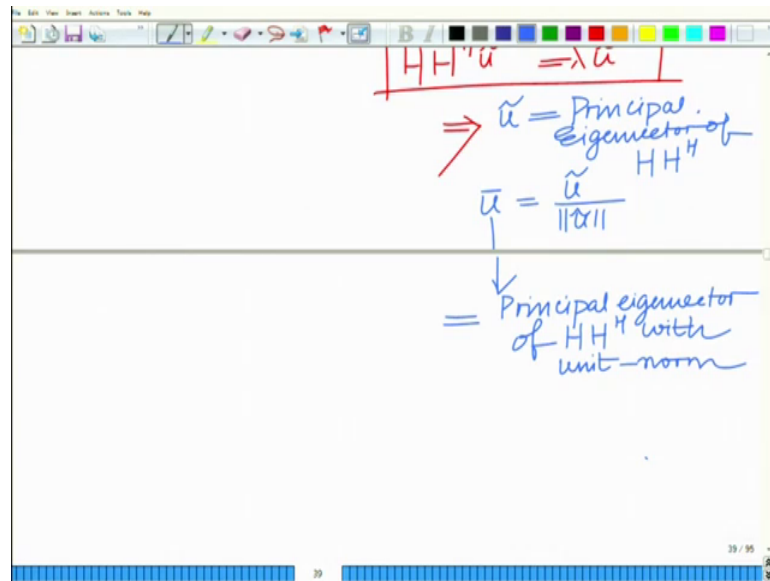

$$u = \frac{H\bar{v}}{\|H\bar{v}\|} \leftarrow \text{ignore}$$
$$\tilde{u} = H\bar{v}$$
$$HH^H \tilde{u} = H(H^H \cdot H\bar{v})$$
$$= H(\lambda \bar{v})$$
$$= \lambda H\bar{v}$$
$$\boxed{HH^H \tilde{u} = \lambda \tilde{u}}$$

$\Rightarrow \tilde{u} = \text{Principal Eigenvector of } HH^H$

Now whatever \bar{u} the receive beam former remember \bar{u} receive Beamformer we still have to find that that is $H\bar{v}$ divided by norm $H\bar{v}$. Now, this norm is simply normalization so for the time being ignore this \tilde{u} equals $H\bar{v}$ now look at this now perform $HH^H \tilde{u}$ equals HH^H Hermitian into $H\bar{v}$, but \bar{v} is eigenvector of H Hermitian H correct.

So, this will become H now look at this $HH^H H\bar{v}$ is equal to $\lambda \bar{v}$ so this is λ times $H\bar{v}$, but $H\bar{v}$ is \tilde{u} . So, what we have here is we have shown something very interesting $HH^H \tilde{u}$ equals $\lambda \tilde{u}$ implies \tilde{u} is the Eigen that is the receive beam former \tilde{u} is the eigenvector of the matrix HH^H Hermitian and that is something that is interesting \tilde{u} . Again you can see \tilde{u} or now you can say \tilde{u} equals principal eigenvector of HH^H Hermitian that is eigenvector corresponding to largest eigenvalue of HH^H Hermitian.

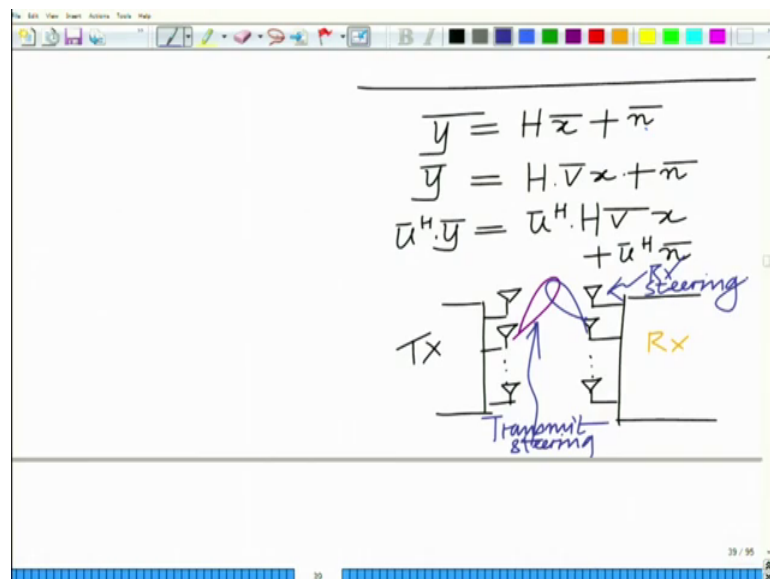

(Refer Slide Time: 15:28)

And now \bar{u} is simply \tilde{u} divided by norm of \tilde{u} which is principal eigenvector with unit norm remember you can simply scale the eigenvector by any quantity it will still be an eigenvector. So, this is the you can say principal eigenvector of HH^H Hermitian with this is a principal eigenvector of HH^H Hermitian with unit norm great.

And therefore, that basically gives us both the transmit and receive beamformers and we have very interesting expressions for them the transmit beamformer \bar{u} optimal transmit beamformer.

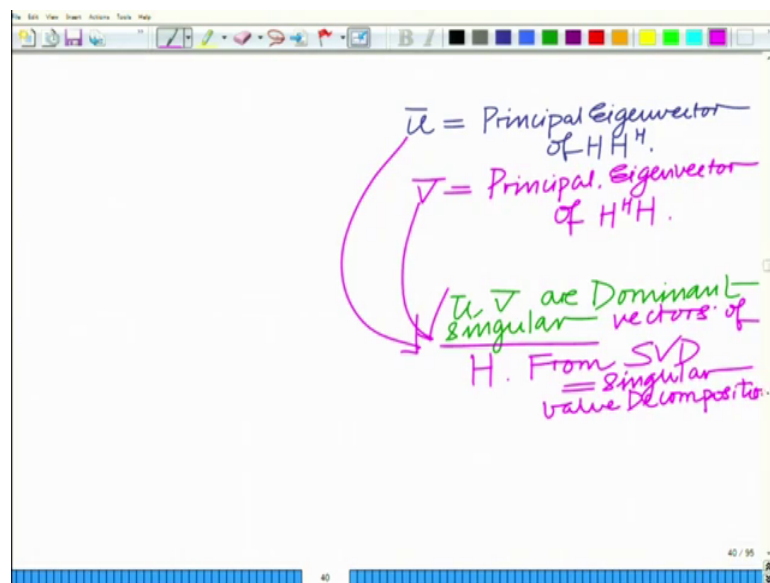

(Refer Slide Time: 16:32)

So, to summarise you have the MIMO Beamforming problem $\bar{y} = H \bar{x} + \bar{n}$ where \bar{x} is transmitted signal, \bar{y} is received signal, and \bar{n} is noise. At the receiver you perform $\bar{u}^H \bar{y}$ which is $\bar{u}^H H \bar{x} + \bar{u}^H \bar{n}$.

And remember what you are doing here is as I already told you have to perform beamforming at both the ends in the MIMO system. So, you have the transmitter you have the receiver your transmitting from the transmitter in a particular direction at the receiver your also collecting or your also processing the signal your steering the receiver antenna array in a particular direction. So, this is basically you are transmit steering remember these all electronic steering so you do not need to physically steer and this is your receive steering.

(Refer Slide Time: 18:03)

And \bar{u} equals eigenvector of $H H^H$ Hermitian corresponding to larger eigenvalue or principal $H H^H$ Hermitian and \bar{v} equals principal eigenvector of $H^H H$ Hermitian H . Now later what we will see is we will see what is known as the singular value decomposition of the channel matrix and it will turn out that \bar{u} and \bar{v} are in fact, the dominant left singular and right \bar{u} is the dominant left singular vector which means singular vector corresponding to the larger singular value.

And similarly \bar{v} is the dominant right singular vector singular vector corresponding to larger singular value. In fact, we will see later that is \bar{u}, \bar{v} are the dominant

singular and this is a key phrase not eigenvectors, but singular vectors of H from the SVD what we call not the EVD from the SVD which is called the singular value decomposition. From the singular value decomposition and further from the singular value decomposition and remember dominant singular values means corresponding to largest singular value.

(Refer Slide Time: 20:02)

Dominant singular vector means corresponding to the largest singular value and in this context also we have seen a very interesting optimization problem that is if you take a positive semi definite matrix $\bar{x}^T A \bar{x}$ maximise subject to the constraint $\|\bar{x}\| \leq 1$. Then \bar{x} equals principal eigenvector provided A is positive semi definite remember $\bar{x}^T A \bar{x}$ provided A is PSD positive semi definite matrix provided \bar{x} is a positive semi definite matrix this is a principal eigenvector of A that is a maximum $\bar{x}^T A \bar{x}$.

Now similarly if you minimise, now this is another interesting analogue. Now, this problem is convex minimise $\bar{x}^T A \bar{x}$ such that $\|\bar{x}\| \geq 1$ of course, this is not convex again in the sense that the constraint is not convex $\|\bar{x}\| \geq 1$, then \bar{x} equals eigenvector corresponding to smallest eigenvalue.

(Refer Slide Time: 21:57)

max. $\|\bar{x}\| \leq 1$ matrix
s.t. $\bar{x} = \text{Principal Eigenvector of } A$

min $\bar{x}^T A \bar{x}$
 $\|\bar{x}\| \geq 1$
 $\bar{x} = \text{Eigenvector corresponding to smallest eigenvalue.}$

So, there are there is a analog this problem eigenvector corresponding to \bar{x} equals eigenvector corresponding to the smallest eigenvalue. And therefore, this is a very interesting application as we have seen here that is basically with respect to beam forming in MIMO system to determine the top table transmit and receive the unit norm transmit and receive beamformers which are given as \bar{v} optimal transmit beamformer is the principal eigenvector of H Hermitian H or you can also say the dominant left singular vector of H .

And \bar{u} is the principal eigenvector of $H H$ Hermitian that is the dominant left singular vector of H , the channel matrix H is the channel matrix of the MIMO wireless system alright. So, with this interesting observation or this completing after completing this interesting example we will stop here and we will continue in the subsequent modules.

Thank you very much.
