Lecture - 53
State estimation in power system (Contd.)

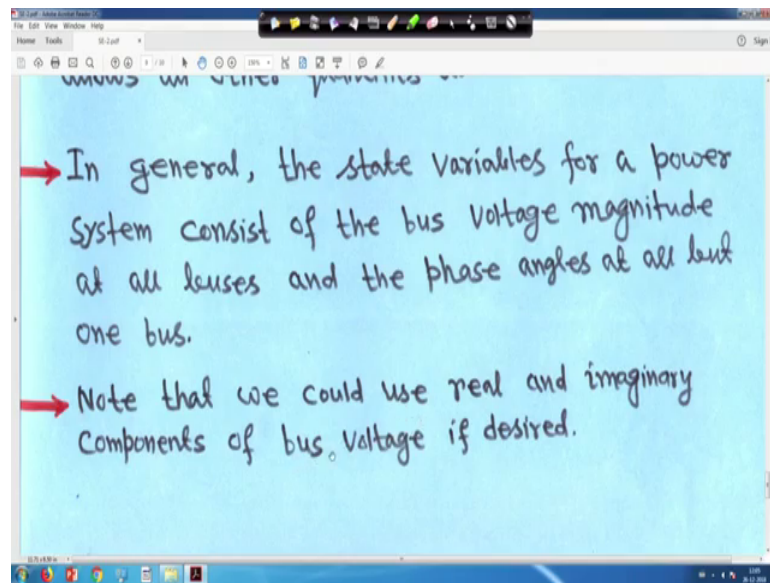

So we are, we are back again, so in the previous example we have seen that, the delta 1 and delta 2 the state variables for the three-bus system since knowing them allows all other quantities to be calculated right.

(Refer Slide Time: 00:31)

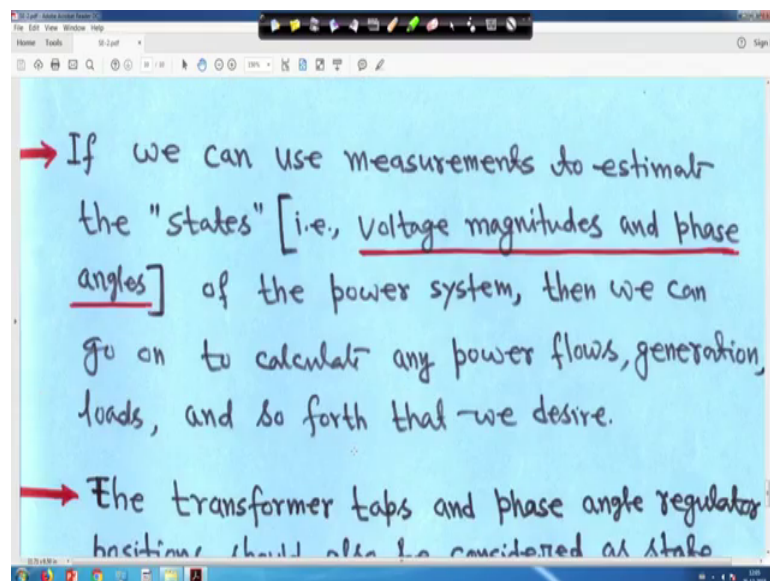

So, in general the state variables for a power system consists of the bus voltage magnitude at all buses and the phase angle at all but one bus that is slack bus right.

(Refer Slide Time: 00:49)

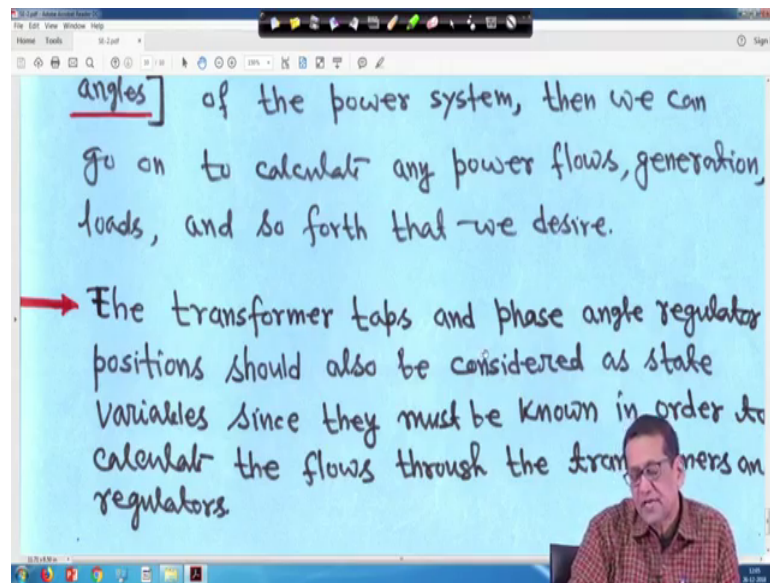

Note that we could use real and imaginary components of bus voltage if desired.

(Refer Slide Time: 00:53)

So, this all these things we have seen. If we, but just starting from the end of the previous lecture. If we can use measurements to estimate the "states" that is, voltage magnitude and phase angle in this case of the power system, then we can go on to calculate any power flows, generation loads, and so forth right; that we desire.

(Refer Slide Time: 01:15)

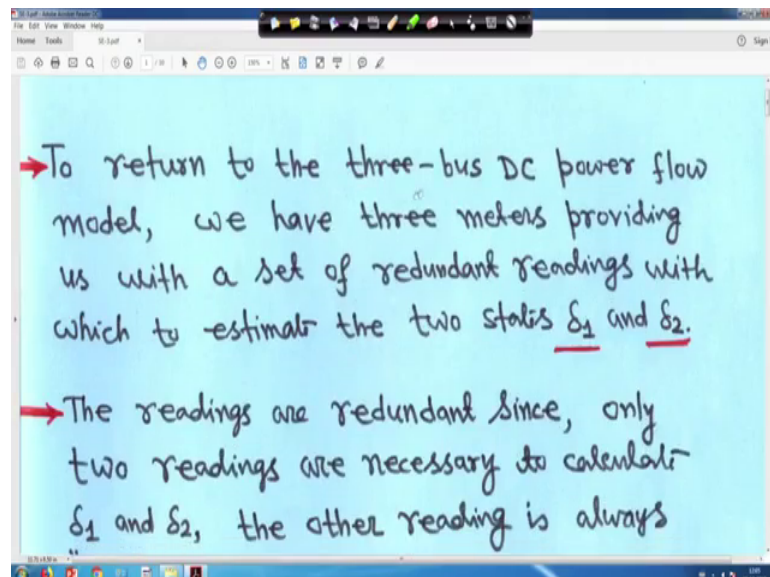

angles] of the power system, then we can go on to calculate any power flows, generation, loads, and so forth that we desire.

→ The transformer taps and phase angle regulator positions should also be considered as state variables since they must be known in order to calculate the flows through the transformers and regulators.

The transformer taps and phase angle regulator positions should also be considered as state variable since they must be known in order to calculate the flows through the transformers and regulators right. So, that is what we have seen. Now just hold on. Let me increase the size.

(Refer Slide Time: 01:43)

→ To return to the three-bus DC power flow model, we have three meters providing us with a set of redundant readings with which to estimate the two states δ_1 and δ_2 .

→ The readings are redundant since, only two readings are necessary to calculate δ_1 and δ_2 , the other reading is always

So, now to return to the three-bus DC power flow model, we have three meters providing us with a set of redundant readings with which to estimate the two states that is delta 1 and delta 2. There are two states, but we had three measurements right.

(Refer Slide Time: 01:59)

us with a set of redundant readings with which to estimate the two states δ_1 and δ_2 .

→ The readings are redundant since, only two readings are necessary to calculate δ_1 and δ_2 , the other reading is always "extra". However, the "extra" reading does carry useful information and ought not to be discarded summarily.

So, the readings are redundant since only two readings are necessary to calculate δ_1 and δ_2 . The other reading is always "extra". However, the "extra" reading does carry useful information and what not to be discarded summarily right.

(Refer Slide Time: 02:17)

MAXIMUM ~~LIKELIHOOD~~ LIKELIHOOD WEIGHTED LEAST-SQUARES ESTIMATION.

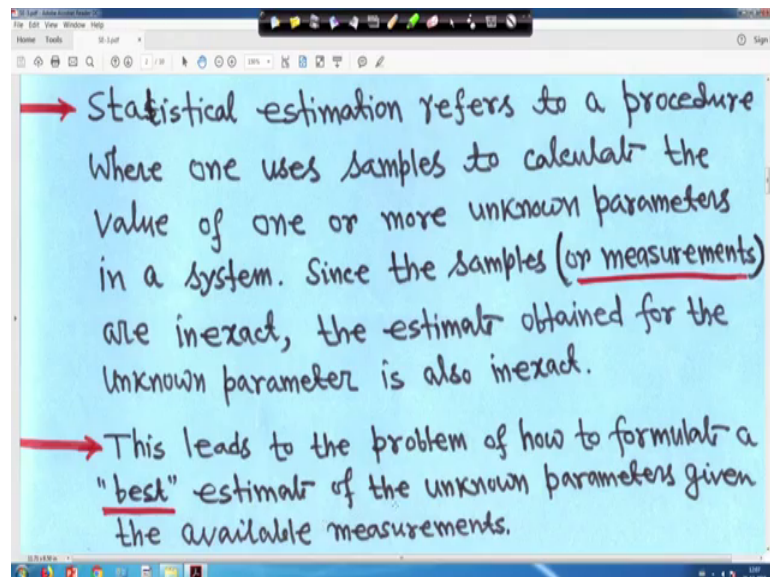

→ Statistical estimation refers to a procedure where one uses samples to calculate the value of one or more unknown parameters in a system. Since the samples (or measurements)

So, that is why if it is so, then that then we will go for a new concept right. That how we can accommodate all this thing. So, for state estimation that we will do static state estimation, but we will see three types of phases way of c. Mainly one is that when number of state variables are greater than your number of measurement. That is $n > m$

greater than $n \times m$. Another case number of state variable is equal to number of measurement that is $n \times s$ is equal to $n \times m$. Another is number of state variables where $n \times s$ less than $n \times m$ that is number of state variables less than number of measurements right.

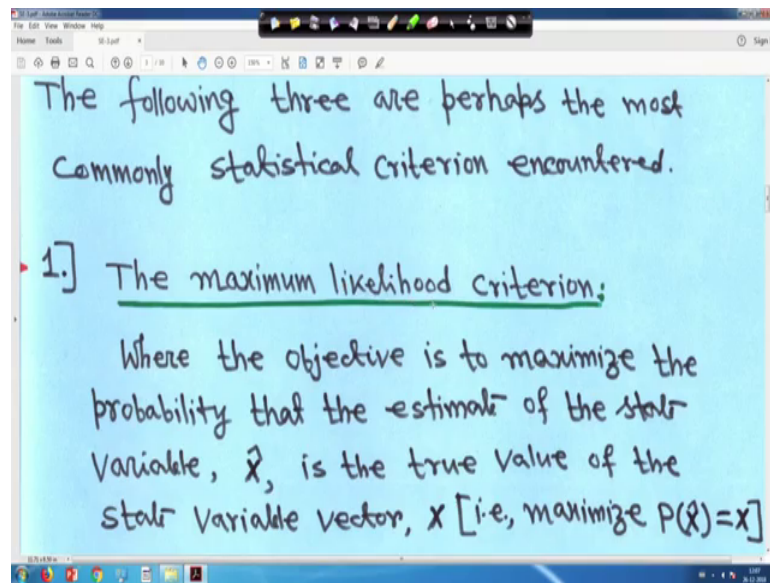

So, Maximum likelihood weighted least-square estimation. Likelihood means probability right. So, statistical estimation refers to a procedure which are you which one use a use a samples to calculate the value of one or more unknown parameter in a system. Since the samples that is measurements right. I have underlined this one are inexact; that is not true value not correct value right.

(Refer Slide Time: 03:13)

The estimate obtained for the unknown parameter is also in a inexact, but we have to see that how close it is to the true values right. This actually leads to the problem of how to formulate a "best" estimate of the unknown parameters given the available measurement right.

(Refer Slide Time: 03:37)

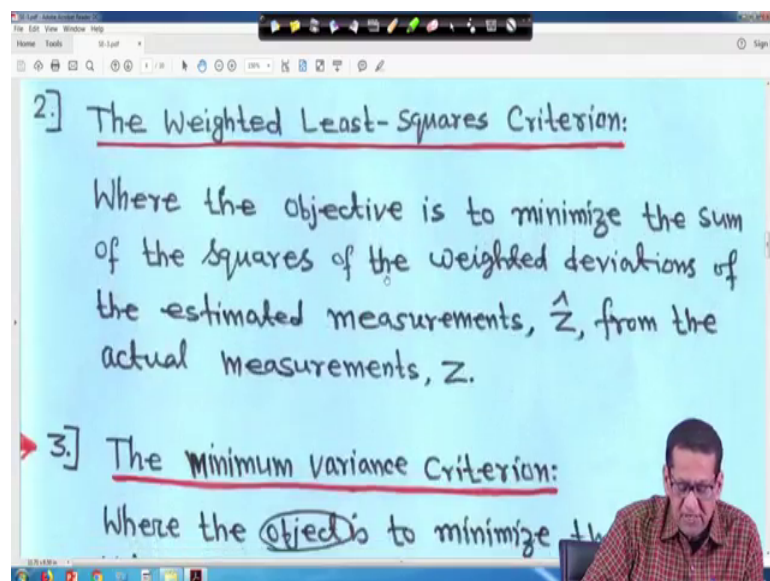

The following three are perhaps the most commonly statistical criterion encountered.

1.] The maximum likelihood criterion:
Where the objective is to maximize the probability that the estimate of the state variable, \hat{x} , is the true value of the state variable vector, x [i.e, maximize $P(\hat{x}=x)$ ']

The following three are perhaps the most commonly statistical criteria encountered. Number 1 is: The maximum likelihood criteria. Here actually that is maximum likelihood means it is probability. Then you are maximize the probability right. Where the objective is that to maximize the probability that the estimate of the state variable X cap right is the true value of the state variable vector X . That is maximize $P X$ cap is equal to X you have to maximize the probability this is maximum likelihood criteria right.

(Refer Slide Time: 04:13)

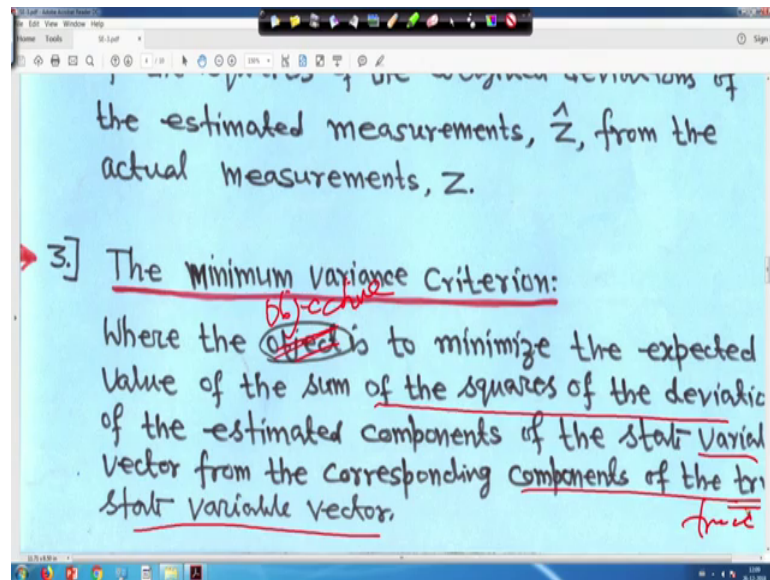

2.] The Weighted Least-Squares Criterion:
Where the objective is to minimize the sum of the squares of the weighted deviations of the estimated measurements, \hat{z} , from the actual measurements, z .

3.] The Minimum Variance Criterion:
Where the object is to minimize the

Next one is, that you are the weighted least-square criteria; here where the objective is to minimise the sum of the squares of the weighted deviations of the estimated measurements that is \hat{z} from the actual measurement that is z . sorry. So, this is weighted least-square criteria.

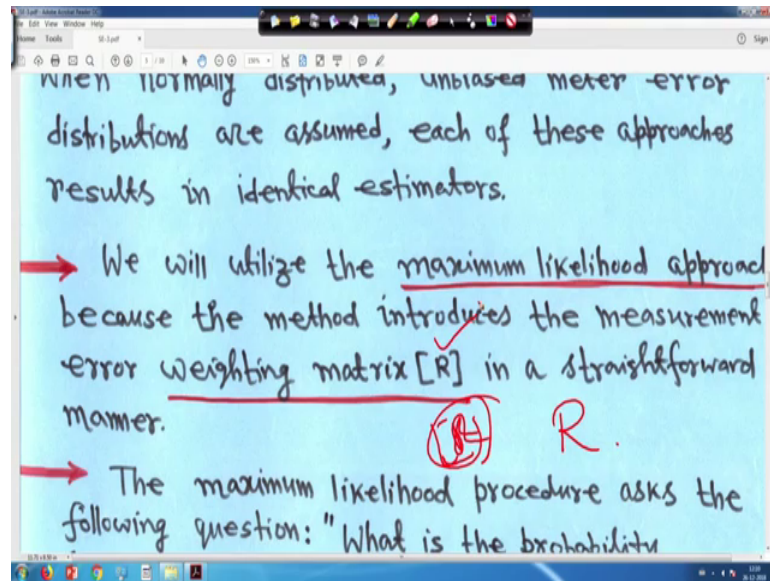

(Refer Slide Time: 04:35)

Third one is the minimum variance criteria right. In this case that the object is actually objective right, by it is written object it is objective. Where the objective is to minimise the expected value of the sum of the squares of the deviation of the estimated components of the state variable vector from the corresponding components of a true state variable vector right.

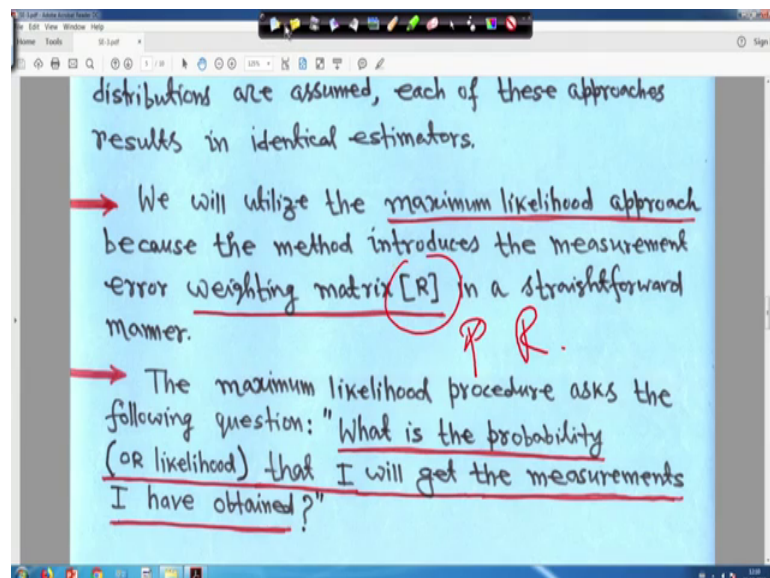

So, these are the actually it was your what you call it is variable and it is actually true right; true state variable vector. This is little bit cut but a just I am telling this one, this is actually true value right. So, that is actually this three different criterias you have and we have to follow certain things right; rhe certain mathematical procedure.

(Refer Slide Time: 05:23)

Now, when normally distributed, that is unbiased meter error distributions are assumed that each of these approaches results in identical estimators right. We will utilise the maximum likelihood approach because the method introduces the measurement error weighting metrics R . Sometimes what I will do, when I am writing it is actually R it is R matrix instead of that some later values R only; so understandable right. Just put in bracket that is the source that your matrix right. So, it is in a straight forward manner.

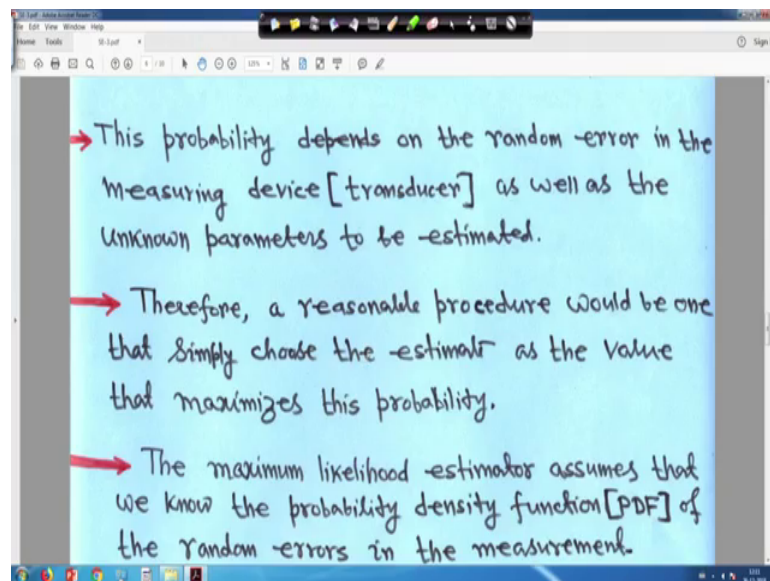

(Refer Slide Time: 06:01)

Student: Sir, (Refer Time: 05:59).

We will utilise the maximum likelihood approach because the method introduces the measurement error waiting matrix R right in a straight forward manner. So, sometimes I will simply right that simply right r right. So, but here I am made it in bracket R to show that it is a matrix. So, the maximum likelihood procedure ask the following questions. That is what is the probability in bracket I have written or likelihood that I will get the measurement I have obtained right; so this is that criteria the maximum likely proceed your likelihood procedure right.

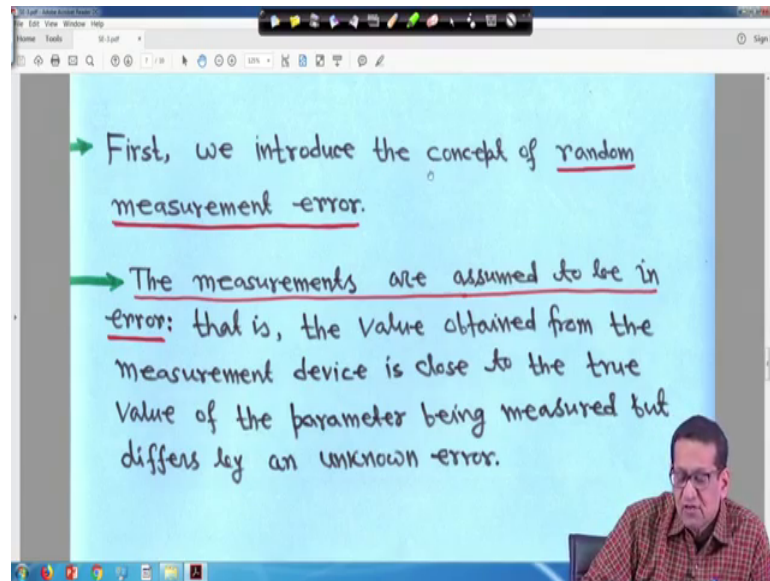

(Refer Slide Time: 06:41)

So, this probability actually depends on the random error in the measuring device that is transducer as well as the unknown parameters to be estimated. Therefore, a reasonable procedure would be one that simply choose the estimate as the value of maximizing, maximizes this that provide that maximizes the probability right.

The maximum likelihood estimator assumes that we know the probability density function that is equal PDF right, of the random errors in the measurement.

(Refer Slide Time: 07:13)

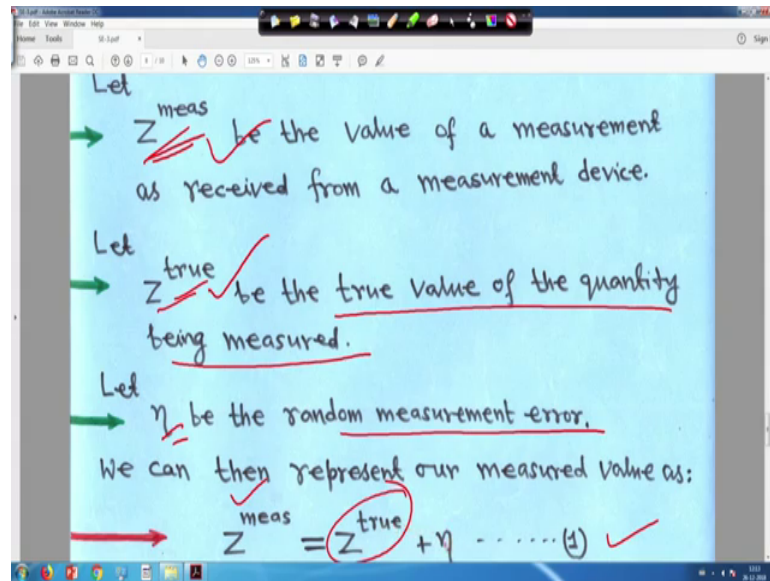

Now, first let us introduce the concept of random measurement error. The measurement errors are assumed to be in error, we are assuming that every measurement has some errors. For example, when you are doing your experiment in the laboratory you have ammeter, voltmeter, wattmeter and other type of meters when you take the reading you will see that as soon as you connect and try to take the reading you will find the point are actually oscillating around some point. When that pointer is settling to some point you are taking the reading, basically you are taking the mean reading right. Because it is or two reading is there, but both side you will find a point that is oscillating.

So, ultimately when it is settle down your taking the reading basically that is mean reading right. And in the ammeter or voltmeter just check it will be written somewhere are so, instruments that accuracy. Suppose if it is written that accuracy plus minus 3 percent right. That is if it is written like this, so that is actually 3 sigma right is equal to plus minus 3 percent the standard deviation right.

So, that the value obtained from the measurement device is close to the true value of the parameter being measured, but differs by an unknown error. Because it we are measuring, but measurement is not your exact right; it is in exact inexact. So, some error will be there.

(Refer Slide Time: 08:35)

So, now let us let us make it like this, that you assume that Z measure right; let Z measure that is your this one be the value of a measurement or as received from a measurement device. It may be it may be volt, it may be current, ampere, it may be megawatt, it may be mega bar right like this.

So, that the hand and let Z true, this is Z true be the true value of the quantity being measured. This is the measured value and this is the true value right. Now let zeta be the random measurement error right. Therefore, we can right that Z measure is equal to Z true plus zeta; this is equation 1. So, this is our true value, but we are assuming that zeta be the random measurement error. So, Z measure actually g g Z true plus zeta right.

(Refer Slide Time: 09:35)

The slide contains the following text:

- The random number, η , serves to model the uncertainty in the measurements.
- If the measurement error is unbiased, the probability density function of η is usually chosen as a normal distribution with zero mean.
- Note that other measurement probability density functions will also work in the maximum likelihood method as well.

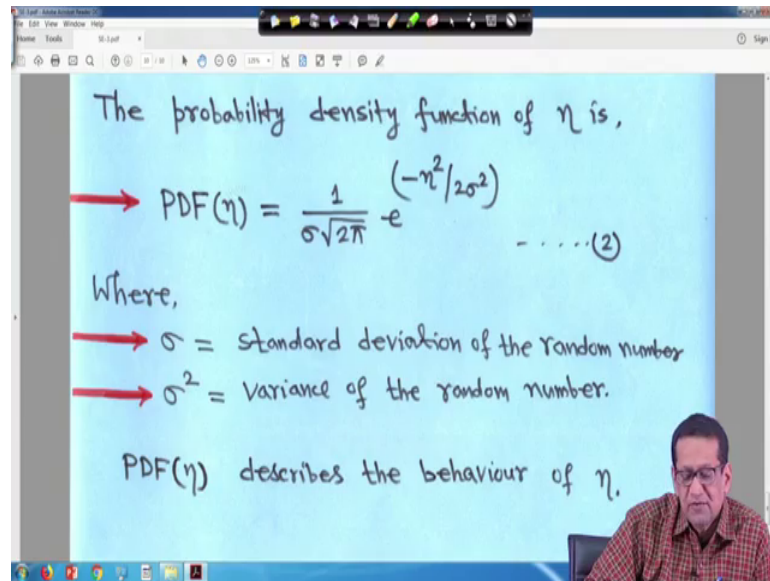

Handwritten notes on the slide include a circled η with an arrow pointing to the word "mean" in the second bullet point, and the equation $Z = Z + \eta$ written in red.

So, that way that way we will define that, than now the random number zeta actually subs to the model uncertainty in the measurement right. So, this is actually random number it subs to a model the uncertainty in the measurement.

If the measurement error is unbiased right the probability density function of zeta is usually chosen as a normal distribution with zero mean. So, that means, if the measurement error is unbiased the probability density function of zeta is usually chosen as normal distribution with zero mean I mean would not mean is zero. Therefore, if it is happens, so note that the other measurement probability density function will also work in the maximum likelihood method as well.

So, it mean value of I mean we are writing Z measure in the previous equation 1, Z true plus zeta right. If the mean value of the your what you call, that a your random number that zeta is 0. Therefore, mean value of Z a measure will be is equal to the mean value of Z I mean this thing Z true right.

(Refer Slide Time: 10:47)

The probability density function of η is,

$$\text{PDF}(\eta) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\eta^2/2\sigma^2} \dots\dots(2)$$

Where,

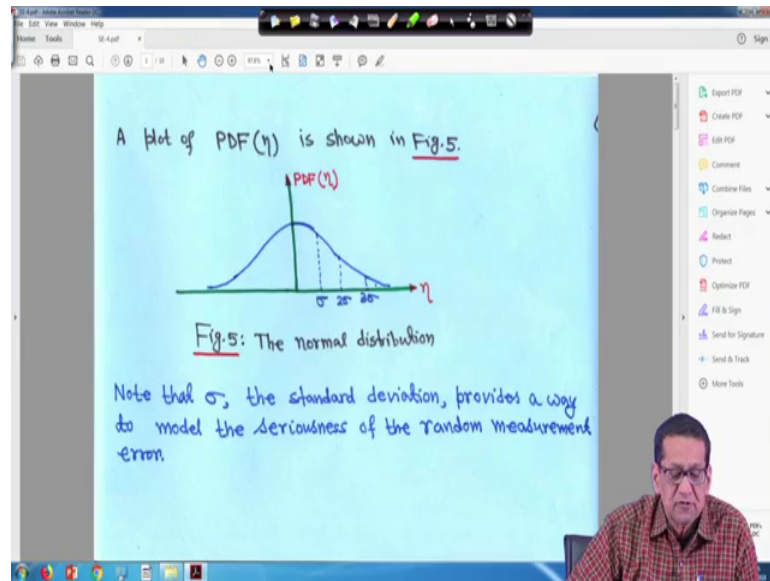

- σ = standard deviation of the random number
- σ^2 = variance of the random number.

PDF(η) describes the behaviour of η .

So, that is why the probability density function of zeta can be written as is a normal distribution your probability for probability expression that is PDF that is probability density function zeta is equal to one upon sigma root over 2 pi into e to the power minus your zeta square upon 2 sigma square; this is equation 2. This you know this expression from your mathematics probability chapter. You know this, this expression is a standard expression for normal distribution.

Where sigma is equal to you know the standard deviation of the random number and sigma square is the variance of the random number right. Now PDF zeta actually describes the behaviour of the behaviour of zeta right. So, this is a stand we define this one as a probability density function zeta is equal to this is a normal distribution sorry. So, now we will go to the next page just hold on.

(Refer Slide Time: 11:39)

So, the plot, just hold on; so the plan your the plot or probability density function that is PDF zeta, versus zeta is given this is sigma, this is 2 sigma, this is 3 sigma and it is actually your what you call the normal distribution. The normal distribution, the PDF zeta versus zeta curve right. And note that sigma the standard deviation provides a way to model the seriousness of the random measurement error right.

(Refer Slide Time: 12:11)

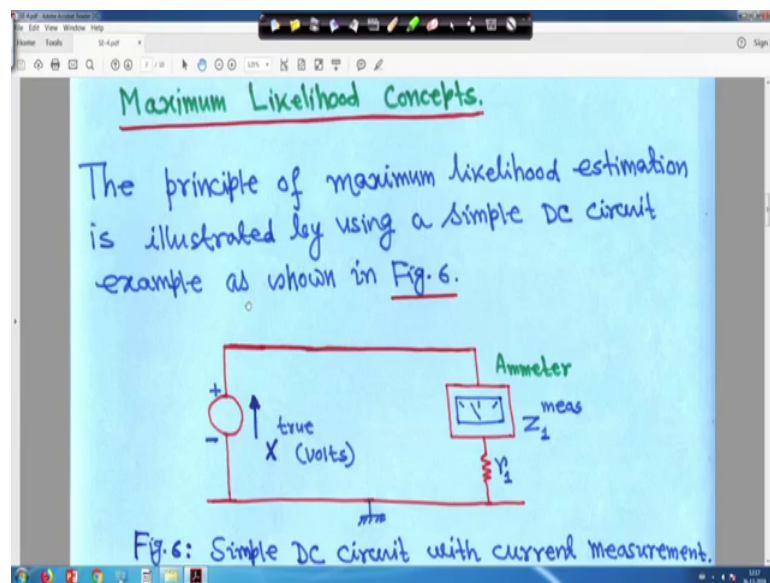

→ If σ is large, the measurement is relatively inaccurate (i.e., a poor-quality measurement device), whereas a small value of σ denotes a small error spread (i.e., a higher-quality measurement device).

→ The normal distribution is commonly used for modeling measurement errors since it is the distribution that will result when many factors contribute to the overall error.

So, if sigma is large, the measurement is relatively inaccurate that is a poor quality measurement device. Because you are standard division is large; that means, the

measurement device is not giving you the best answer right. Be best measurement. So, it is a poor quality measurement device. Where as a small value of sigma, when sigma is very low that is standard deviation is very low denotes a small error spread that is a higher quality of measurement, higher quality measurement device right. Now the normal distribution actually is commonly used for modelling measurement errors since it is the distribution that will result when many factors contribute to the overall error right.

(Refer Slide Time: 12:53)

So, for example, for example, say you consider a maximum likelihood concept; that how things are. For example, you consider a simple DC circuit right. It has a voltmeter, it is given like this X true is actually it is a volt, and there is an ammeter also and it is a measuring the current we get Z 1 measurement and r 1 is the resistance of the circuit right. So, the principles of maximum likelihood estimation is illustrated by using a simple DC circuit example and so as shown in figure 6 right. So, this is the voltage it is the true value we have to estimate this true value of the voltage another taken a simple circuit phase.

So, it is a voltage source and an ammeter is there when resistance is there in r that is r 1 right. And this is Z 1 measure; actually if this is Z 1 measure means it is the ammeter, amp ampere. So, Z 1 measure means it will be X true upon x upon r 1 in general right. Because X is the volt and Z is the current ampere right.

(Refer Slide Time: 13:53)

→ In this example, we wish to estimate the value of the voltage source x^{true} , using an ammeter with an error having a known standard deviation.

→ The ammeter gives a reading of Z_1^{meas} , which is equal to the sum of Z_1^{true} [the true current flowing in Fig. 6] and η_1 [the error present in the Ammeter]

So, now in this example we used to estimate the value of the voltage source x^{true} using an ammeter with a error having a known standard deviation. We know the ammeter and we know the known standard deviation right. Now ammeter gives a reading of Z_1^{meas} , this is actually giving editing that give Z_1^{meas} right. So, which is equal to the sum of the Z_1^{true} ; that is the true current flowing in figure 6; there is a true current flowing in this figure 6 right. And η_1 the error present in Ammeter. This expression we have seen the Z^{meas} is equal to Z^{true} plus η . So, here it will be Z_1^{meas} will be is equal to Z_1^{true} plus η_1 .

(Refer Slide Time: 14:39)

Then we can write, $\eta_1 = Z_1^{\text{meas}} - Z_1^{\text{true}}$

→ $Z_1^{\text{meas}} = Z_1^{\text{true}} + \eta_1 \dots (3)$

→ Since the mean value of η_1 is zero, we then know that the mean value of Z_1^{meas} is equal to Z_1^{true} .

→ This allows us to write a probability density function $f(x)_{\text{meas}}$

So, here now we can write that, Z_1 measure is equal to Z_1 true plus ζ_1 this is equation 3. Therefore, ζ_1 is equal to your Z_1 measure minus Z_1 true right. So, because that ζ_1 expression we will use since the mean value of ζ_1 is zero I told you with a no that mean value of Z_1 me; that means, there is equal to Z_1 true right because this ζ_1 mean value is zero. So, mean value of Z_1 measure is equal to Z_1 true Z true right.

(Refer Slide Time: 15:23)

PDF(Z_1^{meas}) = $\frac{1}{\sigma_1 \sqrt{2\pi}} e^{-\frac{(Z_1^{meas} - Z_1^{true})^2}{2\sigma_1^2}}$... (4)

Where

σ_1 = standard deviation for the random error η_1 .

If we assume that the value of the resistance, r_1 , in Fig-6 is known, then we can write.

These actually allow us to write a probability density function for Z_1 measure as. So, in this case, we can write then PDF Z_1 measure is equal to $\frac{1}{\sigma_1 \sqrt{2\pi}}$ the standard deviation is σ_1 to 2π right. It into e to the power actually it was minus your ζ_1 square upon $2\sigma_1$ square. But ζ_1 is equal to Z_1 measure minus Z_1 true. So, that is why it is minus Z_1 measure minus Z_1 true whole square upon $2\sigma_1$ square. This is equation four this is the probability density function for Z_1 measure right. Where σ_1 is equal to standard deviation for the random error that is ζ_1 .

If we assume that the value of the resistance, r_1 , in figure 6 is known, then we can write right. We are assuming that that in the figure 6 the resistance of the DC circuit r_1 is known then we can write.

(Refer Slide Time: 16:11)

The image shows a video lecture interface. At the top, there is a window title bar for 'UAF - Alexander Hernandez' and a menu bar with 'File', 'Edit', 'View', 'Window', and 'Help'. Below the menu bar is a toolbar with various icons. The main content is a whiteboard with handwritten text in blue ink. The equation for the PDF of z_1^{meas} is written as:

$$\text{PDF}(z_1^{\text{meas}}) = \frac{1}{\sigma_1 \sqrt{2\pi}} \exp\left[-\frac{(z_1^{\text{meas}} - \frac{x}{r_1})^2}{2\sigma_1^2}\right]$$

Below the equation, it is labeled as equation (5). The text below the equation reads: "Coming back to our definition of a maximum likelihood estimator, we now wish to find an estimate of x [called x^{est}] that maximizes the probability that the observed measurement z_1^{meas} would occur." In the bottom right corner of the whiteboard, there is a small inset video of a man with glasses and a red shirt, who is the lecturer.

That your this term that Z_1 , Z true that is your Z true it will be x upon r , because Z is the ampere your ammeter reading say, it is ampere and x is the volt, so volt by your resistance r so ampere. So, Z actually, Z true is actually x upon r , this term is replaced by x upon r . That means, by PDF Z_1 measure is equal to 1 upon σ_1 root over 2π e to the power minus bracket Z_1 measure minus x upon r whole square upon $2\sigma_1^2$ square this is equation 5 right.

Now, coming back to our definition of a maximum likelihood estimator, we now wish to find an estimate of x called x is equal to x^{est} that is x estimator right. That maximizes the probability there that the observe measurement Z_1 measure would occur right. So, this is for a just a simple circuit we have taken and this is the probability density function for Z_1 measure.

(Refer Slide Time: 17:15)

Since we have the probability density function of Z_1^{meas} , we can write

$$\rightarrow \text{prob}(Z_1^{\text{meas}}) = \int_{Z_1^{\text{meas}}}^{Z_1^{\text{meas}} + dZ_1^{\text{meas}}} \text{PDF}(Z_1^{\text{meas}}) dZ_1^{\text{meas}}$$

as $dZ_1^{\text{meas}} \rightarrow 0$

$$= \text{PDF}(Z_1^{\text{meas}}) dZ_1^{\text{meas}} \dots (6)$$

Since we have the probability density function of Z_1 measure, we can write like this the probability of Z_1 measure is equal to, it is actually Z_1 measure to Z_1 measure plus dZ_1 measure right. That is integration this is a limit.

Then PDF Z_1 measure into dZ_1 measure right. As dZ_1 measure actually tends to 0, you can write PDF Z_1 measure into dZ_1 measure right. Because dZ_1 measure is a very small thickness very small one, I suggest you go to the graph and just find out how things are happening, but from your probability studies you have studied this right. So, since we have the probability density function like this, then this one actually can be written as PDF Z_1 measure into dZ_1 measure this is equation 6 right.

(Refer Slide Time: 18:11)

The maximum likelihood procedure then requires that we maximize the value of $\text{prob}(Z_1^{\text{meas}})$, which is a function of x . That is,

$\rightarrow \therefore \text{Maximize prob}(Z_1^{\text{meas}}) = \text{Maximize PDF}(Z_1^{\text{meas}}) dx$... (7)

One convenient transformation that can be at this point is to maximize the natural log of the likelihood function.

So, the next the maximum likelihood procedure then requires that we will maximize the value of probability Z 1 measure.

(Refer Slide Time: 18:17)

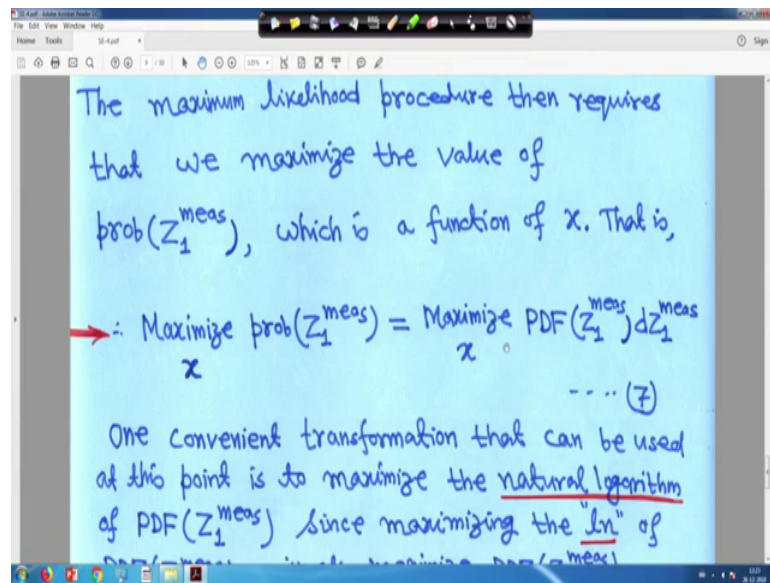

Since we have the probability density function of Z_1^{meas} , we can write

$\rightarrow \text{prob}(Z_1^{\text{meas}}) = \int_{Z_1^{\text{meas}}}^{Z_1^{\text{meas}} + dZ_1^{\text{meas}}} \text{PDF}(Z_1^{\text{meas}}) dZ_1^{\text{meas}}$ as $dZ_1^{\text{meas}} \rightarrow 0$

$= \text{PDF}(Z_1^{\text{meas}}) dZ_1^{\text{meas}}$... (6)

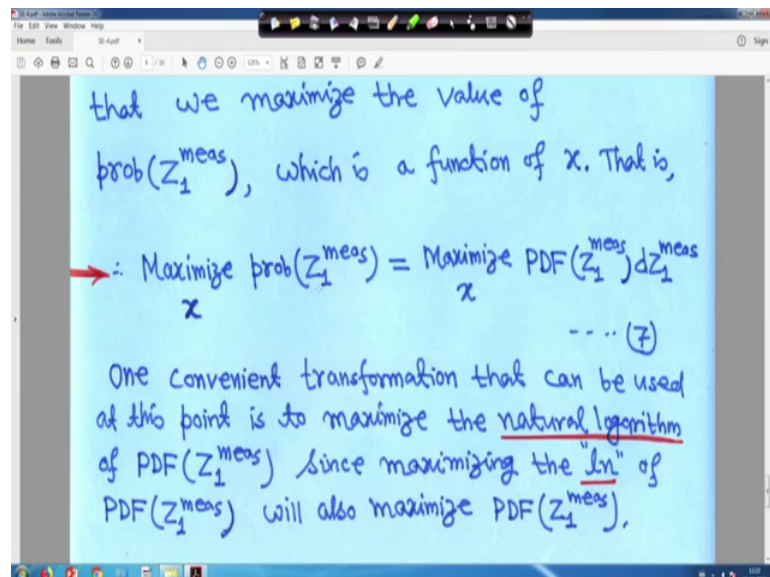

We have to actually maximize this one, that probability of Z 1 measure we have to maximize this one right. So, nothing but you have to maximize this one PDF Z 1 measure right.

(Refer Slide Time: 18:23)

So, therefore, which is function of x ; so the maximum likelihood procedure then requires that we maximize the value of probability of Z_1 measure, which is actually is a function of x . That is maximize probability of Z_1 measure and it is function of x is equal to maximize your PDF Z_1 measure into $d Z_1$ measure right. And that is your equation 7.

(Refer Slide Time: 18:55)

Now, how to maximize this? Things are very simple. One convenient transformation that can be use at this point is to maximize the natural logarithm of PDF Z_1 measure. Since maximize the your "ln" that is natural logarithm of PDF Z_1 measure will also maximize

PDF of your Z_1 your what you call measure right. So, when you are try to maximize PDF of Z_1 measure if you take is natural log logarithm it will be the same thing.

(Refer Slide Time: 19:23)

Then we wish to find

→ Maximize_x $\ln[\text{PDF}(Z_1^{\text{meas}})]$

op → Maximize_x $\left[-\ln(\sigma_1\sqrt{2\pi}) - \frac{(Z_1^{\text{meas}} - \frac{x}{r_1})^2}{2\sigma_1^2} \right]$

Since the first term is constant, it can be ignored. We can maximize the function

If it is so then we wish to maximize, wish to find out maximize the natural logarithm of PDF Z_1 measure right, for which we can find out the true value.

So, if you do so, if you do so, you take natural log of this equation, of this equation. This equation you take the natural log right. Then what will happen? That it will be minus $\ln(\sigma_1 \sqrt{2\pi})$ then, minus you are what you call $\frac{1}{2} \ln(Z_1^{\text{meas}} - \frac{x}{r_1})^2$ divided by your what you call divided by $2\sigma_1^2$ right. So, here also we have written that one, that you are maximize; that means, maximizing PDF function Z_1 is same thing that maximizing natural log of PDF of Z_1 measure. So, this will be maximize minus $\ln(\sigma_1 \sqrt{2\pi})$ and this is minus your $Z_1^{\text{meas}} - \frac{x}{r_1}$ whole square upon $2\sigma_1^2$, because we are taken the natural log right.

(Refer Slide Time: 20:31)

→ Maximize $x \ln[\text{PDF}(z_1^{\text{meas}})]$

op → Maximize $x \left[-\ln(\sigma_1 \sqrt{2\pi}) - \frac{(z_1^{\text{meas}} - \frac{x}{\mu})^2}{2\sigma_1^2} \right]$.

Since the first term is constant, it can be ignored. We can maximize the function in brackets by minimizing the second term since it has a negative coefficient.

Now, since the first term is constant, because this is a constant; if first term is a constant right. It is a first time is a constant. So, generally maximize means we have to take $\frac{d}{dx}$, but anyway of 0, $\frac{d}{dx}$ of that term is first term is your what you call, it is a constant and second term a minus sign is there before this before this term a minus sign is there, that mean maximize this term means minimization of this term actually we will maximize this term. Because first term is a constant right and a minus sign is there before that. Therefore, we can maximize the function in brackets by minimising the second term since it has a negative coefficient this is negative right.

(Refer Slide Time: 21:23)

That is,

→ Maximize $x \left[-\ln(\sigma_1 \sqrt{2\pi}) - \frac{(z_1^{\text{meas}} - \frac{x}{\mu})^2}{2\sigma_1^2} \right]$

is the same as,

→ Minimize $x \left[\frac{(z_1^{\text{meas}} - \frac{x}{\mu})^2}{2\sigma_1^2} \right] \dots\dots (8)$.

Therefore, just hold on. That is your maximize your just hold on let me increase its size. That is your maximize x minus $1/n \sigma_1 \sqrt{2\pi}$ minus Z_1 measure minus x upon r_1 your what you call whole square upon $2\sigma_1$ whole square. It is simply actually minimise x that is Z_1 measure minus x upon r_1 whole square divided by $2\sigma_1$ square this is equation 8. So, minimise x means you will take d/dx of this one is equal to 0 right.

(Refer Slide Time: 21:57)

The value of x that minimizes the right-hand term is found by simply taking the first derivative and setting the result to zero.

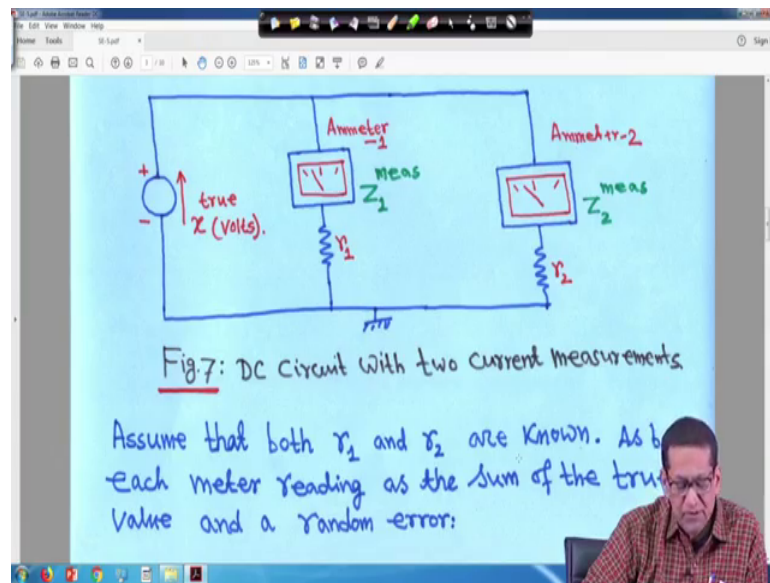

$$\therefore \frac{d}{dx} \left[\frac{(Z_1^{\text{meas}} - \frac{x}{r_1})^2}{2\sigma_1^2} \right] = \frac{-(Z_1^{\text{meas}} - \frac{x}{r_1})}{r_1 \sigma_1^2} = 0 \quad \dots (9)$$

$$\therefore x = x_{\text{est}} = r_1 Z_1^{\text{meas}} \quad \dots (9a)$$

That means the value of x sorry that minimises the right hand term is found by simply taking the first derivative and settling the your setting the result to zero. That means, d/dx of this one is equal to 2 will come, but 0, 0 both side are right hand side is 0. So, in generally it will come minus Z_1 measure minus x upon r_1 that is in bracket divided by $r_1 \sigma_1$ square is equal to 0. This is equation 9. Solving this at for if you make that x is equal to x_{est} right estimated value.

Therefore x is equal to $x_{\text{estimated value}}$ will simply r_1 into Z_1 measure, this equation I have marked as a 9 a. So, for a simple voltmeter or ammeter you are getting the sa same result like b is equal to $i r$. Because Z_1 measure is nothing but the i and this is the r_1 and this is x is nothing but the b right. So here, actually 1 me only 1 meter is there and you are just trying to find out the true value of the voltage, so it is quiet straight forward right. But which is simply it is b is equal to $i r$; so this is you simple one.

(Refer Slide Time: 23:07)

Now, suppose now I have now we have say two ammeters, pay in parallel and one resistance is r_1 here one resistance is r_2 here, current measure by ammeter-1 is Z_1 measure and current measured by your ammeter-2 it is your Z_2 measure right. And this is the true value of the voltage that is v . We have to estimate that true value, and this ammeter has standard deviation σ_1 and this ammeter has standard deviation σ_2 right.

And that that error for this ammeter it is ζ_1 and for this one it is ζ_2 . So, it is simple parallel circuit two registers are connected in parallel right. And it an across that a voltage source is there that mean all three quantities are in parallel and these two ammeters measuring Z_1 measure and Z_2 measure the current flowing through the ammeter right.

So, it is a simple DC circuit, now assume that both r_1 and r_2 are known as before each meter reading as the sum of the true value and a random error right.

(Refer Slide Time: 24:11)

The slide displays two equations for measured values Z_1^{meas} and Z_2^{meas} in terms of true values Z_1^{true} and Z_2^{true} plus error terms η_1 and η_2 . The equations are grouped by a large right-facing curly bracket and labeled as equation (10). Below the equations, a text block explains that the errors are independent, zero-mean, normally distributed random variables with probability density functions.

$$\left. \begin{aligned} Z_1^{meas} &= Z_1^{true} + \eta_1 \\ Z_2^{meas} &= Z_2^{true} + \eta_2 \end{aligned} \right\} \dots (10)$$

Where the errors will be represented as independent zero mean, normally distributed Random Variables with probability density functions:

Now, we know from the same procedure Z_1 measure will be equal to Z_1 true plus η_1 and Z_2 measure will be Z_2 true plus η_2 . So, these two equations combined are marked as equation (10), where the errors will be represented as independent zero mean, normally distributed random variables with probability density functions.

So, it means that one measurement does not influence the other measurement; they are completely independent.

(Refer Slide Time: 24:53)

The slide shows the probability density functions (PDFs) for the error terms η_1 and η_2 . Each PDF is a Gaussian function centered at zero. The equations are grouped by a large right-facing curly bracket and labeled as equation (11). Below the equations, a text block states that the PDFs for the measured values Z_1^{meas} and Z_2^{meas} can be written as:

$$\left. \begin{aligned} \text{PDF}(\eta_1) &= \frac{1}{\sigma_1 \sqrt{2\pi}} \exp\left(-\frac{\eta_1^2}{2\sigma_1^2}\right) \\ \text{PDF}(\eta_2) &= \frac{1}{\sigma_2 \sqrt{2\pi}} \exp\left(-\frac{\eta_2^2}{2\sigma_2^2}\right) \end{aligned} \right\} \dots (11)$$

and as before we can write the probability density functions of Z_1^{meas} and Z_2^{meas} as:

So, therefore, PDF zeta 1 we can write, 1 upon σ_1 root over 2π x e to the power minus σ_1 square upon $2\sigma_1$ square zeta 1 square upon $2\sigma_1$ square. So, zeta 1 is Z_1 measured minus your Z_1 true value.

Similarly PDF zeta 2 is equal to 1 upon σ_2 root over 2π e to the power minus zeta 2 square upon $2\sigma_2$ square. So, zeta 2 is nothing, but z measure to minus your what you call that your Z true value divided by your 2 what that will zeta 2 and divided by $2\sigma_2$ square right. This is this equation combining equation 11 right and as before we can write the probability density function of Z_1 measure and Z_2 measure.

(Refer Slide Time: 25:41)

$$\rightarrow \text{PDF}(Z_1^{\text{meas}}) = \frac{1}{\sigma_1 \sqrt{2\pi}} \exp \left[\frac{-(Z_1^{\text{meas}} - \frac{x}{r_1})^2}{2\sigma_1^2} \right]$$

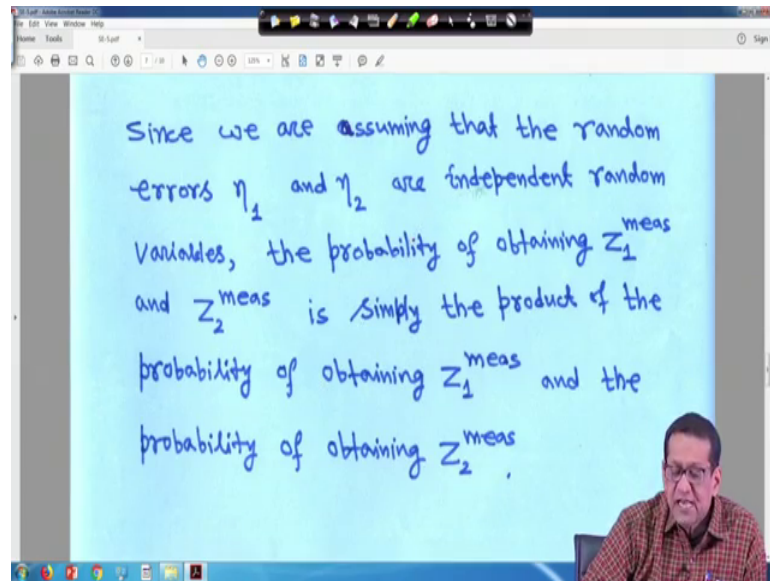

$$\rightarrow \text{PDF}(Z_2^{\text{meas}}) = \frac{1}{\sigma_2 \sqrt{2\pi}} \exp \left[\frac{-(Z_2^{\text{meas}} - \frac{x}{r_2})^2}{2\sigma_2^2} \right] \quad \dots (12)$$

The likelihood function must be the probability of obtaining the measurements Z_1^{meas} and Z_2^{meas}

So, in this case, if we do so, so PDF Z, PDF Z_1 measure is equal to 1 upon σ_1 root over 2π e to the power minus of Z_1 measure minus x upon r_1 whole square divided by $2\sigma_1$ whole square, is same as before that your Z_1 measure minus Z true and Z_2 is equal to it is a parallel circuit. So, Z_1 true will be x upon r_1 similarity it is a parallel circuit that Z_2 will be x upon r_2 right.

That is why, this PDF Z_1 measure is equal to 1 upon σ_1 root over 2π e to the power minus of Z_1 measure minus x upon r_1 whole square upon $2\sigma_1$ whole square right. Similarly PDF Z_2 measure will be 1 upon σ_2 root over 2π e to the power minus in bracket Z_2 measure minus x upon r_2 whole square upon $2\sigma_2$ square. This is equation this two equation is combined equation 12 right. Now we have to maximize the probability of Z_1 measure and Z_2 measure right.

(Refer Slide Time: 26:51)

Now, the likelihood function must be the probability of obtaining the measurements Z_1 measure and Z_2 measure right. Therefore, since we are assuming that the random errors η_1 and η_2 are independent random variables the probability of obtaining Z_1 measure and Z_2 measure is simply the product of the probability of obtaining Z_1 measure and the probability of obtaining Z_2 measure right. That means, probability of Z_1 measure and Z_2 measure is equal to probability of Z_1 measure into probability of Z_2 measure.

(Refer Slide Time: 27:13)

$$\begin{aligned} &\rightarrow \text{prob}(Z_1^{\text{meas}} \text{ and } Z_2^{\text{meas}}) = \text{prob}(Z_1^{\text{meas}}) \times \text{prob}(Z_2^{\text{meas}}) \\ &\rightarrow = \text{PDF}(Z_1^{\text{meas}}) \cdot \text{PDF}(Z_2^{\text{meas}}) \cdot dZ_1^{\text{meas}} \cdot dZ_2^{\text{meas}} \\ &\rightarrow = \text{PDF}(Z_1^{\text{meas}}) \text{PDF}(Z_2^{\text{meas}}) dZ_1^{\text{meas}} dZ_2^{\text{meas}} \\ &= \left[\frac{1}{\sigma_1 \sqrt{2\pi}} \exp\left\{-\frac{(Z_1^{\text{meas}} - \frac{x}{\gamma_1})^2}{2\sigma_1^2}\right\} \right] \times \left[\frac{1}{\sigma_2 \sqrt{2\pi}} \exp\left\{-\frac{(Z_2^{\text{meas}} - \frac{x}{\gamma_2})^2}{2\sigma_2^2}\right\} \right] \\ &\quad \times dZ_1^{\text{meas}} dZ_2^{\text{meas}} \dots (13) \end{aligned}$$

Because these two are independent, is equal to we can write that earlier we have seen probability of z measure is equal to in general PDF Z measure into d Z 1 measure. So, this one you can write PDF Z 1 measure d Z 1 measure into PDF Z 2 measure into d Z 2 measure right. Or we can right PDF Z 1 measure into PDF Z 2 measure then, d Z 1 measure into d Z 2 measure right. So, just let me reduce this volume little bit right. now this ok; sorry area.

So, just hold on. So, this one; that means, if you write if you write like this, then these two we can write that if you substitute the PDF Z 1 measure and PDF Z 2 measure expense your what you call expression. Then it will you will get 1 upon σ root 2 pi e to the power minus Z 1 measure minus x upon r 1 whole square upon 2 sigma 1 square into 1 upon σ 2 root 2 pi e to the power minus Z 2 measure minus x upon r 2 whole square upon 2 sigma 2 square into d Z 1 measure d Z 2 measure that is equation 13.

Actually here also what will do, that we got this expression right. So, we have to maximize the probability then ultimately what we have to do is we have to maximize the actually a your what you call PDF your Z 1 measure into PDF Z 2 measure. These two we have to maximize again we have to take the natural logarithm of this. I told you that maximizing the PDF function here is nothing but the maximizing of the logarithm your natural logarithm will take and that same function the \ln function right.

Thank you very much we will be back again.
