Lecture – 34
Automatic generation control conventional scenario (Contd.)

(Refer Slide Time: 00:21)

$$\therefore \frac{\Delta P_g}{P_r} - \frac{\Delta P_L}{P_r} = \frac{2H}{f_0} \frac{df}{dt} + \frac{D}{P_r} \Delta f$$

$$\therefore \Delta P_g(\text{pu}) - \Delta P_L(\text{pu}) = \frac{2H}{f_0} \frac{df}{dt} + D(\text{pu}) \Delta f \quad \text{---(12.10)}$$

Taking the Laplace transform of eqn (12.10), we get

$$\Delta f(s) = \frac{\Delta P_g(s) - \Delta P_L(s)}{D + \frac{2H}{f_0} s}$$

Now, we are back again. So, taking the Laplace transform on equation-10 right. If you take the Laplace transform and simplify, then you will get $\Delta f s$ is equal to $\Delta P_g S$ minus $\Delta P_L S$ divided by D plus $2H$ upon f_0 into S right. Later what we will do, these are all per unit, these are all per unit, so again and again here, here, so no and here will not mention the per unit again and again right, so but it is understandable. I mean from this point onwards everything is in per unit. If anything is real unit, it will be discussed, so this is your Δf .

(Refer Slide Time: 01:05)

Taking the Laplace transform of eqn (12.10), we get

$$\Delta f(s) = \frac{\Delta P_g(s) - \Delta P_L(s)}{D + \frac{2H}{f_0}s} = \frac{(\Delta P_g - \Delta P_L)}{D}$$

$$\therefore \Delta f(s) = [\Delta P_g(s) - \Delta P_L(s)] \times \frac{K_p}{(1 + ST_p)} \quad 2 + \frac{2H \cdot s}{f_0 D} \quad (12.11)$$

where

$$T_p = \frac{2H}{Df_0} = \text{power system time constant}$$

$$K_p = \frac{1}{D}$$

$$K_t = 1 = \text{Gain of power system}$$

$$T_p = \frac{2H}{f_0 D}$$

Now, this one, if you simplify, basically $\Delta f(s)$ will be $\Delta P_g(s) - \Delta P_L(s)$ into K_p upon $1 + ST_p$ that means, actually T_p is these equation these equation right whatever it is, these equation a numerator and denominator you divide by D . So, this can be written as $\Delta P_g(s) - \Delta P_L(s)$ is understandable put it minus $\Delta P_L(s)$ right divided by D , then divided it also [numerator/denominator] denominator also divided by D , so it will be $1 + 2H$ upon $f_0 D$ into S right.

So, we assume K_p if you assume K_p is equal to $1/D$, say let K_p is equal to $1/D$, and T_p is equal to $2H$ upon your f_0 into D right. This is your $f_0 D$, this is your T_p that means, this equation can be written as $\Delta P_g(s) - \Delta P_L(s)$ into K_p upon $1 + ST_p$ right.

(Refer Slide Time: 02:20)

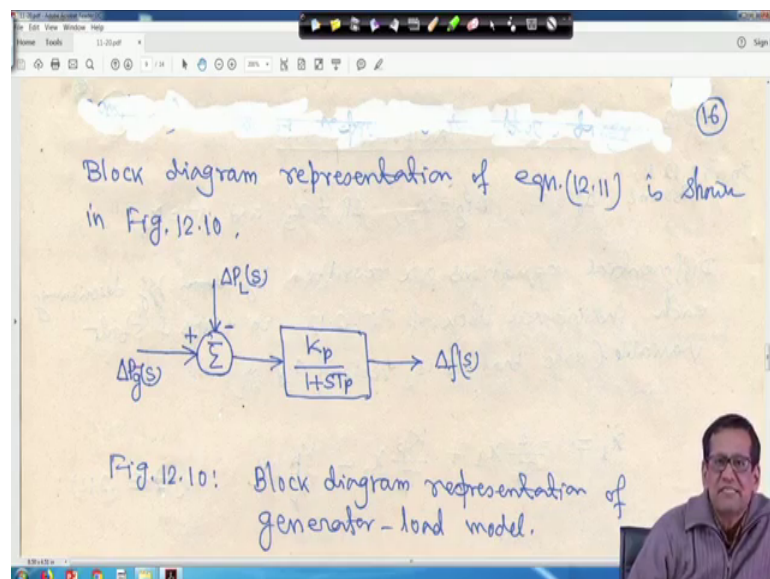

$$\Delta f(s) = \frac{\Delta P_g(s) - \Delta P_L(s)}{D + \frac{2H}{f_0} s}$$
$$\therefore \Delta f(s) = \left[\Delta P_g(s) - \Delta P_L(s) \right] \times \frac{K_p}{(1 + sT_p)} \quad \text{--- (12.11)}$$

where

$$T_p = \frac{2H}{Df_0} = \text{power system time constant}$$
$$K_p = \frac{1}{D} = \text{Gain of power system.}$$

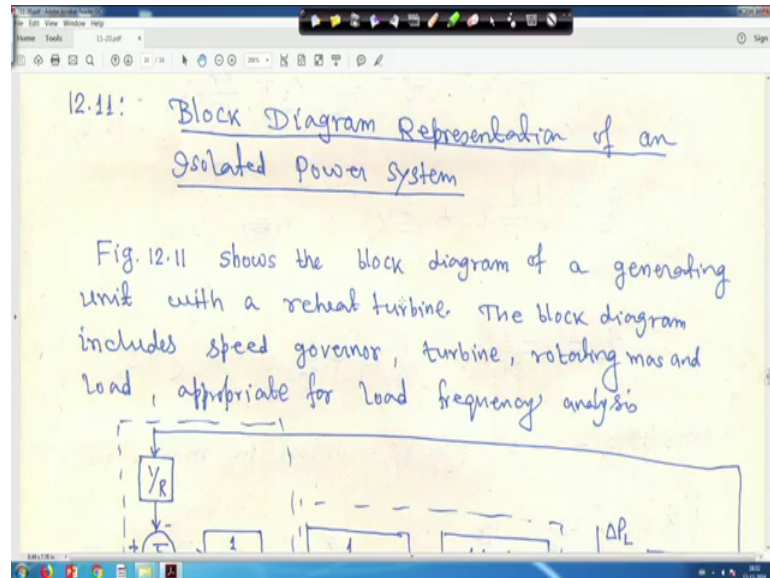

So, T_p actually we call is a power system time constant, this is your this one is your power system time constant. And K_p is equal to $1/D$ is equal to gain of power system, this way we define this one right. So, so transfer function for that I mean generator load this relationship in between your generate generating power load, and that frequency deviation now has been completed right.

(Refer Slide Time: 02:49)

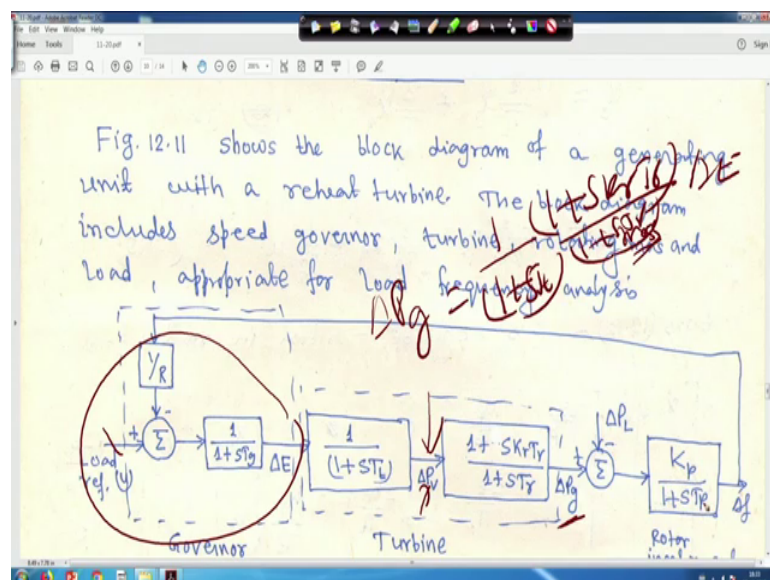

Now, that means for this portion I mean this equation that equation-11, this equation you can make it like this kind of block diagram $\Delta P_g - \Delta P_L = K_p \frac{1}{1 + ST_p} \Delta f$. So, this way we can go for block diagram representation right.

(Refer Slide Time: 03:08)

So, now so block diagram representation of an isolated power system.

(Refer Slide Time: 03:16)

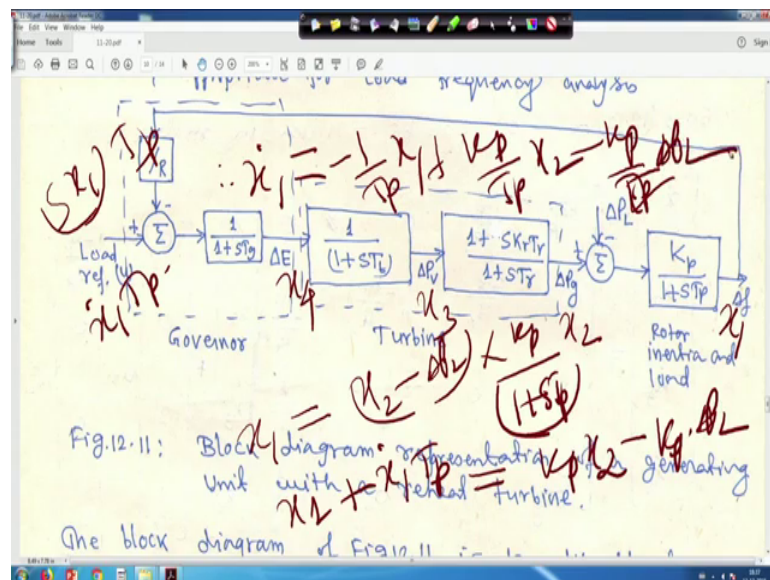

Now, what you have done the figure-11 shows the block diagram of a generating unit with a reheat turbine. The block diagram include speed governor, turbine, rotating your

what to you call rotating mass right rotating mass, and your hold on is rotating mass, and load right, appropriate for load frequency analysis.

So, we have seen that how to link that modeling, it is basically modeling how to link. So, this is my governor, this is load reference set point. And we have seen also that your delta your what you call that 1 plus S T t and it is your what to you call this intermediate point, we are making your delta P V, because we have seen when we try to develop that you are what to you call reheat turbine modeling. So, we have seen that delta P g is equal to 1 upon 1 plus S T t into your 1 plus S K r T r divided by 1 plus S T r right into your delta E.

So, we have to make it in state variable form so these two blocks split it right. And in between this one state variable is taken that is delta P V. And this is delta P g is already output is there, and minus P L into K p upon 1 plus S T p right. And that is your delta f, but if this delta feedback has come here 1 upon R, this minus this is plus right. So, this part actually is a governor part right. And this part is actually turbine part, and this is actually power system part we call right.

(Refer Slide Time: 05:11)

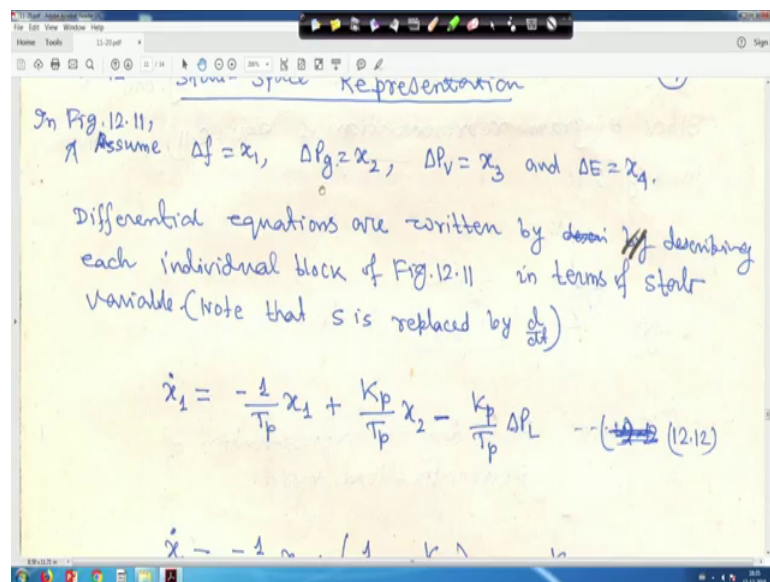

So, so this is so this is rotor inertia and load together we call this is actually power system part power system right. So, this is if you look into that if you to look into that there are four-state variable, this is one, this is one two, this is three, and this is four, there are four-state variable right.

So, we have to write down those equation in the state space form, so that mean x 1 dot, x 2 dot like this. So, if it if you just one minute, if you want to I mean just over writing on it, if you want that you are only non-reheat turbine, then this block should not be there for non this will directly we delta P g.

In that case, you will have three-state variable this one, this one, and this one. If you do not consider reheat, if you consider only non-reheat turbine, then only three you are what you call that you are three block should be there, this one, this one, and this one. And this is actually delta P g output, this should not be there right this block should not be there. So, now state variable analysis, we have to go for their right.

(Refer Slide Time: 06:33)

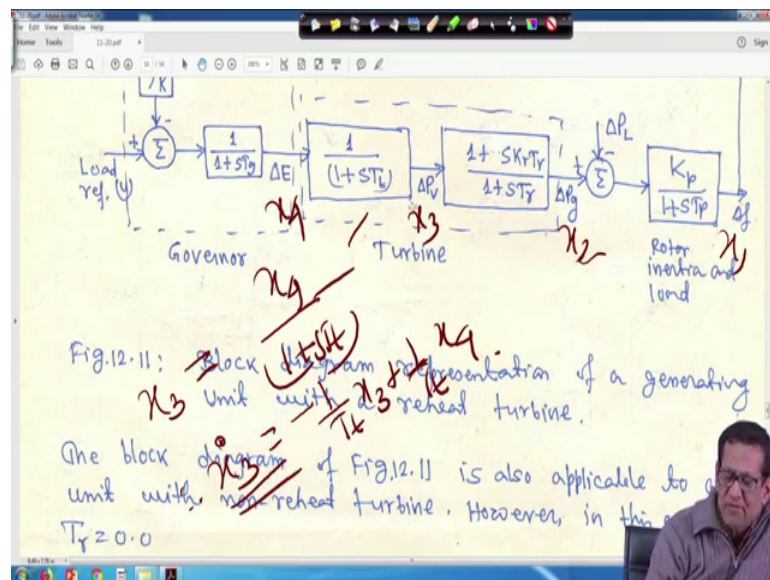

So, so delta f we have taken x 1, delta P g x 2, delta P V x 3, and delta E is equal to x 4. Now, we have taken just one I am showing, other I think you can do it. One assuming all initial conditions are 0, this is x 1, this delta f x 1, this is my x 2, this is my x 3, and this is my x 4 right this is given in the next page.

So, when you write this equation state variable equation right, so we can write and this is your load delta P L right. So, you can write I am writing here only all over writing on it, I think it you can see it x 1 is equal to this is x 2, and this is plus x 2 minus delta P L into K p upon 1 plus S T p right.

So, now if you cross multiply, so it will be x^{-1} it will be x^{-1} plus it is $S \times 1$, here I am writing separately $S \times 1$ into $T \times p$. But, $S \times 1$ is nothing but x^{-1} dot right, so it is nothing but x^{-1} dot into $T \times p$ right. So, $S \times 1$, it is nothing but x^{-1} dot into $T \times p$ right is equal to this is your what you call this is your $K_p \times 2$ minus K_p into $\Delta P L$ right.

Therefore, from here you can write your x^{-1} dot, if you write here from x^{-1} dot is equal to this x^{-1} will go to the right hand side and divide by $T \times p$, it will be $\frac{-1}{T \times p} + \frac{K_p}{T \times p} \times 2$ right minus $\frac{K_p}{T \times p}$ your $\Delta P L$. So, this way you can write, so that is why that is why you have written x^{-1} dot is equal to your $\frac{-1}{T \times p} + \frac{K_p}{T \times p} \times 2$ minus $\frac{K_p}{T \times p}$ $\Delta P L$ equation this is 12 right.

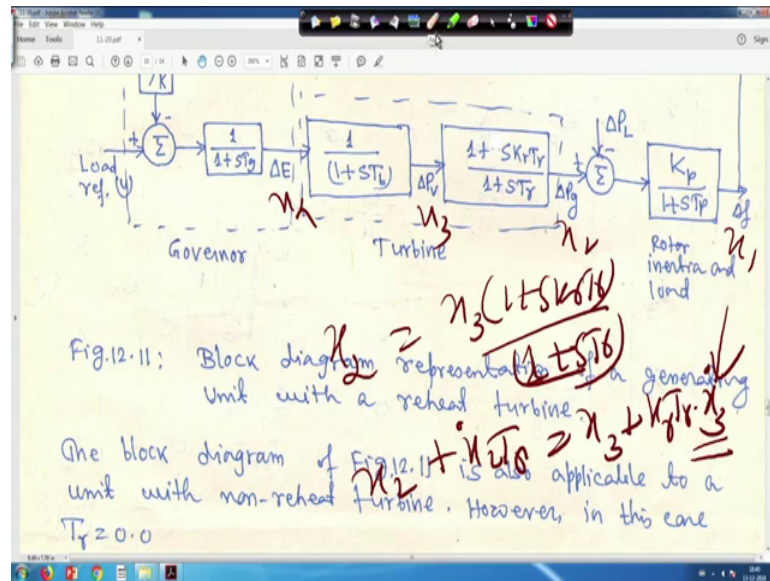

(Refer Slide Time: 08:57)

So, one more I have to show you, because one derivative term is there in the numerator in this block. So, if it is x^{-2} right first thing is that if it is x^{-2} and this is x^{-3} , so what you have to do is for this is x^{-1} , this is my x^{-2} , this is x^{-3} , and this is x^{-4} right.

So, in this case what you will do that x^{-2} is equal to your x^{-3} into this term, but there you need x^{-3} dot will come. So, first what you will do, first find out $x^{-3} \times 3$ dot. So, when you write x^{-3} dot, so x^{-3} is equal to x^{-4} upon $1 + S T t$ I mean this one this block only. If you cross multiply, then it will be x^{-3} dot is equal to we call S into $x^{-3} \times 3$ dot, so x^{-3} dot will be basically $\frac{-1}{T t} x^{-3} + \frac{1}{T t} x^{-4}$ right. So, x^{-3} dot can be obtained from here right.

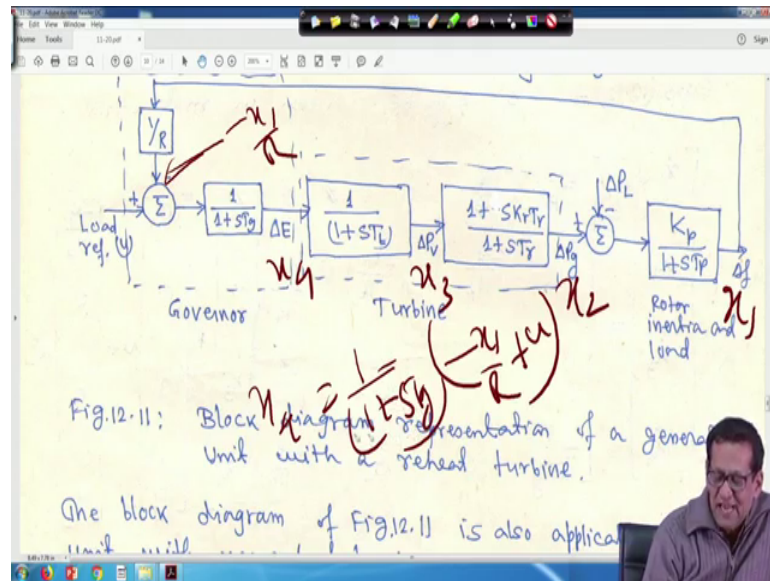

(Refer Slide Time: 09:50)

Next what will do take this equation this is my x_1 , this is x_2 , this is x_3 , and this is x_4 , so x_3 dot we have seen. Now, x_2 is equal to then, this x_3 into $1 + S k_r T_r$ upon $1 + S T_r$ right.

Now, if you cross multiply, it will be x_2 it will be x_2 plus x_2 dot T_r is equal to multiply this one x_3 plus S into x_3 that is x_3 dot that means, $K_r T_r$ into x_3 dot right. So, to eliminate this x_3 dot, you have already got the equation of x_3 dot is equal to minus 1 upon T_t x_3 plus 1 upon T_t x_4 that we will substitute here right such the right hand side will be three of any derivative term right. Then all x_1 , x_2 , x_3 , we will get then x_4 is equal to automatically we will get it right. So, this is for your x_1 , x_2 , x_3 right dot.

(Refer Slide Time: 10:59)

Now, x_4 is this one is your x_4 , this one is your x_4 , this is x_1 again I am writing x_1 , then you will go to that final thing this is x_3 , and this is x_4 right. So, here also x_4 is equal to you can write, this is my u .

And this x_1 is coming here, so here it is minus x_1 upon R right. So, it is basically x_4 , your what you call x_4 is equal to 1 upon $1 + sT_g$ right into minus x_1 upon R plus u right. So, just you have to simplify, and you will get a cross multiplication and you will get the x_4 dot right.

(Refer Slide Time: 11:42)

$$\dot{x}_2 = -\frac{1}{T_r} x_2 + \left(\frac{1}{T_r} - \frac{k_r}{T_t}\right) x_3 + \frac{k_r}{T_t} x_4 \quad \dots (12.13)$$

$$\dot{x}_3 = -\frac{1}{T_t} x_3 + \frac{1}{T_t} x_4 \quad \dots (12.14)$$

$$\dot{x}_4 = -\frac{1}{R T_g} x_1 - \frac{1}{T_g} x_4 + \frac{1}{T_g} u \quad \dots (12.15)$$

So, that is why, we have written that x 1 dot, x 2 dot, your x 3 dot, and x 4 dot. So, these all these equation 12, 13, 14, and 15 right. So, all this equations are written first you derive of your own right.

(Refer Slide Time: 12:13)

Eqs. (12.12) - (12.15) can be written in matrix form:

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \end{bmatrix} = \begin{bmatrix} -\frac{1}{T_p} & \frac{k_p}{T_p} & 0 & 0 \\ 0 & -\frac{1}{T_p} & \left(\frac{1}{T_p} - \frac{k_p}{T_e}\right) & \frac{k_p}{T_e} \\ 0 & 0 & -\frac{1}{T_e} & \frac{1}{T_e} \\ -\frac{1}{RT_g} & 0 & 0 & -\frac{1}{RT_g} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \\ \frac{1}{T_g} \end{bmatrix} u + \begin{bmatrix} -\frac{k_p}{T_p} \\ 0 \\ 0 \\ 0 \end{bmatrix} \Delta P_L$$

Once you get all these equations right, it can be written in the matrix form that is your x 1 dot is equal to x 2 dot, x 3 4 dot all put in this matrix form. So, this is actually 4 into 4 matrix into x 1, x 2, x 3, x 4 plus your all will be all the first three equation no u is present. So, only last one is there that is 1 upon T g u. And all the first equation the delta P L is present, all other equations it is delta P L is not there, so all 0 0 0, this is also 0 0 0, this is 1 upon T g.

(Refer Slide Time: 12:45)

Eqns. (12.12) - (12.15) can be written in matrix form:

$$\begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \\ \dot{x}_3 \\ \dot{x}_4 \end{bmatrix} = \begin{bmatrix} -\frac{1}{T_p} & \frac{k_p}{T_p} & 0 & 0 \\ 0 & -\frac{1}{T_p} & \left(\frac{1}{T_p} - \frac{k_p}{T_b}\right) & \frac{k_p}{T_b} \\ 0 & 0 & -\frac{1}{T_b} & \frac{1}{T_b} \\ -\frac{1}{R T_g} & 0 & 0 & -\frac{1}{T_g} \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \end{bmatrix} + \begin{bmatrix} 0 \\ 0 \\ 0 \\ \frac{1}{R T_g} \end{bmatrix} \begin{bmatrix} -\frac{k_p}{T_p} \\ 0 \\ 0 \\ \frac{1}{T_g} \end{bmatrix}$$

$\dot{X} = AX + BU + Pp$

So, this matrix this matrix we call this matrix is A 1 right, and this is B right, and this is we call gamma right. So, A is a 4 into 4 matrix right, B is 4 into 1, and gamma is 4 into 1 right. So, this equation can be written in this form that x dot is equal to A X plus B U plus gamma p or this gamma rather than do using this this gamma, gamma p right. So, this is actually in the state variable form.

(Refer Slide Time: 13:19)

Eqn. (12.16) can be written as:

$$\dot{X} = AX + BU + Pp \quad \dots (12.17)$$

where

$$x' = [x_1 \quad x_2 \quad x_3 \quad x_4]$$

$$A = \begin{bmatrix} -\frac{1}{T_p} & \frac{k_p}{T_p} & 0 & 0 \\ 0 & -\frac{1}{T_p} & \left(\frac{1}{T_p} - \frac{k_p}{T_b}\right) & \frac{k_p}{T_b} \end{bmatrix}$$

Now, we can write x dot is equal to A X plus B U plus gamma p.

(Refer Slide Time: 13:27)

where

$$x' = [x_1 \quad x_2 \quad x_3 \quad x_4]$$

$$A = \begin{bmatrix} -\frac{1}{T_p} & \frac{K_p}{T_p} & 0 & 0 \\ 0 & \frac{1}{T_p} & \left(\frac{1}{T_p} - \frac{K_p}{T_t}\right) & \frac{K_p}{T_t} \\ 0 & 0 & -\frac{1}{T_t} & \frac{1}{T_t} \\ -\frac{1}{R T_g} & 0 & 0 & -\frac{1}{T_g} \end{bmatrix}$$

So, this is equation-17 or four-state variables are there x_1 , x_2 , x_3 , x_4 , and this is our A matrix right this is A matrix. Now, how you know that system is stable. What will do is that for A matrix, you find out the eigen values. If all the eigen values real part lying on the left top of the explain, then your system is stable right.

(Refer Slide Time: 13:54)

$$\begin{bmatrix} -\frac{1}{R T_g} & 0 & 0 & -\frac{1}{T_g} \end{bmatrix}$$

$$B' = [0 \quad 0 \quad 0 \quad \frac{1}{T_g}]$$

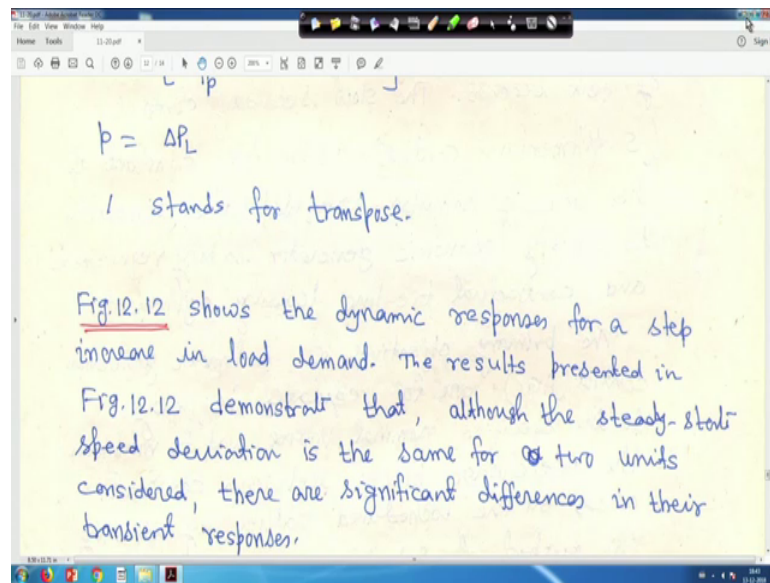

$$\Gamma' = \begin{bmatrix} -\frac{K_p}{T_p} & 0 & 0 & 0 \end{bmatrix}$$

$$p = \Delta P_L$$

t stands for transpose.

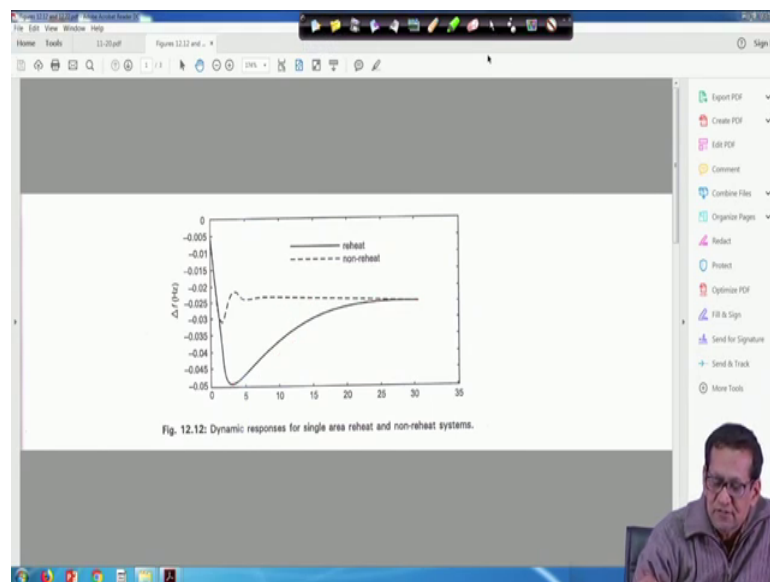

And B dash that is transpose 0 0 0 1 upon T g. And gamma dash that is transpose minus K p upon T p 0 0 0 right. And p is equal to disturbance that is delta P L. So, this equation whenever we are writing your p this p gamma p, p actually is a delta P L right.

(Refer Slide Time: 14:21)

So, so figure-12 shows the dynamic responses for a step increase in load demand. So, I will show you the dynamic response is just hold on right.

(Refer Slide Time: 14:28)

This is actually figure-12. So, this response actually for although steady state error remains same, but this continuous line this is for reheat turbine right. And when that and when the transfer function, you are what you call is drop that 3 into 3 model, this is for non-reheat turbine the dash one right. And frequency deviation for some parameter it is given right reheat and non-reheat.

Steady state value is same, but for reheat case pick deviation is more as compare to the your non-reheat one right, but there steady state value will I mean remain same right. So, this is your this is the diagram. Now, again I will go back to this one. This is our that your what you call A, B dash, and gamma. And this is so I showed you the dynamic responses also right.

(Refer Slide Time: 15:37)

$$\Gamma' = \begin{bmatrix} -\frac{k_p}{T_p} & 0 & 0 & 0 \end{bmatrix}$$

$$p = \Delta P_L$$

$$\dot{x} = Ax + Bu + \Gamma p$$

$$u = 0$$

$$\therefore \dot{x} = Ax + \Gamma p$$

1 stands for transpose.
 $p = \Delta P_L = 0.01 p$

Fig.12.12 shows the dynamic responses for a step increase in load demand. The results presented in Fig.12.12 demonstrate that, although the steady speed deviation is the same for two

Now, another thing is that before moving to that fundamentals of automatic generation control. Another point is that that we know that \dot{x} is equal to $A X$ plus $B U$ plus γp right. And the responses which was shown that is when u is equal to 0, there was no control signal right u is equal to 0 that means, my \dot{x} is equal to $A X$ plus γp . And the responses was shown for p is equal to ΔP_L , and it was taken as a 0.01 per unit 1 percent stay for change right.

Now, you from final value theorem, you can easily find out the steady state your what you call the steady state values right I have for all the state variables, but here also from this equation also when your system is uncontrol, you also you can find out the steady state values how.

(Refer Slide Time: 16:36)

$$A = \begin{bmatrix} -\frac{k_p}{T_p} & 0 & 0 & 0 \end{bmatrix}$$

$$B = \Delta P_L$$

$$\dot{X} = AX + Bp$$

$$X = X_{SS}$$

1 stands for transpose.

$x_{1,ss}, x_{2,ss}, x_{3,ss}$ & $x_{4,ss}$

Fig.12.12 shows the dynamic responses for a step increase in load demand. The results presented in Fig.12.12 demonstrate that, although the steady-state speed deviation is the same for two units

Now, at X so when U is equal to 0, X dot is equal to X plus gamma p. So, I will write here when U is equal to 0, A X plus gamma p right. Now, your X is equal to a steady state X is equal to X s s the steady state value that means X means all the state variable that means, x 1 s s, x 2 s s, x 3 s s, and x 4 s s right. So, all the study your what to call steady state value of all the state variables.

(Refer Slide Time: 17:22)

$$A = \begin{bmatrix} -\frac{k_p}{T_p} & 0 & 0 & 0 \end{bmatrix}$$

$$B = \Delta P_L$$

$$\dot{X} = AX + Bp$$

$$X = X_{SS}$$

1 stands for transpose.

$$\dot{X} = AX + Bp = 0$$

$$X_{SS} = AX_{SS} + Bp = 0$$

$$\therefore AX_{SS} = -Bp$$

$$X_{SS} = -A^{-1} Bp$$

Fig.12.12 shows the dynamic responses for a step increase in load demand. The results presented in Fig.12.12 demonstrate that, although the steady-state speed deviation is the same for two units

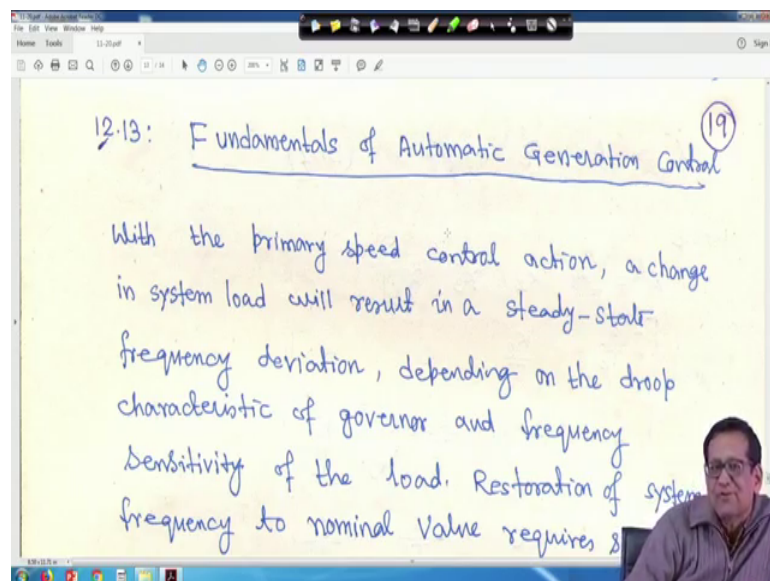

Now, when all these things reach to the steady state, so what will happen to the derivative? Derivative will be 0, when the reach to the steady state all the state variables,

so that means sorry so that means so I can we can write down again that \dot{X} is equal to $A X$ plus γp , but \dot{X} is equal to steady state \dot{X} is equal to $X s$.

So, we can write here, then you substitute $X s$ is equal to $A X$ plus γp right. But, a steady state that all the state variables are derivative will be 0 that mean this one should be is equal to 0 right that means, $A X s$ is equal to minus γp right or multiplied both side by a inverse, then $X s$ will be minus a inverse γp that means, that if A inverse exist for any system, for these all the state all the steady state value of all state variable will be known.

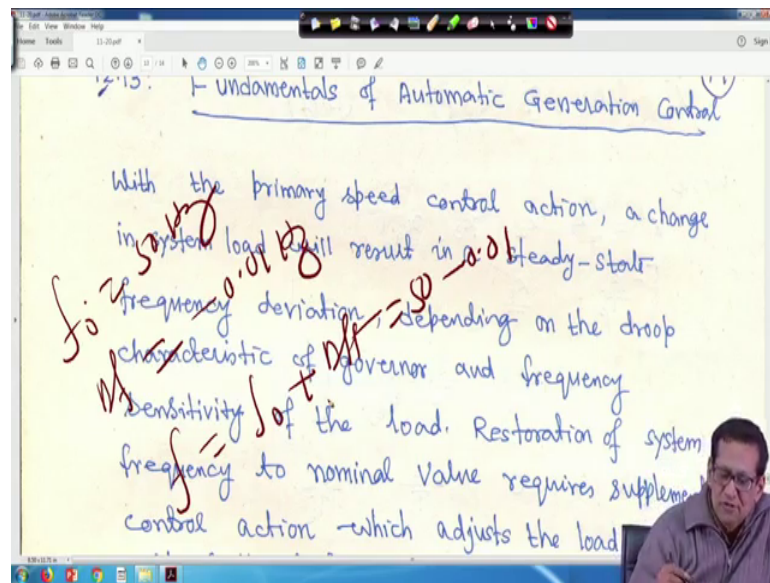

So, simply if you can put it in your Mat lab, and if A inverse exist for the system, then $x_1, x_2, x_3, x_4, \dots$ number of state variable steady state value all will be calculate all it can be computed using this formula $X s$ is equal to minus A inverse γp right. So, this is the way how we can do it right.

(Refer Slide Time: 18:41)

So, next is the fundamentals of automatic generation control.

(Refer Slide Time: 18:45)

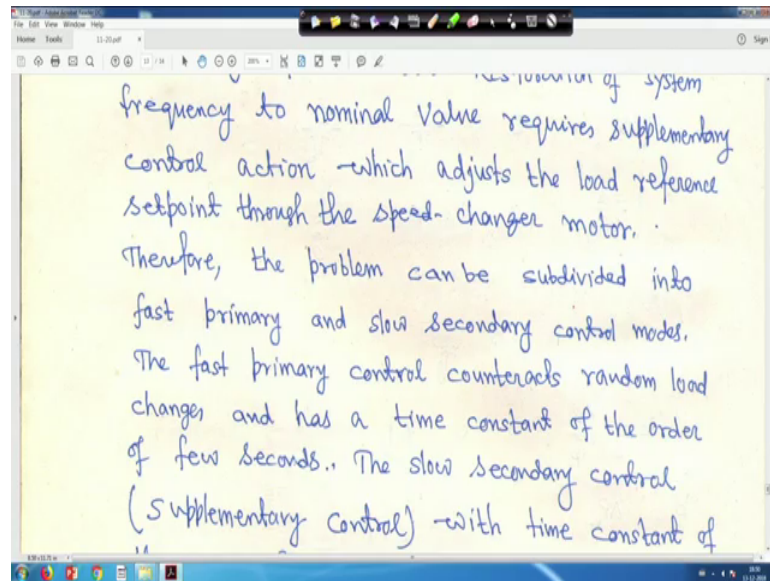

So, with the primary speed control action, actually if primary your when primary controls are later we will see later we will see primary speed control action, a change in system load will result in a steady-state frequency deviation that means, if the primary speed control is there that is governor droop parameter r , so you for a state load disturbance there will be a frequency deviation.

Frequency deviation means, suppose initially it was operating your at f_0 is equal to say 50 hertz right. So, after load disturbance, it is not making the deviation to 0 it is showing some value say some Δf is equal to say we got minus 0.01 hertz right.

So, this is Δf that means, what is the frequency as steady-state. So, frequency as steady-state will be f_0 plus Δf right that is equal to 50 minus 0.01 right. So, this is your what you call that your frequency right, but that means it is not exactly at 50 hertz, but it is less than 50 hertz for increase of the load same will happen for decrease of load of that is frequency will increase right.

So, so depending on the actually depending on that value of that you are what you call the droop characteristic of governor and frequency sensitivity of the load that is the D parameter, it depends on the R , and it depends on the D right.

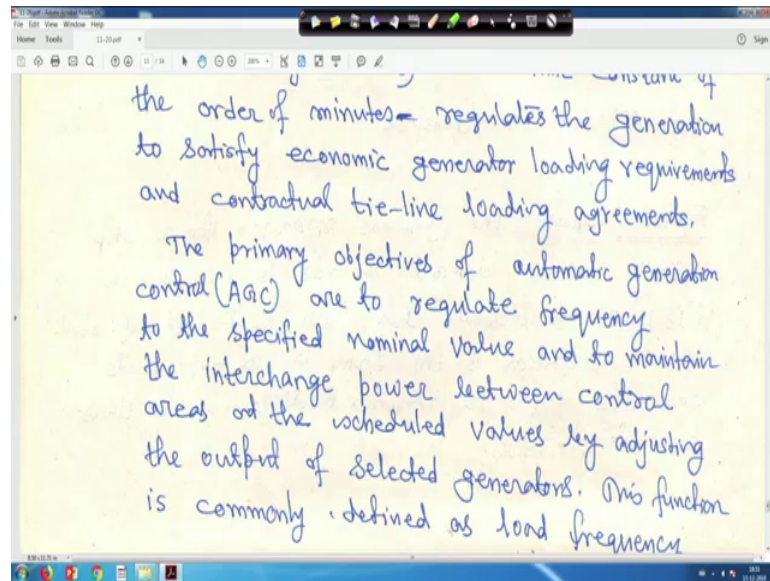

(Refer Slide Time: 20:28)

So, restoration of system frequency to nominal value require supplementary control action right, which just hold on. So, your what you call which adjust the load reference set point through the speed changer motor. Therefore, the problem can be subdivided into fast primary, and slow secondary control modes right.

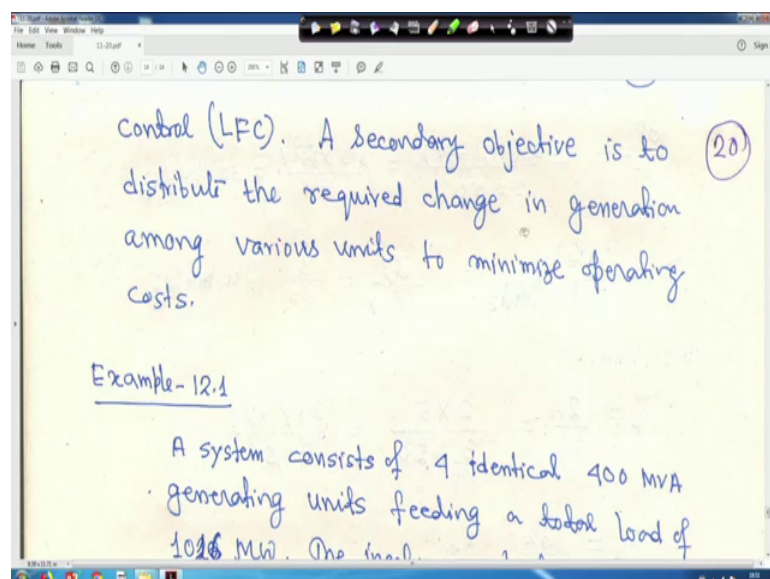

The fast primary control counteracts the random load changes and has a time constant of the order of few second right. So, primary control actually your what you call your it will faster one right. And as a the slow secondary control that is a supplementary control with time constant of the order of minutes actually regulates the your what you call generation to satisfy economic generator loading requirements, contractual tie-line loading agreement that we will see later.

(Refer Slide Time: 21:12)

The primary objective of automatic generation control that is AGC are to regulate frequency to a specified nominal value and to maintain the interchange power between control areas that means, at the schedule value by adjusting the output of selecting selected generator that mean, many power systems are interconnected together right. And they have some schedule interchange power that is that (Refer Time: 21:36) interconnected line, so we call tie-lines right. So, this function is commonly what you call that by adjusting the output of selected generators, this function is commonly defined as load frequency control right.

(Refer Slide Time: 21:48)

A secondary objective is to distribute the required change in generation among various units to minimize operating costs that means, idea is something like this. So, in suppose when economic load dispatch is not there, so automatic generation control is equal to load frequency control we can tell.

But, suppose you have a few control interconnected areas suppose in a particular area there is in increase of load demand say 100 megawatt. And suppose you have three or four different generating units. So, from economic load dispatch, you know that that to minimize the fuel cost that 100 megawatt you have to your optimally you have to distribute among all the generators from the economic load dispatch such that you are fuel cost is minimum.

So, if that your you are what you call that you are apart from you are your this is load frequency control plus economic load dispatch is equal to your automatic generation control. But, if economic load dispatch is not dispatch is not there, then we call it has automatic generation control is equal to load frequency control right. So, much more will come, but before that we will see simple example.

(Refer Slide Time: 23:09)

A system consists of 4 identical 400 MVA generating units feeding a total load of 1016 MW. The inertia constant H of each unit is 5.0 on 400 MVA base. The load changes by 1.5% for a 1% change in frequency. When there is a sudden drop in load by 16 MW.

(a) Obtain the system block diagram with constants H and D expressed 1000

So, a system consists of 4 identical 4 identical 400 MVA generating units feeding a total load of 1016 megawatt this is 1016 megawatt right. The inertia constant H of each unit is 5 on 400 MVA base. So, we have say H means, it is in second right. The load changes by 1.5 percent for a 1 percent change in frequency. This also we have seen how to find out r .

When there is a sudden drop in load by 16 megawatt, this was 1016, this is 16 megawatt just to make that easy calculation right.

(Refer Slide Time: 23:54)

... drop of 16 MW.

(a) Obtain the system block diagram with constants H and D expressed 1600 MVA base

(b) Determine the frequency deviation, assuming that there is no speed-governing action.

Solution

(a) For 4 units on ¹⁶⁰⁰2000 MVA base,

You have to obtain the system block diagram with constant H and D express that 1600 MVA base, because there are 4 units and 400 MVA. So, 4 into 400, it will be 1600 MVA base. And determine the frequency deviation assuming that there is no speed-governing action these two right.

(Refer Slide Time: 24:16)

... frequency deviation, assuming that there is no speed-governing action.

Solution

(a) For 4 units on ¹⁶⁰⁰2000 MVA base,

$$H = 5 \times \left(\frac{400}{1600}\right) \times 4 = 5.0$$

$H_{eq} \times P_{VA_b} = (5 \times 400) \times 4.$

So, first part is for 4 units on 600 MVA base. So, H is equal to actually 5 into 400 divided by 1600 into 4. Actually, here I have tried to I have not completely in write up that basically this is actually H eq into MVA base is equal to 5 into 400 right into your 4 right, so that will give you actually it is 5 right. So, we will go to the next page.

(Refer Slide Time: 24:48)

Assuming $f_0 = 50 \text{ Hz}$

$$\frac{\partial P_L}{\partial f} = \frac{1.5(1016-16)}{1 \times 50} = \frac{1.5 \times 1600}{50} = 30 \text{ MW/Hz}$$

$$D = \left(\frac{\partial P_L}{\partial f}\right) / 1600 = \frac{30}{1600} = \frac{3}{160} \text{ pu MW/Hz}$$

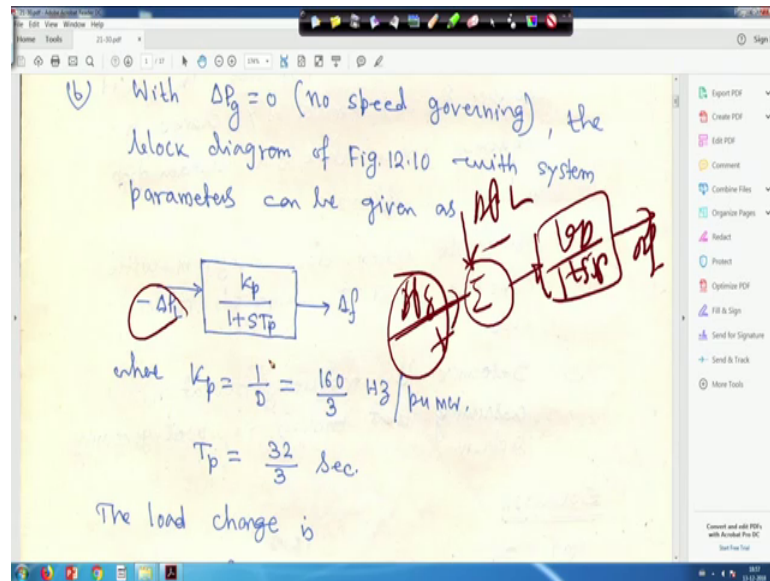

We know

$$T_p = \frac{2H}{D f_0} = \frac{2 \times 5}{\frac{3}{160} \times 50} = \frac{2 \times 5 \times 160}{3 \times 50} = \frac{32}{3} \text{ sec.}$$

So, assuming that f_0 is equal to 50 hertz right. Therefore, ΔP_L upon it is given 1.5 percent change of load changing 1 percent frequency. So, 1.5 percent by 1 percent that is nothing but 1.5 by 1. So, basically this term actually 1.5 percent of this one right. I mean 1.5 percent of because load drop is 16 megawatt divided by 1 percent of 50 hertz right. So, basically percent percent canceled, so that is why written 1.5 by 1.

And this is 1016 minus 16 by 50, so that actually is coming 30 megawatt per hertz right. Therefore, D is equal to ΔP_L upon Δf divided by the 1600 MVA base, because is generator 400, so 1600. So, if you put this one, it will be 3 by 160 per unit megawatt hertz, because megawatt is convert into per unit that is why it represent that writing per unit megawatt per hertz right. We know T_p is equal to $2H$ upon $D f_0$. So, H is known, D computed f_0 known, so T_p is equal to 32 by 3 second right.

(Refer Slide Time: 26:09)

And in the second case that with $\Delta P_g = 0$ that no speed governing action mean ΔP_g is equal to 0. Therefore, block diagram will be simply $\Delta P_g = 0$. So, if you go back to the block diagram, it will be minus P_L , because when you see the when you see the block diagram no speed governing action right, so this is plus ΔP_g , this is minus ΔP_L , and this is K_p upon $1 + sT_p$ right, and this is our Δf .

So, from there one feedback has gone to the governor, but no governing action. So, ΔP_g is equal to 0, therefore this minus ΔP_L , they actually it is given minus ΔP_L K_p upon $1 + 1$ upon K_p upon $1 + sT_p$ Δf . So, K_p is known 1 upon D , T_p is known right.

(Refer Slide Time: 27:05)

The load change is

$$\Delta P_L = 16 \text{ MW} = \frac{16}{1600} = 0.01 \text{ pu MW.}$$

For a step decrease in load by 0.01 pu,
Laplace transform of the change in load is

$$\Delta P_L(s) = \frac{0.01}{s}$$

From the block diagram

$$\Delta f(s) = \left(\frac{-0.01}{s} \right) (K_p)$$

Their load change is your delta P L is 16 megawatt. So, base is 1600, so 0.01 per unit megawatt. And it is a step decrease, so delta P L will be 0.01 upon S because of step input right.

(Refer Slide Time: 27:18)

For a step decrease in load by 0.01 pu,
Laplace transform of the change in load is

$$\Delta P_L(s) = \frac{0.01}{s}$$

From the block diagram

$$\Delta f(s) = \left(\frac{-0.01}{s} \right) \left(\frac{K_p}{1+sT_p} \right)$$

And the find the from the block diagram this one will be this one, and what you can what you can do is you take the inverse Laplace transform.

(Refer Slide Time: 27:26)

The image shows a handwritten derivation on a digital whiteboard. The equations are as follows:

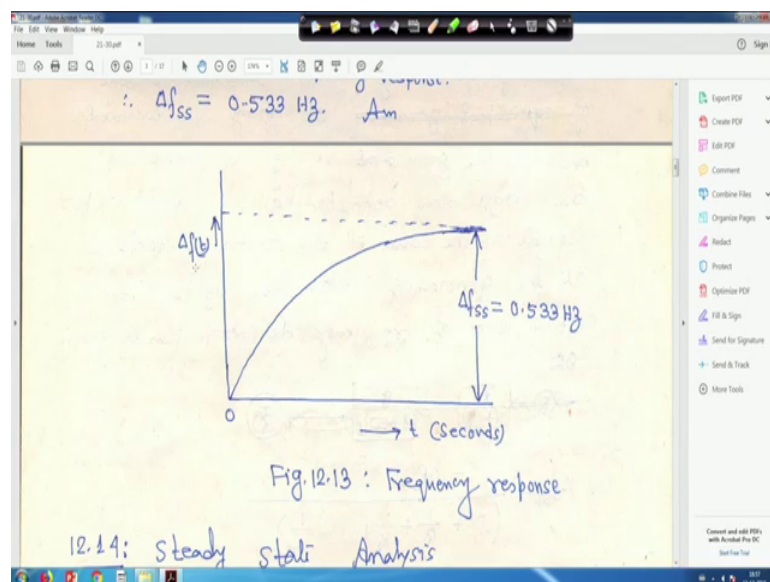

$$\therefore \Delta f(t) = -0.01 K_p e^{-t/T_p} + 0.01 K_p$$
$$\therefore \Delta f(t) = 0.01 \times \frac{160}{3} - 0.01 \times \frac{160}{3} e^{-t/(32/3)}$$
$$\therefore \Delta f(t) = \frac{1.6}{3} \left(1 - e^{-3t/32} \right) \text{ Am}$$

Fig.12.13 shows the frequency response.

$$\therefore \Delta f_{ss} = 0.533 \text{ Hz. Am}$$

If you do so, it will become minus 0.01 K p e to the power minus t upon T p plus 0.01 K p right or delta f t is equal to put all the data, it will be 1.6 upon 3 1 minus e to the power of minus 3 t upon 32, this is the answer.

(Refer Slide Time: 27:45)

And t tends to infinity, so Δf_{ss} will become 0.533 this is the steady-state error right. And this is your what you call Δf t verses Δf_{ss} this is the plot right, so this is the steady-state value right. So, load increase or load decrease whatever it is that you can do it easily this is special case, this is a special case right.

So, thank you very much, we will be back again.
