**Lecture – 66**  
**Karush-Kuhn-Tucker (KKT) conditions**

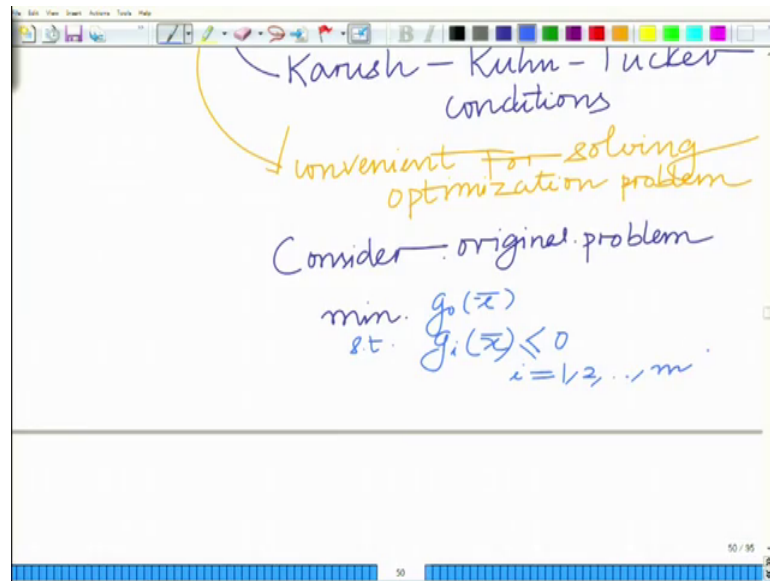

Hello, welcome to another module in this massive open online course. In this module you want to start looking at KKT conditions. So, the Karush-Kuhn-Tucker conditions, which are convenient for solving any optimization problem alright.

(Refer Slide Time: 00:28)

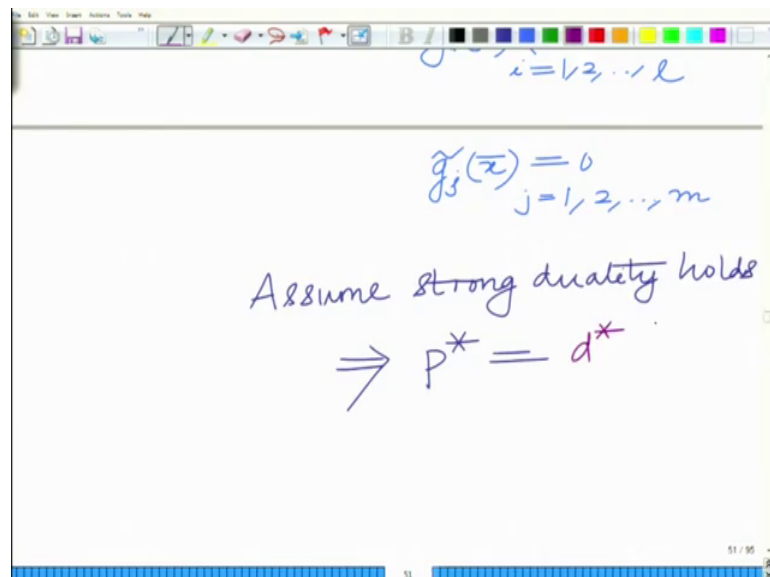

So, what you want us to start looking at is an important of play or aspect of optimization also termed as KKT conditions. Also termed as KKT conditions and these I am sorry, these are the KKT conditions which are also termed as which basically short for the Karush Kuhn or Kuhn Tucker. The Karush-Kuhn-Tucker conditions and these are convenient for solving optimization problem.

(Refer Slide Time: 01:38)

So, now consider again the original or the final optimization problem, consider the original problem what we have is remember we have minimize  $g_0$  of  $\bar{x}$  subject to  $g_i$  of  $\bar{x}$  is equals to 0,  $i$  is equals to 1, 2 up to  $m$  and  $g_j$  tilde of  $\bar{x}$  equals 0 and I am sorry,  $i$  equals to 1, 2 up to  $l$ ,  $g_j$  tilde  $\bar{x}$  equal to 0,  $j$  equals to 1, 2 up to  $m$ .

(Refer Slide Time: 02:13)

And in addition assumed that strong duality holds. Let us assume that strong duality holds, which implies at  $P^*$  is equal to  $d^*$ . Now we know what mean by strong duality. Strong duality employs that  $P^*$  which is the optimal value of the original that

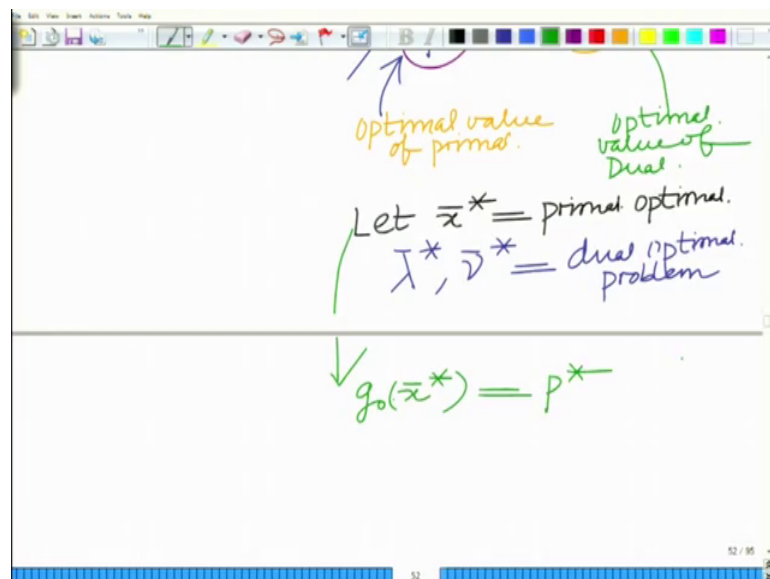

is the primal optimisation problem equals  $d^*$ , which is the optimal value of the dual optimization problem alright. Where the dual cost function of the dual objective function  $g(\lambda)$  maximizes subject to constraint  $\lambda_j \geq 0$ , you get the dual optimal value  $d^*$ . And if strong duality holds then  $P^*$  equals to  $d^*$  ok.

(Refer Slide Time: 03:29)

So,  $P^*$  is optimal value of primal problem and  $d^*$  is basically your optimal value of the  $d$  value; optimal value of the dual optimization ok.

(Refer Slide Time: 04:04)

Now, let  $x^*$  now in addition let  $\bar{x}$  equals primal optimal problem or the primal optimal solution, and that is where the optimal values achieved for the primal optimization problem. That is  $\bar{x}$  is the solution of the primal optimization problem.

Similarly, let  $\bar{\lambda}$  and  $\bar{\nu}$  equals the optimal value and not the optimal value that is the solution of the dual optimal problem that is where the dual optimal is achieved ok. Then by strong duality then by duality or rather strong duality, so we have so basically what this means is, that is if you look at the objective value  $g_0$  at  $\bar{x}$  that is equals to  $P^*$ .

(Refer Slide Time: 05:38)

$$g_d(\bar{\lambda}^*, \bar{\nu}^*) = d^*$$

Strong Duality

$$\Rightarrow P^* = d^*$$
$$\Rightarrow g_0(\bar{x}^*) = g_d(\bar{\lambda}^*, \bar{\nu}^*)$$

And if you look at the value of the optimization the dual objective function at  $\bar{\lambda}$  and  $\bar{\nu}$ , this will be the dual optimal value that is this term there is a optimal value of the dual optimization problem alright. So, they are  $P^*$  and  $d^*$ .

And now from strong duality, we have already said this implies  $P^*$  equals to  $d^*$ , which implies that  $g_0$  of  $\bar{x}$  equals the dual function  $g_d$  of  $\bar{\lambda}$  and  $\bar{\nu}$ .

(Refer Slide Time: 06:39)

The image shows a whiteboard with handwritten mathematical equations. At the top, it states  $\Rightarrow g_0(\bar{x}^*) \equiv g_0(\bar{\lambda}, \bar{\nu})$ . Below this, it shows  $= \min_{\bar{x}} \mathcal{L}(\bar{x}, \bar{\lambda}, \bar{\nu})$ . The next line is  $= \min_{\bar{x}} g_0(\bar{x}) + \sum_{i=1}^l \lambda_i^* g_i(\bar{x})$ . The final line, separated by a horizontal line, is  $+ \sum_{j=1}^m \nu_j^* \tilde{g}_j(\bar{x})$ . The whiteboard has a toolbar at the top and a footer at the bottom right showing '53 / 95'.

Now  $g$  is naught; now, if you look at this  $g$  of  $\bar{\lambda}$  and  $\bar{\nu}$ , now dual function remember, the dual function is the infimum of the Lagrangian, alright.

So, the dual function  $g$  is nothing but the infimum with the Lagrangian over the set of all feasible points  $\bar{x}$ , alright. So, this is basically or infimum or basically is the minimum ok. And this is not the minimum over  $\bar{x}$  of  $g_0(\bar{x}) + \sum_{i=1}^l \lambda_i^* g_i(\bar{x}) + \sum_{j=1}^m \nu_j^* \tilde{g}_j(\bar{x})$  of  $\bar{x}$  ok.

So,  $g$  of  $\bar{\lambda}^*$  and  $\bar{\nu}^*$  is nothing but the infimum of the Lagrangian over all  $\bar{x}$  at  $\bar{\lambda}^*$  and  $\bar{\nu}^*$  ok. So, that is the key argument here this transaction ok. Now once you realize that the rest of the argument is very simple.

(Refer Slide Time: 08:28)

$$\leq g_0(\bar{x}^*) + \sum_{i=1}^l \lambda_i^* g_i(\bar{x}^*) + \sum_{j=1}^m \nu_j^* \tilde{g}_j(\bar{x}^*)$$

Now, if you look at this, this is the minimum over all  $\bar{x}$ , which means this is less than or equal to; so remember the optimal value of this is the minimum over all  $\bar{x}$  which means this is less than or equal to its value corresponding to  $\bar{x}^*$  ok. So, this is less than because,  $\bar{x}^*$  is one particular  $\bar{x}$  that belongs to feasible set ok. So, therefore, this is less than or equal to  $g_0(\bar{x}^*) + \sum_{i=1}^l \lambda_i^* g_i(\bar{x}^*) + \sum_{j=1}^m \nu_j^* \tilde{g}_j(\bar{x}^*)$ , which is less than or equal to  $g_0(\bar{x}^*)$ .

(Refer Slide Time: 09:38)

$$g_0(\bar{x}^*) \leq g_0(\bar{x}^*)$$

$\Rightarrow$  All intermediate quantities must equal  $g_0(\bar{x}^*)$ .

And now if you look at this quantity; now look at this again  $\bar{x}$  is the optimal value belongs to the feasible set satisfy the constraints implies this is equal to 0 which implies this is equals to 0. So, this is equal to 0. Now this again  $\lambda_i^*$  remember is greater than or equal to 0,  $g_i(\bar{x})$  belongs to feasible set  $\bar{x}$  belongs to feasible set. So, this is less than equal to 0. So, this is less than or equal to 0.

So, this is less than or equal to  $g_0(\bar{x})$ . And therefore, now you have very interesting observation. You have started from  $g_0(\bar{x})$ , you have ended with  $g_0(\bar{x})$ , which are indeed equal this implies all the intermediate quantities. So, you have left  $g_0(\bar{x})$  less than equal to right  $g_0(\bar{x})$  which are nothing but one and the same; which means all the intermediate quantities which are sandwiched in between must be also equal to  $g_0(\bar{x})$  ok.

So, which means that all intermediate quantities must equal, this is very simple for instance, we are in equality 5 less than or equal to  $x$  less than equal to  $y$  less than equal to 5. So, remember the end we have 5, 5 and  $x$  less than equal to  $x$ ,  $x$  less than equal to 5. This is only one possibility that is  $x$  equals 5,  $y$  equals 5.

So, all the intermediate quantities; so similarly if you follow this chain of arguments towards both an  $g$  and  $g_0(\bar{x})$ , which means all the intermediate quantities must be  $g_0(\bar{x})$ .

(Refer Slide Time: 12:04)

The whiteboard shows the following handwritten text and equations:

$$\bar{x} = 5$$

$$\bar{y} = -5$$

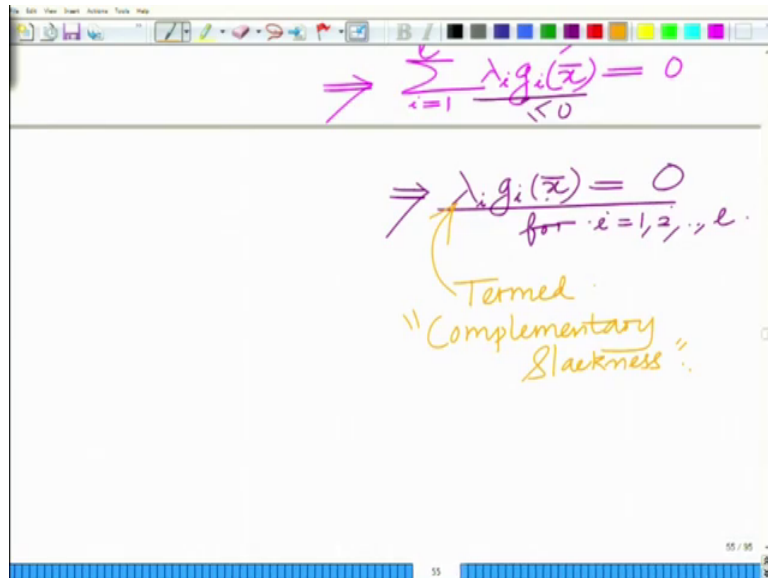

in particular,

$$\cancel{g_0(\bar{x}^*)} + \sum_{i=1}^l \lambda_i^* g_i(\bar{x}^*) + \sum_{j=1}^m \tilde{\lambda}_j^* \tilde{g}_j(\bar{x}^*) = \cancel{g_0(\bar{x}^*)}$$

The final result is  $= 0$ .

And therefore, this implies in particular we must have  $\sum_{i=1}^l \lambda_i g_i(\bar{x}) = 0$ . Now if you cancel these things  $\lambda_i g_i(\bar{x}) = 0$  we know this is 0 anyway.

(Refer Slide Time: 12:59)

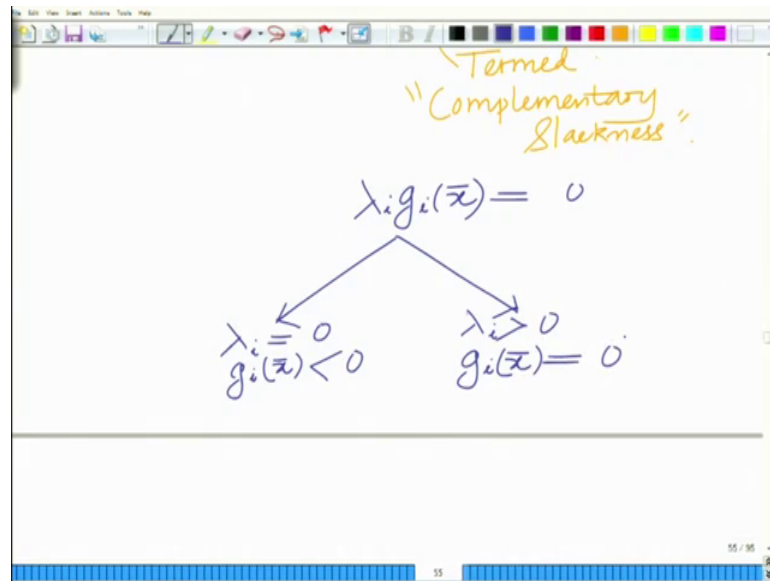

So, this implies that the only remaining term that is  $\sum_{i=1}^l \lambda_i g_i(\bar{x}) = 0$ . Now remember each of this quantity as  $\lambda_i g_i(\bar{x}) \leq 0$ , the sum of several non positive quantities is equal to 0 which means each of this quantities is equal.

You remember each of this quantity is less than equal to 0, but there some is equals to 0 which means each of these quantities equals to 0. This implies  $\lambda_i g_i(\bar{x}) = 0$  for each  $i$ , for  $i$  equals to 1, 2 up to  $l$ . And this is the very interesting property this is termed as complimentary slackness and I am going to explain this in a movement, this is termed interesting name. The meaning of this is following this implies  $\lambda_i g_i(\bar{x}) = 0$  which implies either.

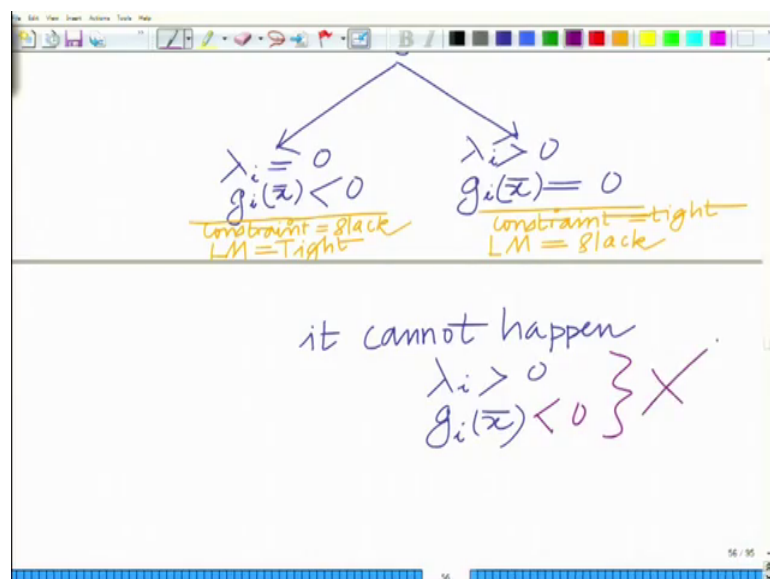

(Refer Slide Time: 14:18)

So, we have  $\lambda_i g_i(\bar{x}) = 0$ . So, this implies 2 things either  $\lambda_i = 0$  correct, which means  $g_i(\bar{x}) < 0$  or  $\lambda_i > 0$  and  $g_i(\bar{x}) = 0$ .

(Refer Slide Time: 15:04)

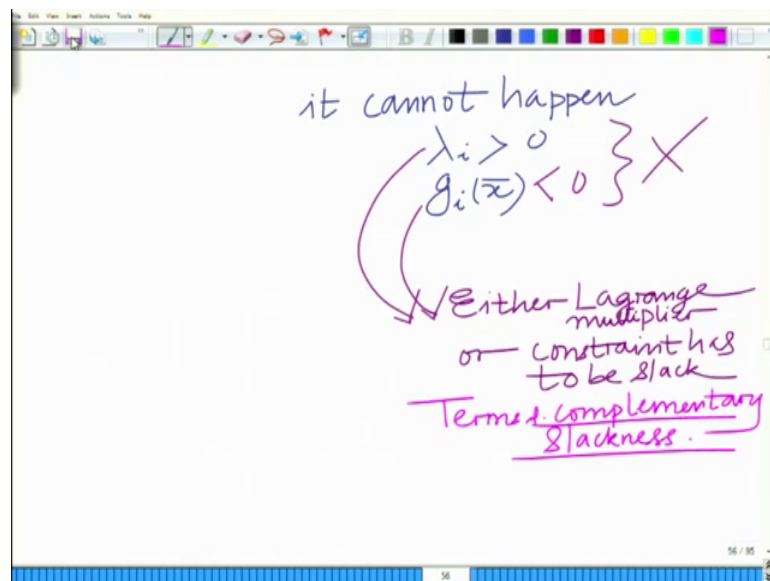

So, in this case now let us look at this in this case, the constraint is tight, it is met with equality. And Lagrange multiplier LM equals slack that is greater than. Now in this case the constraint is slack  $g_i(\bar{x}) < 0$ , so there is some slack ok,  $g_i(\bar{x}) < 0$

than 0, which means whatever is  $g_i(\bar{x}) - 0$  that is the slack, so the constraint is slack.

And LM Lagrange multiplier equals tight because, the Lagrange multiplier equals 0. So, this is the meaning of the complimentary slack that is either the Lagrange multiplier is slack or the constraint is slack. It cannot happen that both the Lagrange multiplier and the constraint are slack; that is it cannot happen that  $\lambda_i$  is greater strictly greater than 0 and  $g_i$  of  $\bar{x}$  is strictly less than 0, this cannot happen because  $\lambda_i$  into  $g_i$  of  $\bar{x}$  must equals ok.

So, it cannot happen that  $\lambda_i$  is greater than 0  $g_j$  or  $g_i$  of  $\bar{x}$  is strictly less than 0 this is not possible.

(Refer Slide Time: 16:41)

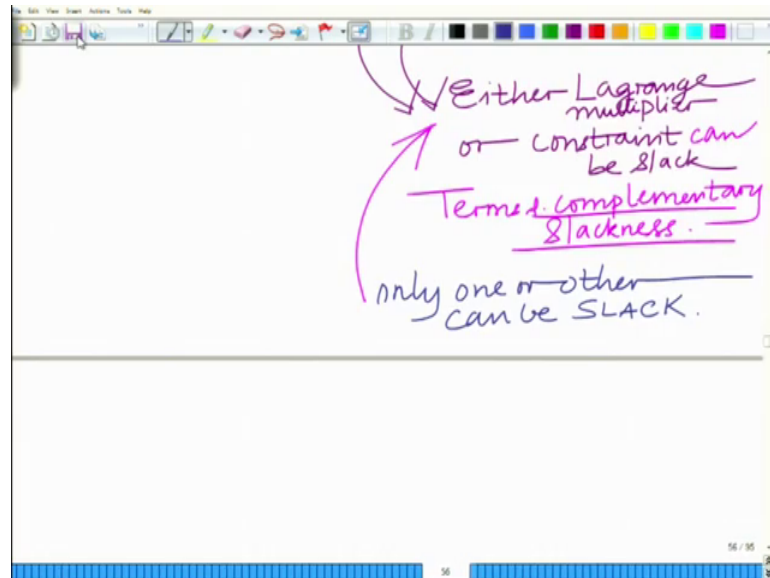

Which means either constraint or Lagrange multiplier has to be slack this termed as to be complimentary slack. So, these complement each other; either Lagrange multiplier or constraint ok.

This is termed this termed as complimentary. This property is termed as complimentary slackness. And this is a unique aspect of the KKT conditions that is that is the both cannot be and both cannot be that is cannot happen that Lagrange multiplier is strictly greater than 0. The constraint inequality constraint is less than 0, it can only happen only that only one of them is slack, let the other is 0.

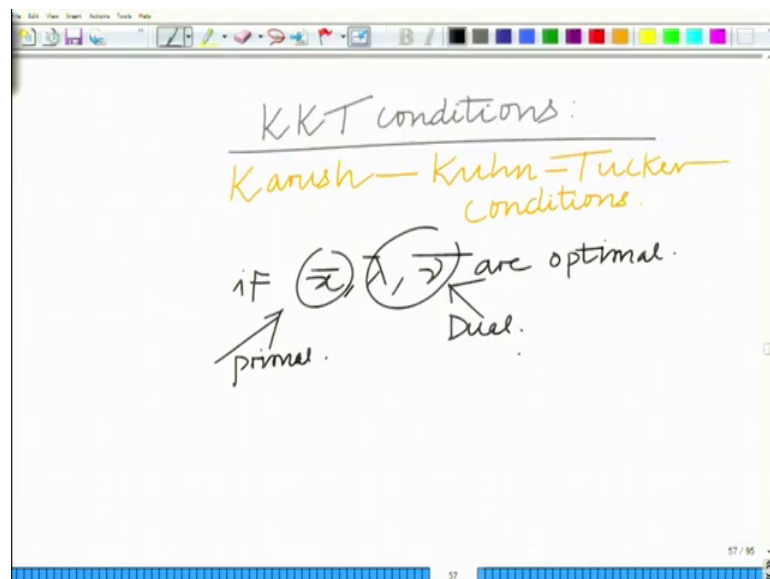

So, the Lagrange multiplier is 0, the constraint is slack, is the constraint is 0, the Lagrange multiplier is slack and this is known as complimentary slack. So, only one or the can be slack ok, termed only either Lagrange multiplier or constraint can be slack, not has to be slack, can be slack, only one or other can be slack.

(Refer Slide Time: 18:24)

Only one or the other can be slack. That is basically your complimentary slackers. And the KKT conditions can be finally, stated as follows; the Karush-Kuhn-Tucker conditions.

(Refer Slide Time: 18:55)

These are your Karush the Karush-Kuhn-Tucker. And the KKT conditions are basically if  $\bar{x}$   $\bar{\lambda}$   $\bar{\nu}$  are optimal, that is a  $\bar{x}$  for obviously the primal problem, this is for the primal and this is for the dual and strong duality holds.

(Refer Slide Time: 20:05)

Conclusion:

If  $(\bar{x}, \bar{\lambda}, \bar{\nu})$  are optimal.  
 $\bar{x}$  is primal.  $(\bar{\lambda}, \bar{\nu})$  is Dual.  
 & Strong duality holds.  
 $\Rightarrow g_0(\bar{x}) = g_0(\bar{\lambda}, \bar{\nu})$   
 must satisfy the KKT conditions.

---

Then:

1. Primal Constraints

57 / 95

And strong duality holds, this implies that your  $g$  naught of  $\bar{x}$  equals  $g$  d of  $\bar{\lambda}$   $\bar{\nu}$ .

(Refer Slide Time: 20:34)

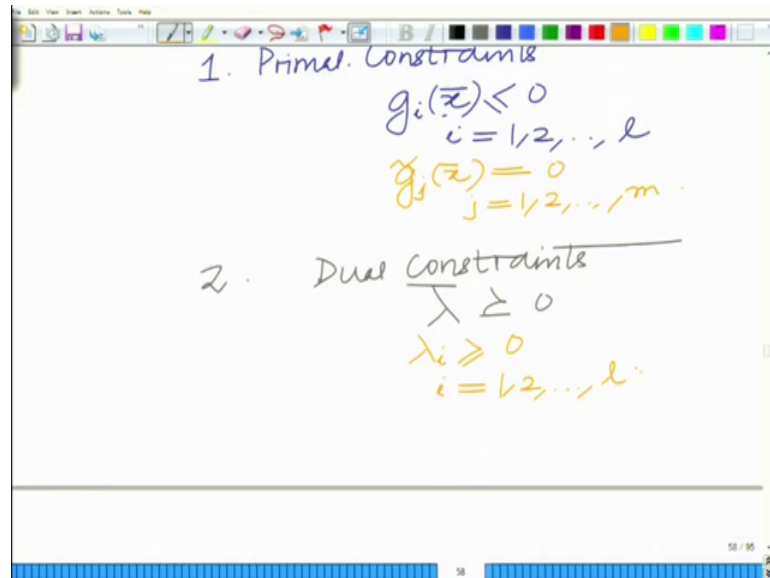

Then:

1. Primal Constraints
  - $g_i(\bar{x}) \leq 0$   
 $i = 1, 2, \dots, l$
  - $\gamma_j(\bar{x}) = 0$   
 $j = 1, 2, \dots, m$

58 / 95

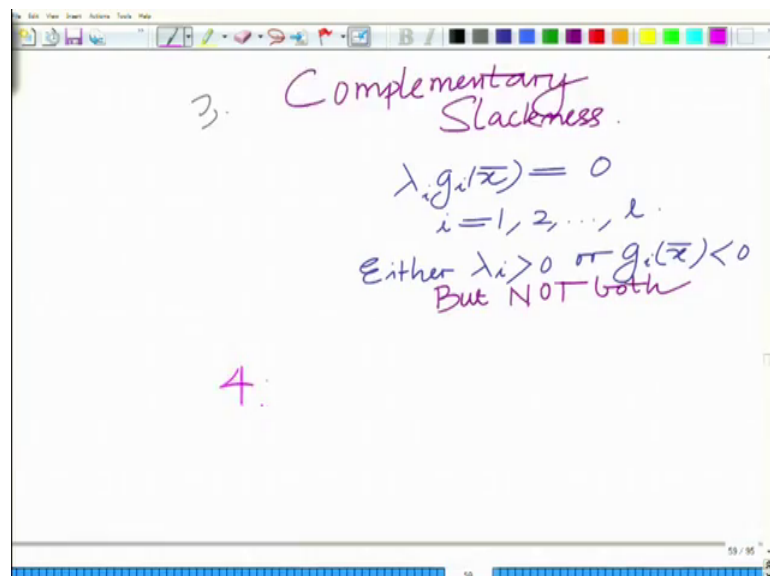

Then it must be that; then first we have the primal constraints, these must hold. The primal constraints are basically  $g_i(\bar{x}) \leq 0$  for  $i = 1, 2, \dots, l$ ,  $g_j(\bar{x}) = 0$  for  $j = 1, 2, \dots, m$ .

(Refer Slide Time: 21:13)

The dual constraints must hold. What are the dual constraints? Remember  $\lambda$  is component wise greater than equals to 0 which implies each  $\lambda_i$  is greater than equal to 0, for  $i = 1, 2, \dots, l$  that is Lagrange multipliers associated with the inequality constraints are greater than or equals to 0, alright.

(Refer Slide Time: 21:45)

Complimentary slackness, this is the third condition. Complimentary slackness what happens in complimentary slackness, we have with respect Lagrangian, with respect to the gradient, with respect to the Lagrangian equals 0.

This implies that, the gradient of the Lagrangian vanishes that this implies basically the gradient with respect to  $\bar{x}$  because, remember at  $\bar{x}$  this is the infimum of the Lagrangian correct, this optimal value  $\bar{x}$  we have the infimum of the Lagrangian; which means the gradient we have the minimum of the Lagrangian function. Therefore, the gradient with respect to  $\bar{x}$  of the Lagrangian has to vanish at  $\bar{x}$  ok. Plus I am sorry, this is not complimentary slackness, complimentary slackness let me just mention the complimentary slackness aspect this will come later.

So, the complimentary slackness we have already seen that. That is  $\lambda_i g_i(\bar{x}) = 0$ ,  $i = 1, 2, \dots, l$ , that is either  $\lambda_i = 0$  or  $g_i(\bar{x}) = 0$  or  $\lambda_i > 0$  or  $g_i(\bar{x}) < 0$ . That is either a slack, but not both either a slack but not both.

And finally, since  $\bar{x}$  is the infimum or at  $\bar{x}$  you have the minimum of the Lagrangian, of the Lagrangian function Lagrangian of  $\bar{x}$   $\bar{\lambda}$   $\bar{\nu}$ .

(Refer Slide Time: 24:32)

$\lambda_i g_i(\bar{x}) = 0$   
 $i = 1, 2, \dots, l$   
 Either  $\lambda_i > 0$  or  $g_i(\bar{x}) < 0$   
 But NOT both

4.  $\nabla_{\bar{x}} \mathcal{L}(\bar{x}, \bar{\lambda}, \bar{\nu})$   
 $= \nabla_{\bar{x}} g_0(\bar{x}) + \sum_{i=1}^l \lambda_i \nabla_{\bar{x}} g_i(\bar{x})$   
 $+ \sum_{j=1}^m \nu_j \nabla_{\bar{x}} \hat{g}_j(\bar{x}) = 0$

The gradient with respect to  $\bar{x}$  of the Lagrangian must vanish at this point  $\bar{x}$ . That is we must have delta the gradient of the respective  $\bar{x}$   $g$  naught  $\bar{x}$  plus summation

$i$  equal to 1 to  $l$ , gradient with respect to  $i$ ,  $g$  of  $\bar{x}$  plus summation  $g$  equals 1 to  $m$   $\nu_j$ , the gradient with respect to  $x$  of  $g_j$   $\tilde{x}$   $\bar{x}$ , this must be equal to 0, alright. And these are the KKT conditions and if these are  $\bar{x}$   $\bar{\lambda}$   $\bar{\nu}$  are the optimal solutions of the primal, and the dual optimization problems  $\bar{x}$   $\bar{\lambda}$ , and strong duality holds  $\bar{x}$   $\bar{\lambda}$   $\bar{\nu}$  must satisfy must satisfy the KKT conditions ok. So, these are the 4 KKT conditions that must be satisfied by the solution solutions  $\bar{x}$  of the  $\bar{x}$  of the primal optimization problem and  $\bar{\lambda}$   $\bar{\nu}$  of the dual optimization alright.

So, let us stop here and continue in the subsequent modules.

Thank you very much.
